INFANT.

INFANT, in law, is a person under full age, and therefore subject to certain disabilities not affecting persons who have attained full age. The period of full age varies widely in different systems, as do also the disabilities attaching to nonage. In Roman law, the age of puberty, fixed at fourteen for males and twelve for females, was recognized as a dividing line. Under that age a child is under the guardianship of a tutor, but several degrees of infancy are recognized. The first is absolute infancy in the literal sense—speechlessness; after that, until the age of seven, a child is *infantiæ proximus;* and from the eighth year to puberty he is *pubertati proximus.* An infant in the last stage could, with the assent of his tutor, act so as to bind himself by stipulations; in the earlier stages he could not, although binding stipulations could be made to him in the second stage. After puberty, until the age of twenty-five years, a modified infancy was recognized, during which the minor's acts were not void altogether, but voidable, and a curator was appointed to manage his affairs. The difference between the tutor and the curator in Roman law was marked by the saying that the former was appointed for the care of the person, the latter for the estate of the pupil. These principles of course apply only to children who are *sui juris.* The *patria potestas*, so long as it lasts, gives to the father the complete control of the son's actions; and tutorship and curatorship were devices for protecting those who were free from the *potestas*, but unable by reason of infancy to control their own affairs. The right of the father to appoint tutors to his children by will (*testamentarii*) was recognized by the Twelve Tables, as was also the tutorship of the *agnati* (or legal as distinct from natural relations) in default of such an appointment. Tutors who held office in virtue of a general law were called *legitimi.* Besides and in default of these, tutors *dativi* were appointed by the magistrates. These terms are still used in much the same sense in modern systems founded on the Roman law, as may be seen in the case of Scotland noticed below.

By the law of England full age is twenty-one, and all minors alike are subject to incapacities. The period of twenty-one years is regarded as complete at the beginning of the day before the birthday: for example, an infant born on the first day of January attains his majority at the first moment of the 31st of December. The incapacity of an infant is designed of course for his own protection, and its general effect is to prevent him from binding himself absolutely by obligations. In the matter of contracts, the statement has generally passed current that an infant's contracts, except when they are binding for special reasons, are either void or voidable, *i.e.*, null, *ab initio*, or capable of being nullified by the infant at his choice. Contracts, for example, which cannot be beneficial to the infant are said to be absolutely void. A bond with a penalty is for this reason declared to be void. On the other hand, it is alleged by the more recent text-writers that the words void and voidable have not been carefully distinguished, and that a contract is often described as void when it is only meant that it is not binding. On this theory all the contracts of an infant might be described as voidable at his option except those few which are absolutely valid. On his voidable contracts an infant may sue if he chooses to do so, but may not be sued. Of the contracts of an infant which are binding *ab initio*, the most important are those relating to "necessaries." The word is used in an extended signification to cover "articles fit to maintain the person in the particular state, degree, and station in life in which he is." Whether a particular thing is necessary or not is a question of fact to be decided by a jury, but it is for the judge to say whether it is *prima facie* of a description such that it may be a necessary. It has been ruled by judges, without consulting the jury, that the following articles were not necessary:—expensive dinners supplied to an undergraduate in his private rooms; a pair of solitaire studs costing £25, and a goblet costing £15, for a baronet's son; a chronometer worth £68, for a lieutenant in the navy; ornaments to the value of £137. On the other hand, an undergraduate has been allowed a gold watch as a necessary; and liveries for an officer's servant, money paid to release an infant from ejectment or distress, and necessaries for an infant's wife have all been held to be necessaries of an infant. An object, in itself of a character to be pronounced a necessary, may in particular cases be declared not necessary, *e. g.*, if the infant is already supplied with things of the kind. A sealskin waistcoat may be a necessary to an infant of good fortune, but not if he has half a dozen such garments in his possession already. The person who supplies goods *prima facie* necessary to an infant must, it would seem, take the risk of their turning out to be unnecessary. An infant fraudulently passing himself off as of full age and contracting on that footing will be held bound in equity. The protection of infants extends sometimes to transactions completed after full age: the relief of heirs who have been induced to barter away their expectations is an example. "Catching bargains," as they are called, throw on the persons claiming the benefit of them the burden of proving their substantial righteousness; and, although the youth of the party charged is not an essential point, it is generally one of the facts relied on as showing undue influence.

At common law a bargain made by an infant might be ratified by him after full age, and would then become in all respects binding. Lord Tenterden's Act required the ratification to be in writing. But now by the Infants' Relief Act, 1874, "all contracts entered into by infants for the repayment of money lent or to be lent, or for goods supplied or to be supplied (other than contracts for necessaries), and all accounts stated, shall be absolutely void," and "no action shall be brought whereby to charge any person upon any promise made after full age to pay any debt contracted during infancy, or upon any ratification made after full age of any promise or contract made during infancy, whether there shall or shall not be any new consideration for such promise or ratification after full age." It has been held in a recent case that this action applies to promises of marriage, so that where an infant had promised marriage, and after attaining full age continued to recognize the promise, no action arose on the breach. But an actual contract of marriage may be lawfully made by persons under age. Marriageable age is fourteen in males and twelve in females. So, generally, an infant may bind himself by contract of apprenticeship or service. Since the passing of the Wills Act, an infant is unable to make a will. Infancy is in general a disqualification for public offices and professions, *e. g.*, to be a member of parliament or an elector, a mayor or burgess, a priest or deacon, a barrister or solicitor, etc.

The custody of an infant belongs in the first place, and against all other persons, to the father, who is said to be "the guardian of his children by nature and nurture;" and the father may by deed or will dispose of the custody or tuition of his children until the age of twenty-one. If the father is dead, and has appointed no testamentary guardian, the mother is recognized as "guardian by nature and nurture." But the children must be brought up in the father's religion, even when he has given no directions on the subject; and it appears that no agreement between husband and wife to the contrary effect will be sustained. When, however, the father has in his lifetime suffered the children to be educated in their mother's religion, he may be held to have waived his rights. The Court of Chancery is unwilling to embarrass itself by departing from the strict rule, and an instance is recorded of a child who had been educated from eight to fifteen in the tenets of the Plymouth Brethren being ordered by the court to be educated in the religion of the Church of England. The right of the father to the custody of the child will be enforced, except where he has been guilty of gross immorality, by writ of *habeas corpus*, as long as the child is within the age of nurture, which for males at least may be taken to be fourteen years. The infant then acquires a right of election. In two cases a boy over fourteen but under sixteen has been permitted by the court to choose, when the father had sued for the custody under a *habeas corpus*. In the case of female infants, the courts have held that they do not acquire the right of election till sixteen, following the statute of Philip & Mary which punishes the abduction of maidens under that age as a criminal offence. These rules do not apply to illegitimate children, as they are not under the legal guardianship of the putative father or the mother. The rights of the father or mother may be interfered with by the Court of Chancery under special circumstances, such as cruelty, immorality, etc. A recent Act (36 & 37 Vict. c. 12) gives power to the court to make orders for the mother of an infant under sixteen, to have or retain the custody of such infant, or to have access thereto, etc. The same statute legalizes agreements by the father to give up the custody and control of children to the wife. The Divorce Court has also very extensive powers of regulating the custody and maintenance of children, in exercising which it observes the same limits of age as the courts of law and chancery.

There is not at common law any corresponding obligation on the part of either parent to maintain or educate the children. The legal duties of parents in this respect are only those created by the poor laws and the Elementary Education Act. In the case, however, of debts contracted by a child for necessaries, the authority of the father would, to use a common phrase, be "easily implied."

Besides the natural guardianship of parents, children may in various other ways come under the authority of guardians. A recent author gives the following as a complete list of guardians:—guardian in chivalry, in socage, in nature, by nurture, by election of the infant, by statute (4 Philip & Mary c. 8, 12 Chas. II. c. 24), by custom, by appointment of the ecclesiastical courts and of the Court of Chancery, foreign guardians, and guardians *ad litem* (Simpson's *Law of Infants*, London, 1875). Some of these have already been noticed, and others are obsolete or nearly so. The Act of Chas. II. enables the father to appoint a testamentary guardian to his children during infancy or any less period, who shall have the charge of the infant's real and personal estate. The Act is not to prejudice any customary guardianship, such as that of the City of London, where, according to ancient but now disused custom, the goods and lands of the orphans of freemen are in the custody of the lord mayor and aldermen in their court of orphans. By the custom of Kent, and by the special customs of certain manors, the lord has the right of appointing guardians to infant tenants. Guardianship by socage extends only to lands of socage tenure, and belongs to the next of blood of the infant, other than those who might succeed to the estate when the infant dies. It ends when the infant reaches the age of fourteen; after that age, or before if there was no guardian, infants were formerly allowed to elect a guardian, but that practice is now superseded by the action of the Court of Chancery, which appoints guardians in all cases where it is for the benefit of the infants to do so. An infant under a guardian appointed by the Court of Chancery is properly a "ward of court," but the term is also applied to infants brought under the authority of the court although no guardian be appointed. The office and duty of the guardian extend to the custody and control of the infant, to his education, maintenance, and advancement out of any property that may be available therefor, and to the prevention of improper and disparaging marriages. The office of guardian is strictly a trust, the ordinary duties and responsibilities of a trustee with respect to property being accompanied by peculiar rights and duties with respect to the person of the *cestui que trust.* He must act in all cases for the benefit of the infant, and may not put himself into any position in which his interest would be hostile to that of the infant. The Court of Chancery has full jurisdiction over guardians of every kind, whether appointed by itself or not, and if it cannot actually dismiss a testamentary guardian, it may supersede him and entrust the charge of the infant to some other person on proper cause being shown (see TRUSTEE).

An infant is liable to a civil action for torts and wrongful acts committed by him. But, as it is possible sometimes so to shape the pleadings in an action as to make what is in substance a right arising out of contract take the form of a right arising from civil injury, care is taken that an infant in such a case shall not be held liable. With respect to crime, mere infancy is not a defence, but a child under seven years of age is presumed to be incapable of committing a crime, and between seven and fourteen his capacity requires to be affirmatively proved. After fourteen an infant is *doli capax.*

The law of Scotland follows the leading principles of the Roman law. The period of minority (which ends at twenty-one) is divided into two stages, that of absolute incapacity (until the age of fourteen in males, and twelve in females), during which the minor is in pupilarity, and that of partial incapacity (between fourteen and twenty-one), during which he is under curators. The guardians (or tutors) of the pupil are either tutors-nominate (appointed by the father in his will); tutors-at-law (being the next male agnate of twenty-five years of age), in default of tutors-nominate; or tutors-dative, appointed by royal warrant in default of the other two. No act done by the pupil, or action raised in his name, has any effect without the interposition of a guardian. After fourteen, all acts done by a minor having curators are void without their concurrence. Every deed in nonage, whether during pupilarity or minority, and whether authorized or not by tutors or curators, is liable to reduction on proof of "lesion," *i. e.*, of material injury, due to the fact of nonage, either through the weakness of the minor himself or the imprudence or negligence of his curators. Damage in fact arising on a contract in itself just and reasonable would not be lesion entitling to restitution. Deeds in nonage, other than those which are absolutely null *ab initio*, must be challenged within the *quadriennium utile*, or four years after majority.

In the United States, the principles of the English common law as to infancy prevail, generally the most conspicuous variations being those affecting the age at which women attain majority. In many States this is fixed at eighteen. There is some diversity of practice as to the age at which a person can make a will of real or personal estate. (E. R.)

INFANTICIDE. The history of infanticide as an archaic institution has already been referred to in the article FOUNDLING HOSPITALS (vol. ix. p. 425). Children of both sexes were sacrificed as religious offerings. Indeed, in some cases, *e.g.*, in expiations for sacrilege, the boy, as being the nobler child, was preferred. But what may be called the normal infanticide of early society was probably confined to girls. The custom is in certain places and for certain periods explained by the system of exogamy; but much more generally, as in China at the present day, it is simply an illustration of what Malthus would call a "positive check," the reckless propagation of children far outrunning the means of subsistence which the energy of the parents can provide. Infanticide still survives among many savage races; and, where the necessity for strong warriors is felt, a selection is sometimes made of the weaker children for destruction. But this political element seldom enters into the custom. It is because girls cannot provide for themselves that they are killed.

More complex were the leading forms of infanticide in India, now suppressed by the wise action of the British Government. The practice, though forbidden by both the Vedas and the Koran, prevailed among the Rájputs and certain of the aboriginal tribes. Among the aristocratic Rájputs, for example, it was thought dishonorable that a girl should remain unmarried. Moreover, a girl may not marry below her caste; she ought to marry her superior, or at least her equal. This reasoning was obviously most powerful with the highest castes, in which, accordingly, the disproportion of the sexes was painfully apparent. But assuming marriage to be possible, it is ruinously expensive to the bride's father. He has to make gifts of money, clothes, jewels, and sweetmeats to the bridegroom's relatives; and when the marriage ceremony comes, he has, chiefly owing to the exactions of the Bráhmans and Bhats or minstrels, to face a lavish expenditure on feasts which in the case of some rájás has been known to reach more than £100,000. To avoid all this, the Rájput killed a certain proportion of his daughters,—sometimes in a very singular way. A pill of tobacco and bhang might be given to the new-born child to swallow; or it was drowned in milk; or the mother's breast was smeared with opium or the juice of the poisonous *Datura*. A common form was to cover the child's mouth with a plaster of cow-dung before it drew breath. Infanticide was also practised to a small extent by some sects of the aboriginal Kandhs, and by the poorer hill tribes of the Himalayas. Where infanticide occurs in India, though it really rests on the economic facts stated, there is usually some poetical tradition of its origin. The measures against the practice were begun towards the end of the 18th century by Jonathan Duncan and Major Walker. They were continued by a series of able and earnest officers during the present century. One of its chief events, representing many minor events, was the Umritsur durbar of 1853, which was arranged by the late Lord Lawrence. At that great meeting the chiefs residing in the Punjab and the trans-Sutlej states signed an agreement engaging to expel from caste every one who committed infanticide, to adopt fixed and moderate rates of marriage expenses, and to exclude from these ceremonies the minstrels and beggars who had so greatly swollen the expense. According to the present law, if the female children fall below a certain percentage in any tract or among any tribe in northern India where infanticide formerly prevailed, the suspected village is placed under police supervision, the cost being charged to the locality. By these measures, together with a strictly enforced system of reporting births and deaths, infanticide has been almost trampled out; although some of the Rájput clans keep their female offspring suspiciously close to the lowest average which secures them from surveillance.

The modern crime of infanticide shows no symptom of diminution in the leading nations of Europe. In all of them it is closely connected with illegitimacy in the class of farm and domestic servants. The crime is generally committed by the mother for the purpose of completing the concealment of her shame, and in other cases, where shame has not survived, in order to escape the burden of her child's support. The paramour sometimes aids in the crime, which is not confined to unmarried mothers. The ease with which affiliation orders are obtained in Great Britain must save the lives of many children. In France, where the inquiry into paternity is forbidden, a controversy still goes on as to the influence of hospitals for "assisted children," which are said to save life at the expense of morality. It seems certain that the great administrative change involved in closing the "tour" at these hospitals has not perceptibly affected infanticide in France. The laws of the European states differ widely on this subject,—some of them treating infanticide as a special crime, others regarding it merely as a case of murder of unusually difficult proof.

In the law of England, the inexcusable killing of infants is theoretically murder. The infant must of course be a human being in the legal sense; and "a child becomes a human being when it has completely proceeded in a living state from the body of its mother, whether it has breathed or not, and whether it has an independent circulation or not, and whether the navel string is severed or not; and the killing of such a child is homicide when it dies after birth in consequence of injuries received before, during, or after birth." A child in the womb, or in the act of birth, though it may have breathed, is therefore not a human being, the killing of which amounts to homicide. The older law of child murder under a statute of James I. consisted of cruel presumptions against the mother, and it was not till 1803 that trials for that offence were placed under the ordinary rules of evidence. There now is a presumption, said to be based on considerations of humanity, that every new-born child found dead is born dead until the contrary is very clearly shown. It is the opinion of the most eminent of British medical jurists that this presumption has tended to increase infanticide. Apart from this, the technical definition of human life has excited a good deal of comment and some indignation. The definition allows many wicked acts to go unpunished. The experience of assizes in England shows that many children are killed when it is impossible to prove that they were wholly born. The distinction taken by the law has probably by this time reached the minds of the class to which most of the unhappy mothers belong. Partly to meet this complaint, it was suggested to the Royal Commission of 1866 that killing during birth, or within seven days thereafter, should be an offence punishable with penal servitude. The second complaint is of an opposite character,—partly that infanticide by mothers is not a fit subject for capital punishment, and partly that, whatever be the intrinsic character of the act, juries will not convict or the executive will not carry out the sentence. Earl Russell gave expression to this feeling when he proposed that no capital sentence should be pronounced upon mothers for the killing of children within six months after birth.

It is a statutory offence, under 24 & 25 Vict. c. 100, to administer poison or any noxious thing to a woman with child with intent to procure her miscarriage, or to use any instrument for the same purpose, the maximum punishment being penal servitude for life. The previous law had drawn the distinction of "quick with child," and in such cases had punished capitally. It was a very old controversy among the philosophers and physicians of antiquity, when the fœtus ceased to be *pars viscerum matris* and became "vital," or, as it was afterwards called, "animate." The law has not yet succeeded in putting down the degraded and wicked trade in abortion. There can be no doubt from the French and American treatises of Gallard and Storer that the crime prevails extensively, and even in classes of society in which infanticide proper would not be thought of without a shudder.

Under the same statute it is a misdemeanor punishable by two years' imprisonment with hard labor, as a maximum, to endeavor to conceal the birth of a child by any secret disposition of its dead body, whether the child died before, after, or at its birth. This does not apply to very premature births, where it was impossible that the fœtus should be alive. But it does apply to all those numerous cases where the child's body, without being actually hidden, is placed where it is not likely to be found except by accident, or upon search. Lastly, under the same statute it is a misdemeanor punishable by five years' penal servitude, as a maximum, to abandon or expose a child under the age of two years, so as to endanger its life, or to inflict permanent injury, actual or probable, upon its health.

It is difficult to say to what extent infanticide prevails in the United Kingdom. At one time a large number of children were murdered in England for the mere purpose of obtaining the burial money from a benefit club.[1] In 1871 the House of Commons found it necessary to appoint a select committee "to inquire as to the best means of preventing the destruction of the lives of infants put out to nurse for hire by their parents." The trials of Margaret Waters and Mary Hall called attention to the infamous relations between the lying-in houses and the baby-farming houses of London. The form was gone through of paying a ridiculously insufficient sum for the maintenance of the child. "Improper and insufficient food," said the committee, "opiates, drugs, crowded rooms, bad air, want of cleanliness, and wilful neglect are sure to be followed in a few months by diarrhœa, convulsions, and wasting away." These unfortunate children were nearly all illegitimate, and the mere fact of their being hand-nursed, and not breast-nursed, goes some way (according to the experience of the Foundling Hospital and the Magdalene Home) to explain the great mortality among them. Such children, when nursed by their mothers in the workhouse, generally live. The practical result of the committee of 1871 was the Act of 1872, 35 & 36 Vict. c. 38, which provides for the compulsory registration of all houses in which more than one child under the age of one year are received for a longer period than twenty-four hours. No license is granted by the justices of the peace, unless the house is suitable for the purpose, and its owner a person of good character and able to maintain the children. Offences against the Act, including wilful neglect of the children even in a suitable house, are punishable by a fine of £5 or six months' imprisonment with or without hard labor.

The law of Scotland also treats the unlawful killing of completely born infants as murder. In such cases a verdict of culpable homicide is usually returned, the punishment being entirely in the discretion of the court. Still more commonly the charge of concealment of pregnancy is made under the Act 49 Geo. III. c. 14, the maximum punishment being two years' imprisonment. It must be shown that the woman concealed her condition during the whole period of pregnancy, and did not call for help at the birth. Unlawfully procuring abortion, whether by drugs or instruments, is also a crime known to the common law of Scotland, the punishment being penal servitude or imprisonment according to circumstances. In a variety of cases, which do not admit of general statement, convictions have also been obtained against parents of exposing and deserting children or placing them in danger, and of cruel and unnatural treatment and neglect.

Infanticide will have to be further considered under the heading MEDICAL JURISPRUDENCE. For that branch of the subject the works of Tardieu and Taylor are the most important and recent authorities. See also Whitehead *On Abortion and Sterility*, and the works of Gallard and Storer already referred to.

Bibliography.—Besides a very large number of theses and special dissertations, and the chapters on the subject in the leading works in medical jurisprudence, the following are the most important works on infanticide. Ploucquet, *Commentarius Medicus in processus criminales super homicidio, infanticidio*, etc., 1736; W. Hunter, *Uncertainty of the Signs of Murder in Bastard Children;* Olivard, *De l'infanticide et des moyens que l'on employe pour le constater*, Paris, 1802; Mahon, *An Essay on the Signs of Murder in New-Born Children*, translated by Johnson, Lancaster, 1813; Arrowsmith, *Medico-legal Essay on Infanticide*, Edin., 1828; Cummin, *Proofs of Infanticide Considered*, London, 1836; Ryan, *Child Murder in its Sanitary and Social Bearings*, 1858, and *Infanticide, its Law, Prevalence, Prevention, and History*, London, 1862; Kunze, *Der Kindermord, historisch u. kritisch dargestellt*, Leipsic, 1860; Greaves, *Observations on some of the causes of Infanticide*, Manchester, 1863, and *Observations on the Laws referring to Child Murder and Criminal Abortion*, Manchester, 1864; Storer and Heard, *Criminal Abortion, its Nature, Evidence, and Law*, Boston, 1868; Tardieu, *Étude méd.-lég. et clinique sur l'avortement*, Paris, 1864, and *Étude méd.-lég. sur l'infanticide*, Paris, 1880; Toulmouche, *Études sur l'infanticide et la grossesse cachée ou simulée*, Paris, 1875; Gallard, *De l'avortement au point de vue med.-leg.*, Paris, 1878. There are several works describing Indian infanticide. The best known is *Infanticide, its Origin, Progress, and Suppression*, London, 1857, by J. Cave Browne. See also the works of Moore, Cormack, and Wilson. (W. C. S.)

INFANTRY. See ARMY.

INFINITESIMAL CALCULUS.

HISTORICAL INTRODUCTION.

THE mathematical and physical sciences owe their present great development to the introduction of the infinitesmal calculus. The power, for example, of that calculus as an instrument of analysis has vastly extended the science of geometry, so that the investigations of the ancient Greeks go but a short way into the field of knowledge which has been laid open by the modern method; the discoveries of Archimedes and Apollonius are now easy deductions from its more extended results.

---

[1] See *Report on the Sanitary Condition of the Laboring Classes*, "Supplementary Report on Interment in Towns," by Edwin Chadwick (*Parl. Papers*, 1843, xii. 395); and *The Social Condition and Education of the People*, by Joseph Kay, 1850.

So long as the early geometers confined their speculations to the comparison of the areas of rectilinear figures they encountered little difficulty. They readily showed that the determination of the area of any such figure can be reduced to that of a rectangle, or of a square, and thus be completely effected. This process of finding areas was named the "method of quadratures." It failed, however, when they attempted to determine the areas bounded by curved lines, or the surfaces of the elementary solids such as the right cone and the sphere. In treating of these the ancients found it necessary to introduce new notions and modes of demonstration into geometry, and the difficulty of comparing the areas of curvilinear with those of rectilinear figures gave rise to the "method of exhaustions." The fundamental principle of this method consists in conceiving the continual approach of two varying magnitudes to a fixed intermediate magnitude, with which they never become identical, though they may approach it to within less than any assignable difference. For example, a polygon may be inscribed in a circle, and another circumscribed to it, each differing from it by less than any assignable area; hence the ancients may have concluded that areas of circles have to each other the same ratio as the similar polygons inscribed in or circumscribed to them,—that is, the ratio of the squares of the radii. But, as this kind of proof was of a different nature from that by which the more elementary doctrines were established, the Greek geometers fortified it by a *reductio ad absurdum*,—proving, in the above example, that the square of the radius of one circle is to that of another as the area of the former is to a space which is neither less nor greater than the latter, and therefore exactly equal to it.

Archimedes.

By the aid of this method Archimedes arrived at his great geometrical discoveries. He determined that the ratio of the circumference to the diameter of a circle lies between $3\frac{1}{7}$ and $3\frac{10}{71}$, by considering the regular polygons of ninety-six sides which may be inscribed in or circumscribed to the circle. He proved that the area of a segment of a parabola cut off by any chord equals two-thirds of a parallelogram included between the chord and the parallel tangent to the curve. He determined the quadrature of the ellipse. In the curves named after him the "spirals of Archimedes," he showed how to draw a tangent at any point, and also determined the area of any portion.

In space of three dimensions, Archimedes proved that the surface of a sphere equals four times that of one of its great circles, that the surface of a spherical cap is equal to the area of a circle the length of whose radius is the distance from the vertex of the cap to any point on its bounding circle; that a sphere has a volume which is two-thirds of that of a cylinder circumscribed to it, and that their surfaces are in the same ratio. Further, the same method of exhaustions furnished Archimedes with the cubature of conoids and spheroids, as he termed surfaces generated by the revolution of the parabola, the hyperbola, and the ellipse.

Kepler.

During nearly two thousand years no new method enabled mathematicians to rise to a higher generality than that attained in the works of the great Greek geometers. The celebrated Kepler was the first to extend the results of Archimedes. In his treatise entitled *Nova Stereometria Doliorum; accessit stereometriæ Archimideæ supplementum* (1615),[1] he discussed a number of solids of revolution,—for example, those formed by the revolution of a conic section about any ordinate, or a tangent at the vertex, or any line within or without the curve. Thus he considered some ninety new solids, and proposed problems concerning them; of these problems he resolved only a few of the most simple. In this treatise he introduced for the first time the name and notion of "infinity" into the language of geometry. Thus, he considered a circle as composed of an "infinite" number of triangles, having their common vertex at the centre, and forming the circumference by their bases. In like manner he regarded a cone as composed of an infinite number of pyramids, having their vertices at its vertex, and standing on an infinite number of triangular bases, bounded by the circular base of the cone. It may also be noted that Kepler was the first to observe that the increment of a variable—the ordinate of a curve, for example—is evanescent for values infinitely near a maximum or minimum value of the variable. This remark contains the germ of the rule for determining "maxima" and "minima," given by Fermat about twenty years subsequently.

Cavalieri.

Several years after Kepler had given his method of determining volumes of revolution, another celebrated theory, of a similar kind,—the "geometry of indivisibles" (1635) of Cavalieri, professor of geometry at Bologna,—marks an epoch in the progress which science has made in modern times. In this work lines were considered as composed of an infinite number of points, surfaces of lines, and solids of surfaces. For example, if the perpendicular of a triangle be divided into an infinite number of equal parts, and through each point of division a line be drawn parallel to the base and terminated by the sides, then, according to Cavalieri, we may consider the area of the triangle as the sum of all these parallel lines, regarded as its elements. Again, as these parallels form a series in arithmetical progression, of which the first term is zero, this sum is represented by half the product of the last term and the number of terms. Now the base is the last term, and the altitude measures the number of terms; thus he deduced the ordinary expression for the area of a triangle. Cavalieri applied his method to a number of problems, such as finding the volumes of pyramids, the areas of certain simple curves of the parabolic species, the determination of centres of gravity, etc.; and it is remarkable that he was the first who gave an accurate demonstration of the well-known properties of the centre of gravity, originally announced by Pappus, but commonly called Guldin's theorems. It is accordingly to Cavalieri, and not to Guldin, that the credit is due of having made the first advance beyond Pappus. Cavalieri's method is analogous to that employed in the integral calculus, the "indivisible" being that which has since been styled the "differential element" of the integral.

Pascal.

The method of Cavalieri was severely criticised by some of his contemporaries, more especially by Guldin. They alleged that, since a line has no breadth, no number of right lines, however great, when taken together, could make up a plane area. This objection was answered by Cavalieri; but the reply was stated in the clearest form by Pascal, who observed (letter to M. de Carcavi, 1658) that the method of indivisibles possessed all the rigor of that of exhaustions, from which it differed only in the manner of expression, and that, when we conceive an area as a sum of a system of parallel ordinates, we mean in reality an indefinite number of rectangles under the several ordinates, and the small equal portions into which we conceive the common perpendicular to these ordinates to be divided. This passage is remarkable—as was well observed by Carnot—as it shows that the notion of mathematical infinity, as now employed, was not strange to the geometers of that time; for it is clear that Pascal employed the word "indefinite" in the same signification as we now attach to the word "infinite," and that he called "small" that which is now called "infinitely small," also that he neglected these small quantities in comparison with finite quantities—thus he regarded as simple rectangles the small portions of the area of the curve comprised between two consecutive ordinates, neglecting the small triangles which have for their bases the differences of these ordinates. Carnot adds that no person attempted to reproach Pascal with want of rigor in his demonstrations.

---

[1] This work is enlarged from his earlier *Stereometria Doliorum Vinariorum* (1605), which originated in a dispute with a seller of wine as to the proper method of gauging the contents of a cask. This accounts for its strange title.

Pascal applied the method of Cavalieri with eminent success to the investigation of properties of the cycloid, and other problems. His researches, according to D'Alembert, closely approach to the integral calculus, and form the connection between the methods of Archimedes and of Newton.

Wallis. The most important application, however, of Cavalieri's method was that of Wallis, Savilian professor at Oxford, who, in 1655, gave an admirable specimen of this method in his *Arithmetica Infinitorum, sive nova Methodus inquirendi in Curvilinearum Quadraturam.* Pursuing Cavalieri's views, he reduced the problem of finding the areas of a large number of curves, and the volumes of solids of revolution, to the summation of the powers of the terms of arithmetical series, consisting of an infinite number of terms,—or rather to the determination of the ratio of the arithmetical mean of all such powers of the terms to the like power of the last term.

For example, in the series of square numbers 0, 1, 4, 9, 16, etc., the ratio of the mean to the last is, for the first three terms, $\frac{0+1+4}{4+4+4}=\frac{1}{3}+\frac{1}{12}$; for the first four, $\frac{0+1+4+9}{9+9+9+9}=\frac{1}{3}+\frac{1}{18}$; for the first five, $\frac{0+1+4+9+16}{16+16+16+16+16}=\frac{1}{3}+\frac{1}{24}$; in like manner the next fraction is $\frac{1}{3}+\frac{1}{30}$. Hence Wallis noticed that the fractions approach nearer and nearer to $\frac{1}{3}$; and, as the denominators in the fractions $\frac{1}{12}$, $\frac{1}{18}$, $\frac{1}{24}$, $\frac{1}{30}$ form an arithmetical series, with a common difference 6, it follows that, when the number of terms is indefinitely increased, the resulting fraction becomes ultimately $\frac{1}{3}$.

Wallis applied the same method to the series 0, 1^3, 2^3, 3^3, etc., and found without difficulty that the aforesaid ratio is $\frac{1}{4}$ in this case; and so generally. He also introduced into analysis the notation of fractional indices instead of radicals, and extended his method of summation to series proceeding by fractional powers of the natural numbers, 1, 2, 3, etc. Wallis was enabled by these principles to obtain the areas of many curves, and the volumes of solids which had not been previously found. He also, by aid of this method, combined with the principles of "interpolation," arrived at his well-known expression for π, viz.:

$$\frac{\pi}{4}=\frac{2\cdot4}{3\cdot3}\cdot\frac{4\cdot6}{5\cdot5}\cdot\frac{6\cdot8}{7\cdot7}\cdot\ .\ .\ .\ .\ .$$

Again, in his treatise *De Curv. rectif.* (1659), Wallis showed that certain curves were capable of being "rectified," or that straight lines might be found to which they were exactly equal, a remark which was very soon verified by a young English mathematician, William Neil, who, by Wallis's method, obtained in 1660 the length of any arc of a semicubical parabola. This is the first curve that was rectified. The cycloid is the second; its rectification was effected by Sir C. Wren (*Phil. Trans.*, 1673). The methods we have thus far considered were more especially precursory to the integral calculus, having mainly reference to the quadrature of curves and cubature of solids. We now propose to consider the question of tangents to curves, in which the differential calculus may be said to have originated.

Descartes. The great discovery of Descartes in his application of algebra to geometry (1637) imparted to the latter science the character of abstraction and generality which distinguishes modern from ancient geometry. By it the study of curves was brought under the domain of analysis, and instead of investigation being restricted to particular properties of a few isolated curves, as it had been hitherto, general views and methods applicable to all curves were introduced.

Hence the general problem of drawing tangents to curved lines started immediately into prominence. It was found necessary to depart from the definition of tangents given by the ancient geometers, and to consider them in other points of view. A tangent, accordingly, came to be regarded either (1) as a secant of which the points of intersection became coincident; or (2) as the prolongation of the element of the curve, regarded as a polygon of an infinite number of sides; or (3) as the direction of the resultant motion by which the curve may be described. The first view was that of Descartes and Fermat; the second was introduced by Barrow, who thus simplified the method of Fermat; and the third was that of Roberval.

Descartes's method of drawing a tangent consisted in supposing a circle (whose centre he placed on the axis of x) to cut the curve in two points; then, if the radius of the circle be supposed to decrease, *its centre remaining fixed*, so that the points of section approach nearer and nearer and finally coincide, the circle will touch the curve; thus, by aid of the equation of the curve, the problem was reduced to one of finding the condition of equal roots in an equation. This method is remarkable as being the first general process of applying analysis to the problem of tangents; at the same time it is only capable of practical application in a small number of simple cases.

Many years subsequently (*Act. Erud. Lips.*, 1691) John Bernoulli extended Descartes's method with success to the problem of finding the centre of curvature and the equation of the evolute of an algebraic curve. In his application he supposed the centre of a circle taken on the normal to a curve, and *the centre to vary* until *three* of the points of intersection of the circle with the curve became coincident, *i.e.*, so that the resulting equation should have three equal roots. Thus, for example, he showed, without difficulty, that the evolute of a parabola was a semicubical parabola. He also remarked that, when four roots coincide, the centre of curvature becomes a cusp on the evolute.

It should also be noticed that we owe to Descartes the general method of drawing a tangent to a roulette. This was given by him in a letter to Mersenne (Aug. 23, 1638), from which we take the following extracts:—"I have been very glad to see the questions which you say that the geometers, even M. Roberval, whom you esteem the principal of them, confess that they cannot solve; for in investigating them I may discover whether my analysis is better than theirs. The first of these questions is that of drawing tangents to curves described by a roulette motion. My solution is as follows. If a rectilinear polygon be conceived to roll on a right line, the curve described by any one of its points will be composed of a number of arcs of circles, and the tangent at any point on one of these arcs is perpendicular to the line drawn from the point to that in which the polygon is in contact with the base, when describing the arc. Consequently, if we consider a rolling curve as a polygon of an infinite number of sides, we see clearly that the roulette traced by any point must possess the same property; that is to say, the tangent at any of its points is perpendicular to the right line connecting it with the point of contact of the rolling curve and its base." In this we perceive that Descartes gave a genuine and most important application of the infinitesimal method.

Again, Descartes first introduced the method of indeterminate coefficients into analysis,—a principle, as was ably shown by Carnot, which is of itself sufficient to establish, by ordinary algebra, the fundamental principles of the infinitesimal calculus.

Fermat. The method of Fermat for drawing tangents was based on his method of maxima and minima. This latter was founded, as already observed, on a principle of Kepler's, viz., that, whenever a magnitude attains a maximum or minimum, its increment or diminution, for a very small change in the variable on which it depends, becomes evanescent. Accordingly, to determine the maximum or minimum of any function of x, Fermat substituted $x+e$ instead of x, and equated the two consecutive values of the function; then, removing the common terms, and dividing by e, he made $e=0$, and obtained an equation for determining the maximum or minimum value.

Thus, adopting the modern notation, let $y=f(x)$, and $y_1=f(x+e)$, then $f(x+e)-f(x)=0$. Dividing by e,

$$\frac{f(x+e)-f(x)}{e}=0;$$

hence $f'(x)=0$.

Thus the roots of the derived equation, $f'(x)=0$, correspond to the maximum or minimum values of $f(x)$. Consequently we see that Fermat's rule agrees with that of the differential calculus, and in fact is the method of the calculus as applied to such cases.[1]

In consequence of Fermat's both having introduced the conception of an infinitely small difference, and also having arrived at the principle of the calculus for determining maxima and minima, it was maintained by Laplace, Lagrange, Fourier, and other eminent French mathematicians that Fermat ought to be regarded as the first inventor of the differential calculus. In reply to this we need but introduce the remark of their distinguished countryman Poisson, "that this calculus consists in a system of rules proper for finding the differentials of all functions, rather than in the use which may be made of these infinitely small variations in the solution of one or two isolated problems" (*Mém. de l'Acad. des Sci.*, 1831).

Fermat seems to have given no general demonstration of his method, but contented himself with giving particular applications of it to some problems of maxima and minima, as well as to finding the tangents to and the centres of gravity of a few curves.

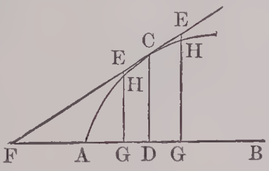

Fig. 1.

Fermat applied his method to drawing a tangent as follows:—

Suppose CD (fig. 1) the ordinate, and CF the tangent at the point C in a curve, meeting the axis AB in F; from E, a near point on CF, draw an ordinate EG; then

$$\frac{\mathrm{CD}}{\mathrm{DF}}=\frac{\mathrm{EG}}{\mathrm{GF}}>\frac{\mathrm{HG}}{\mathrm{GF}}, \text{ if the curve be concave to the axis,}$$

and $$\frac{\mathrm{CD}}{\mathrm{DF}}<\frac{\mathrm{HG}}{\mathrm{GF}}, \text{ if the curve be convex.}$$

Hence, in either case, the ratio of the ordinate CD to the subtangent DF is a maximum or a minimum relatively to the ratio for a near ordinate HG to GF, the abscissa measured from F, the foot of the tangent.

Accordingly, if $\mathrm{CD}=y$, $\mathrm{HG}=y_1$, and $\mathrm{DF}=t$, we have, by the method of maxima and minima,

$$\frac{y}{t}=\frac{y_1}{t\pm e}.$$

It is easily seen that this method furnishes the ordinary value for the subtangent, as obtained by infinitesimals; for, denoting by x, y the co-ordinates of C, let $t=\mathrm{FD}$, $\mathrm{DG}=dx$, $y_1=y+dy$, and we have

$$\frac{y}{t}=\frac{y+dy}{t+dx}, \qquad \therefore t=y\frac{dx}{dy}$$

from which the subtangent t can be obtained.

The method of Fermat was improved and extended by an Italian, Cardinal Ricci, in his *Geometrica exercitatio* (1666). Ricci was the first who showed that, if $(a-x)^m x^n$ is a maximum, we must have

$$x=\frac{na}{m+n}.$$

This he easily established when m and n are integers, from the principle that if a magnitude be divided into r *equal* parts, their continued product is greater than that obtained by dividing it into r parts in any other manner.

The following application, as given by him, to the curve $y^m=px^n$, $m>n$, will help to illustrate this method of drawing tangents. To draw the tangent at C (fig. 1) take $\mathrm{AF}:\mathrm{AD}=m-n:n$, and join FC; then FC touches the curve at C.

For the product $\mathrm{AF}^{m-n}\mathrm{AD}^n$ is a maximum by the preceding lemma; hence the product $\mathrm{AF}^{m-n}\mathrm{AG}^n$ is not a maximum for the line FG; consequently

$$\frac{\mathrm{AF}^{m-n}\mathrm{AD}^n}{\mathrm{FD}^m}>\frac{\mathrm{AF}^{m-n}\mathrm{AG}^n}{\mathrm{FG}^m}, \quad \therefore \left(\frac{\mathrm{AD}}{\mathrm{AG}}\right)^n>\left(\frac{\mathrm{FD}}{\mathrm{FG}}\right)^m;$$

but, from the equation of the curve,

$$\left(\frac{\mathrm{AD}}{\mathrm{AG}}\right)^n=\left(\frac{\mathrm{CD}}{\mathrm{HG}}\right)^m;$$

also $$\frac{\mathrm{FD}}{\mathrm{FG}}=\frac{\mathrm{CD}}{\mathrm{EG}}, \quad \therefore \frac{\mathrm{CD}}{\mathrm{HG}}>\frac{\mathrm{CD}}{\mathrm{EG}}, \text{ or } \mathrm{EG}>\mathrm{GH};$$

i. e., the point E falls outside the curve. In like manner it can be shown that any other point on CF lies outside the curve, and consequently CF touches the curve at C.

Barrow.

Barrow, Newton's predecessor in the Lucasian chair of mathematics at Cambridge, simplified and extended the method of Fermat, and advanced a step further in the development of the infinitesimal method, by the introduction of two infinitesimals instead of one in the problem of drawing a tangent. His method was as follows:—Let x, y be the co-ordinates of a point P on a curve (fig. 2), and take Q an adjacent point; let $e=\mathrm{PR}=\mathrm{MN}$ be the increment of x, and $a=\mathrm{QR}$ the increment of y; then, substituting $x+e$ for x, and $y+a$ for y, in the equation of the curve, subtracting the equation of the curve for the original values, and rejecting all terms of the second and higher degrees in a and e, he obtained the limiting value of $a:e$, or of PM : MT, thus determining the value of the subtangent. The triangle PQR, which has for its sides the elements of the curve, of the abscissa, and of the ordinate, has been called Barrow's *differential triangle.*

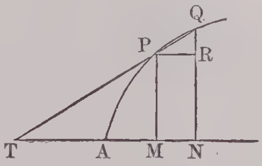

Fig. 2.

The elements which Barrow represented by a and e Leibnitz subsequently styled dy and dx, the differentials of the ordinate and abscissa of the point on the curve. Thus Barrow anticipated the methods of Leibnitz and Newton of drawing tangents, so far as rational algebraic curves were concerned. Barrow's researches were delivered in his professorial lectures in 1664, 1665, and 1666, and were published in 1670, under the title of *Lectiones Mathematicæ.*

Roberval.

The method of tangents of Roberval is based on the conception of the composition of motions, recently introduced by Galileo into mechanics, and depends on finding, from the properties of the curve, the different components of the motion of the point at which the tangent is required. The direction of the resultant of these motions determines that of the tangent. This method bears an analogy to Newton's method of "fluxions," but is very limited in its application on account of the impossibility of applying it except in a few cases. Roberval applied it successfully to the following curves—the parabola, hyperbola, ellipse, conchoid of Nicomedes, limaçon of Pascal, spiral of Archimedes, quadratrix, cissoid, cycloid, companion to the cycloid, and the parabola of Descartes.

Newton and Leibnitz.

We thus see that both in England and on the Continent the principles of the infinitesimal calculus were being gradually developed. Their importance was seen and understood, and they were employed in extending the dominion of geometry. Nothing more was required but an appropriate notation to form them into a system. This was accomplished by Newton and Leibnitz, who appeared nearly at the same time in the field of discovery. In ascribing to each of these great men the full honor due to the merit of the invention of the calculus, it is proper to add that this is a question which at one time divided the opinions of the scientific world, and gave rise to a controversy which was agitated with great keenness for almost a whole century. There never could be any doubt as to Newton being the inventor of the calculus of fluxions; but the question strongly contested has been, whether Leibnitz invented his calculus independently, or borrowed it from the fluxional calculus, with which at bottom it is identical.

---

[1] Fermat was in possession of his method in the year 1629, as appears from a statement in one of his letters to Roberval, although it was not made public until this correspondence was printed by M. Herigone in his *Cursus Mathematicus* (1644).

Leibnitz, born in 1646, four years after Newton, was also later than Newton in beginning his career of discovery in mathematics. In 1673, being in London, he communicated to some members of the Royal Society what he supposed to be discoveries relative to the differences of numbers. It was, however, shown to him that the same subject had been previously discussed by Mouton, a French geometer. He then appears for the first time to have turned his attention to infinite series. On his return to Germany in 1674 he announced to Mr. Oldenburg, secretary to the Royal Society, that he possessed very general analytical methods, depending on infinite series, by which he had found theorems of great importance relating to the quadrature of the circle. In reply Oldenburg informed him that Newton and Gregory had discovered similar methods for the quadrature of curves, which extended to the circle.

On June 13, 1676, Newton addressed a letter to Oldenburg, for transmission to Leibnitz. It contained his binomial theorem, the now well-known expressions for the expansion of an arc in terms of its sine, and the converse, that of the sine in terms of the arc. Contrary to modern procedure, he deduced the latter from the former, by the method of reversion of series,—a method called by Newton the "extraction of roots." This letter also contained an expression in an infinite series for the arc of an ellipse, and various other results, accompanied, however, only by brief indications of his method of demonstration.

On the 27th of the following August, Leibnitz sent a reply through Oldenburg, in which he requested fuller explanation from Newton of his theorems and method of demonstration. Leibnitz added that he possessed another method of extensive application in geometry and mechanics, of which he gave some examples.

To this communication Newton replied on October 24, 1676, in a letter which occupies thirty pages in Newton's *Opuscula* (ed. Cast.). As this letter probably gives a more complete account of the order and dates of Newton's discoveries than is to be obtained elsewhere, it appears desirable to give a brief abstract of it here. He commences by commending the very elegant method of Leibnitz for the treatment of series. He goes on to state that he himself had three methods of such treatment. His first was arrived at from the study of the method of interpolation of series by which Wallis had arrived at expressions for the area of the circle and hyperbola. Thus, by considering the series of expressions $(1-x^2)^{\frac{0}{2}}$, $(1-x^2)^{\frac{1}{2}}$, $(1-x^2)^{\frac{2}{2}}$, $(1-x^2)^{\frac{3}{2}}$, $(1-x^2)^{\frac{4}{2}}$, etc., he deduced from the known values of the alternate expressions, by the method of interpolations, the law which connects the successive coefficients in the expansions of the intermediate terms $(1-x^2)^{\frac{1}{2}}$, $(1-x^2)^{\frac{3}{2}}$, $(1-x^2)^{\frac{5}{2}}$, etc. Newton thus determined the area of the circle and hyperbola, in infinite series. He adds that this method would have completely escaped his memory if he had not a few weeks previously found the notes he had formerly made on the subject.

By following out the idea thus suggested, he was led to the discovery of his binomial expansion. This he tested in the case of $(1-x^2)^{\frac{1}{2}}$ by the algebraic process of extracting the square root,—as also, in other cases, by direct multiplication. Having established this result, he was enabled to discard the method of interpolation, and to employ his binomial theorem as the most direct method of obtaining the areas and arcs of curves. Newton styled this his second method. He states that he had discovered it before the plague (in 1665–66) had compelled him to leave Cambridge, when he turned his attention to other subjects. He goes on to say that he had ceased to pursue these ideas as he suspected that Nicholas Mercator had employed some of them in his *Logarithmotechnia* (1668); and this led him to think that the remainder would have been found out before he himself was of sufficiently ripe age to publish[1] his discoveries (*priusquam ego ætatis essem maturæ ad scribendum*).

Newton proceeds to state that about 1669 he communicated through Barrow to Collins a compendium of his method subsequently called the "method of fluxions," with applications to areas, rectification, cubature, etc. In his letter, however, he gave no explanation of this method, carefully concealing its nature in an anagram of transposed letters, thus—6*a cc d æ* 13*e ff* 7*i* 3*l* 9*n* 4*o* 4*q rr* 4*s* 9*t* 12*v x*.[2]

At the end of his letter Newton alludes to the solution of the "inverse problem of tangents," a subject referred to in Leibnitz's letter. For the solution of such problems he says he has two methods, which also he disguises under an anagram. The meaning of this anagram is given in his *Opuscula*, and, as it throws light on Newton's method of discovery, it is introduced here:—"Una methodus consistit in extractione fluentis quantitatis ex æquatione simul involvente fluxionem ejus. Altera tantum in assumptione seriei pro quantitate qualibet incognita ex qua cætera commode derivari possunt, et in collatione terminorum homologorum æquationis resultantis, ad eruendos terminos assumptæ seriei."

On June 21, 1677, Leibnitz sent a reply to Newton, through Oldenburg. In this he explained his method of drawing tangents to curves, introducing his notation, dx and dy, for the infinitely small differences of the successive co-ordinates of a point on the curve, and showed that his method could be readily applied if the equation contained irrational functions. Further on he gave one or two examples of the inverse method of tangents, such as to find the curve whose subtangent is $b+cy+dy^2-x$. This, which is a problem involving the integration of a differential equation of the first order, shows that Leibnitz was then in possession of the principles of the integral calculus. The sign of integration has been found to have been employed by him in a manuscript of 29th October, 1675, preserved in the royal library of Hanover (Gerhardt, *Die Entdeckung der höheren Analysis*, 1855). This date is of importance, as it proves conclusively that Leibnitz was in possession of his method before he had received through Oldenburg any account of Newton's method of fluxions, and thus shows how unfounded was the statement made in the *Commercium Epistolicum* that Leibnitz had borrowed his calculus from Newton.

The death of Oldenburg, which took place shortly afterwards, put an end to this correspondence. In the year 1684 Leibnitz, for the first time, made his method public, in the *Acta Eruditorum* of Leipsic, under the following title, "Nova methodus pro maximis et minimis, itemque tangentibus, quæ nec fractas nec irrationales quantitates moratur, et singulare pro illis calculi genus." Newton's method did not appear until 1687, when he published it, in a geometrical form, as the method of prime and ultimate ratios, in his great work *Philosophiæ Naturalis Principia Mathematica*; consequently, while Newton's claim to the priority of discovery is now admitted by all, it is no less certain that Leibnitz was the first to publish his method. It is also certain that Leibnitz enjoyed unchallenged for fifteen years the honor of being the inventor of his calculus; even Newton himself rendered him that justice in the first two editions of his *Principia*.

---

[1] Newton also states in this letter that, in consequence of the various objections, etc., which were raised to his theory of light and color, he felt that he had been imprudent in having published it, because by catching at the shadow he had lost the substance, namely, his own quiet and repose. This probably may have been the reason why Newton refrained for so long a time from making public his discovery of the method of fluxions, notwithstanding the earnest solicitation of his friends.

[2] It means *Data æquatione quotcunque fluentes quantitates involvente, fluxiones invenire; et vice versa.*

Subsequently, however, a foreigner, Fatio de Duillier, piqued, as is abundantly manifested in his tract, at having been omitted in an enumeration by Leibnitz of eminent geometers alone capable of solving John Bernoulli's celebrated problem of the line of quickest descent, published in 1699, at London, a memoir on the problem. In this he declared that he was obliged by the undeniable evidence of things to acknowledge Newton, not only as the first, but as by many years the first inventor of the calculus, from whom, whether Leibnitz, the second inventor, borrowed anything or not, he would rather they who had seen Newton's letters and other manuscripts should judge than himself.

This insinuation drew forth an animated reply from Leibnitz, in the *Acta Eruditorum*, May, 1700, in which he cited Newton's letters, as also the testimony which Newton had rendered to him in the *Principia*, as proof of his claim to an independent authorship of his method. A reply was sent by Duillier which the editors of the *Acta Eruditorum* refused to publish (*quasi lites aversati*). Here the dispute rested for a time. It was revived in the year 1705, when, on the publication of Newton's *Tractatus de Quadratura Curvarum*, an unfavorable review of the work—written by Leibnitz, as has since been established—appeared in the *Acta Eruditorum*. In this review, among other observations, it was stated that Newton employed and had always employed fluxions instead of the differences of Leibnitz, just as Fabri had substituted, in his synopsis of geometry, motion instead of the indivisibles of Cavalieri. This statement excited great indignation among British mathematicians, one of whom—Keill, Savilian professor of astronomy at Oxford—in a letter printed in the *Philosophical Transactions* of 1708, affirmed that Newton was, without doubt, the first inventor of the calculus, and that Leibnitz, in the *Acta Eruditorum*, had merely changed the name and the notation. Leibnitz, thus directly charged with having taken his calculus from Newton, addressed a letter, March, 1711, to Mr. (afterwards Sir Hans) Sloane, the secretary of the Royal Society, in which he reminded him that, a similar accusation having been made some years previously by M. Fatio de Duillier, the society and Newton himself had disapproved of it, and he requested the society to require that Keill should retract his accusation. This Keill refused to do, and in answer addressed a letter of great length to Sloane, in which he professed to show, not only that Newton had preceded Leibnitz in the invention, but that he had given Leibnitz so many indications of his calculus that its nature might have been easily understood by any man of ordinary intelligence. That this was in substance the statement of Newton himself appears from the minutes of the Royal Society (of which he was president), April 5, 1711, in which it is stated "that the president gave a short account of the matter, referring to some letters, published by Dr. Wallis, upon which Mr. Keill was desired to draw up an account of the matter under dispute and set it in a just light." Keill accordingly wrote a letter which was submitted to the society on May 24.

This letter was forwarded to Leibnitz, who, on December 29, 1711, addressed a second letter to Sloane, requiring the society to stop these unjust attacks of Keill, and saying that Keill was too young a man to know what had passed between Newton and himself. In conclusion, he submitted the matter to the equity of the Royal Society, and stated that he was persuaded that Newton himself would do him justice. The Society, thus appealed to, appointed a committee on 6th of March, 1712, to examine the old letters and other documents which had passed between mathematicians on the subject and to furnish a report to the Society. The members of the committee, as originally appointed, were Arbuthnot, Hill, Halley, Jones, Machin, and Burnet. To these Robarts, a contributor to the *Transactions*, was added on the 20th; Bonet, the Prussian minister, on the 27th, and De Moivre, Aston, and Brook Taylor on the 17th of April. The complete list of the committee was not made public until the question was investigated by the late Professor De Morgan, in 1852.

Their report, made on April 24, 1712, concluded as follows: "The *differential method* is one and the same with the *method of fluxions*, excepting the name and mode of notation; Mr. Leibnitz calling those quantities *differences* which Mr. Newton calls *moments* or *fluxions*, and marking them with the letter *d*, a mark not used by Mr. Newton. And therefore we take the proper question to be, not who invented this or that method, but who was the first inventor of the method; and we believe that those who have reputed Mr. Leibnitz the first inventor knew little or nothing of his correspondence with Mr. Collins and Mr. Oldenburg long before; nor of Mr. Newton's having that method above fifteen years before Mr. Leibnitz began to publish it in the *Acta Eruditorum* of Leipsic. For which reasons we reckon Mr. Newton the first inventor, and are of opinion that Mr. Keill, in asserting the same, has been no ways injurious to Mr. Leibnitz." On the same day the Society ordered the collection of letters and manuscripts, together with the report of the committee, to be printed, along with any other matter which would throw light on the question. This was accordingly done in the course of that year under the title *Commercium Epistolicum D. Johannis Collins et aliorum de analysi promota jussu Societatis Regiæ in lucem editum*, but not at first for general publication, the few copies printed being distributed as presents. In 1715 an elaborate account of the contents of this report was published by order of the Royal Society in their *Transactions*. The manuscript of almost the whole of this account has in recent years been found in Newton's own handwriting. (Brewster's *Life of Newton*, vol. ii. p. 75.)

In 1722 what is usually considered the second edition was published. The latest and most important edition is that of M. Biot and M. Lefort, published in Paris in 1856, in which many additional letters and documents necessary for an impartial appreciation of the question are added.

It would occupy too large a share of our space to detail the long and bitter controversy to which the *Commercium Epistolicum* gave rise. It suffices to state that from the time of its publication until long after the death of Leibnitz[1] (November 14, 1716), and of Newton (March 28, 1727), this controversy was carried on, first between Newton and Leibnitz, and afterwards by their respective admirers. The feeling which induces men to exalt their own nation at the expense of their neighbors contributed immensely to increase the bitterness of the dispute. It is the less necessary nowadays to enter into the merits of this great quarrel, inasmuch as it has long been agreed on, by all mathematicians who have examined into the controversy, that Newton and Leibnitz are both justly entitled to be regarded as independent discoverers of the principles of the calculus, and that, while Newton was certainly master of the method of fluxions before Leibnitz discovered his method, yet Leibnitz had several years priority of publication.

The dispute seems, however, to have had a very injurious effect on the progress of mathematics in England; for, partly owing to the natural veneration for the lofty genius of Newton, but mainly, it would appear, in consequence of the strong national prejudice produced by the bitterness of the above-mentioned controversy, British mathematicians, for considerably more than a century, failed to perceive the great superiority of the notation originated by Leibnitz to that which Newton introduced. And thus, while the Bernoullis, Euler, D'Alembert, Clairaut, Lagrange, Laplace, Legendre, and a number of other eminent Continental mathematicians were rapidly extending knowledge, by employing the infinitesimal calculus in all branches of mathematics, pure and applied, and producing a number of great treatises in every department, in England comparatively little progress was made.

---

[1] That Leibnitz at the time of his death was occupied with a reply justifying his title to an independent discovery of the calculus, has been brought to light in recent years by Dr. Gerhardt's publication (1846) of the manuscript entitled *Historia et Origo Calculi Differentialis a G. G. Leibnitio*. In his letter from Vienna, 25th August, 1714, to Chamberlayne, Leibnitz expressed his purpose, on his return to Hanover, to publish an impartial *Commercium Epistolicum*. This, however, remained for others to accomplish.

In fact it was not until 1815—when three Cambridge graduates, who each afterwards rose to great distinction, Sir John Herschel, Babbage, and Peacock, published a translation of Lacroix's smaller treatise on the calculus—that the algorithm universally adopted by Continental writers was introduced into the studies of the British universities. The great superiority of Leibnitz's system of notation was soon acknowledged, and thus an immense impetus given to the study of mathematics, in all its branches. Ever since that time the method of fluxions,[1] as a distinct method, has become almost obsolete; and it is now strange to read Newton's own assertion in the preface to the *Commercium Epistolicum*, in which he claims that the method of fluxions is more elegant, more natural, more geometrical, more useful, more certain, and incomparably more universal, than that of Leibnitz.

We next proceed to give a brief account of the notation and principles of the method of fluxions, as that which was first discovered.

The idea of a fluxion, as its name indicates, originated from that of motion, and all geometrical magnitudes were considered by Newton as capable of generation by continuous motion. Thus lines are conceived as generated by the motion of points, surfaces by that of lines, solids by surfaces, etc. Again, if we conceive a moving point as describing a curve, and the curve referred to co-ordinate axes, then the velocity of the moving point can be decomposed into two others, one parallel to the axis of x, the other to that of y; these velocities are called the "fluxions" of x and y respectively, and the velocity of the point is the fluxion of the arc. Reciprocally, the arc is called the "fluent" of the velocity with which it is described; and the ordinates x and y are the fluents of their velocities respectively. Again, if the velocity of the moving point be regarded as constant, the fluxions of the abscissa and ordinate of any point on the curve (except in the case of a right line) will be variable; and their ratio at each instant will depend on the nature of the curve, *i. e.*, on the relation between the co-ordinates. Reciprocally, the relation between the co-ordinates depends necessarily on that which exists at each instant between their fluxions. Hence we may seek to determine the relation between the fluxions, when we know that which exists between the co-ordinates, *i. e.*, the equation of the curve; and reciprocally we may seek to discover the relation between the co-ordinates when we know that between their fluxions, either alone or combined with the co-ordinates themselves. The first part of the problem is called the "method of fluxions," and the second the "inverse method of fluxions."

Again, in the same case, not only do the co-ordinates x and y change, but also the subtangent, normal, radius of curvature, etc.; that is to say, each of these quantities increases or decreases more or less rapidly, as well as the co-ordinates themselves. All these quantities, accordingly, have fluxions, whose ratios are also determined by the motion of the point. Consequently these quantities may in like manner be regarded as "fluents." Similar remarks apply to areas and surfaces regarded as fluents. Newton observes that he does not consider the time formally (*formaliter*), but supposes that one of the proposed quantities increases equably (*æquabili fluxu*), to which the others are referred (*tanquam ad tempus*). This fluent may be chosen at pleasure, and is what we now are accustomed to call the independent variable.

Again, if any quantities, regarded as fluents, be represented by letters, such as u, x, y, z, etc., the corresponding fluxions are represented by $\dot{u}$, $\dot{x}$, $\dot{y}$, $\dot{z}$, etc., respectively. Next, if $\dot{u}$, $\dot{x}$, $\dot{y}$, $\dot{z}$ be regarded as variable or fluent quantities, their fluxions are represented by $\ddot{u}$, $\ddot{x}$, $\ddot{y}$, $\ddot{z}$, and are the fluxions of the fluxions of u, x, y, etc., *i. e.*, the second fluxions. If one of these, x for instance, be taken as the "principal fluxion," then $\dot{x}$ is a constant, and consequently $\ddot{x}=0$. In like manner we may have third fluxions, as well as those of higher orders.

Again, u, x, y, etc., may be regarded as themselves the fluxions of other quantities called their fluents. These quantities were represented by Newton, sometimes by u', x', y', etc., in other places by $[u]$, $[x]$, etc.; and from them it may be desired to proceed to the fluents.

Newton remarks that this second general problem involves three cases:—(1) when the equation contains the fluxions of two quantities and but one of their fluents; (2) when the equation involves both the fluents as well as both the fluxions; (3) when the equation contains the fluents and the fluxions of three or more quantities.

The problem of finding the fluent when the fluxion is known is the simplest case of the first class, and is the same as the method of integration of Leibnitz. It was usually styled in Newton's time the method of quadratures, for it is reducible to the problem of finding the area of a curve, since it can be easily seen that the fluxion of an area is the ordinate, when the abscissa is taken as the principal fluent. The second class comes under what is now called the solution of differential equations; this was styled in Newton's time the "inverse method of tangents." Newton's third class is now treated of under the solution of "partial differential equations."

The infinitely small parts by which the variable quantities increase in an indefinitely small time were called by Newton the "moments" of the fluent quantities; thus, he represented an infinitely small portion of time, called a moment, by o; then the moments or infinitely small increments of u, x, y, etc., are represented by $\dot{u}o$, $\dot{x}o$, $\dot{y}o$, etc.; so that if u, x, y, etc., denote the values of the fluents at any instant, their values at the end of an indefinitely small interval of time are represented by $u+uo$, $x+\dot{x}o$, etc.

For instance, let the fluents x, y, be connected by the equation

$$x^3-ax^2+axy-y^3=0;$$

then, substituting $x+\dot{x}o$ for x, and $y+\dot{y}o$ for y, subtracting the original equation, and dividing by o, we get

$$3x^2\dot{x}-2ax\dot{x}+ay\dot{x}+ax\dot{y}-3y^2\dot{y}+3x\dot{x}^2o+\text{etc.}$$

Hence, regarding o as an evanescent quantity, we obtain, neglecting the powers of o,

$$3x^2\dot{x}-2ax\dot{x}+ay\dot{x}+ax\dot{y}-3y^2\dot{y}=0;$$

consequently $x:\dot{y}=3y^2-ax:3x^2-2ax+ay.$

This, as Newton observes, furnishes a ready method of drawing the tangent at any point on a curve. In fact, it is, changing the notation, equivalent to Barrow's method already considered. Newton adds, that in like manner we may neglect, in all cases, the terms multiplied by the second and higher powers of o, and thus find an equation between x, y and their fluxions $\dot{x}$, $\dot{y}$.

A good deal of confusion has arisen from the word fluxion having been commonly employed by the early English writers in the sense of an infinitely small increment. Thus, as is abundantly shown by Professor De Morgan in his tract on the early history of infinitesimals in England (*Phil. Mag.*, 1852), all the early writers on fluxions, up to 1704, except Newton and Cheyne, employed the notation $\dot{x}$ to represent an infinitely small increment, calling it a fluxion. It is even remarkable that, in the extract from the *Commercium Epistolicum* which we have given, the words moment and fluxion seem to have been employed as synonymous. It should also be observed that in Newton's earliest papers his method is strictly infinitesimal; and in the first edition of his *Principia* (1687) the description of fluxions is founded on infinitely small increments; so that the original conception of the calculus in England, as well as on the Continent, was based on infinitesimal principles.

---

[1] That the fluxional notation in combination with that of differentials has its advantages is exhibited in many physical works; we may instance Thomson and Tait's *Treatise on Natural Philosophy*.

Objection has frequently been made to Newton's method of fluxions, that it introduced a foreign idea, namely, that of motion, into geometry and analysis. This objection is scarcely well founded, and was indeed answered by Newton when he stated that all his method contemplates is that one of the variables should increase uniformly (*æquabili fluxu*) as we conceive time to do.

Leibnitz, like Newton, supposed any variable magnitude as continually increasing or diminishing, by momentary increments or decrements. These instantaneous changes he regarded as infinitely small differences. Thus the infinitely small difference of a variable u was represented by du. His calculus also, like Newton's, had two parts:—(1) the *differential calculus*, which investigated the rules for deducing the relation between these infinitely small differences of quantities from the relation which exists between the quantities themselves; (2) the *integral calculus*, which treated of the inverse problem, viz., the determination of the relation of the quantities when that of their differences is known. This corresponds to Newton's inverse method of fluxions, as the differential calculus does to his direct method. It is not necessary to go into further detail here on Leibnitz's method, as it will be more fully considered subsequently; in fact, all our treatment of the calculus will be merely a development of this method.

Objectors.

The infinitesimal calculus had in the outset its opponents, such as the Abbé de Catelan, a zealous Cartesian, who declared in his *Logistique Universelle et Méthode pour les Tangentes* (1694), that it would be better to extend the principles of the Cartesian geometry than to seek for new methods; and this was said in the preface of a book composed on the principles, somewhat disguised, of the very calculus of which he was an opponent. It had another adversary in Nieuwentijt, a man who had written some tolerable works on morality and religion, but who had slight pretensions to be regarded as a geometer. Catelan was satisfactorily answered by De l'Hôpital, as was Nieuwentijt by Leibnitz, and afterwards by Bernoulli and Hermann, who proved that this adversary of the calculus really did not know what he opposed. For instance, Nieuwentijt, while admitting differentials of the first order, rejected all those of higher orders. For such a difference of treatment there is no foundation, for, if we imagine in a circle an infinitely small chord of the first order, the versine is an infinitely small line of the second order.

The calculus had a more formidable enemy in Rolle, a skilful algebraist, but a man full of confidence in his own notions, rash in forming his opinions, and jealous of the inventions of others. He attacked the certainty of its principles, and attempted to show that its conclusions were at variance with those obtained by methods previously known, which were acknowledged to be correct. His attack was repelled by Varignon, who completely obviated the objections to the truth of the principles. These disputes occupied the French Academy a considerable part of the year 1701. The members were chiefly mathematicians advanced in years, who had been long accustomed to other methods, and were therefore not much disposed to receive new doctrines. Some took no part in the dispute, yet were not sorry to perceive a storm raised against a theory for which they had no great liking; others, more under the influence of their passions and prejudices, declared open war against it. Rolle brought forward objection upon objection; and although Varignon answered them in succession, yet the former always claimed the victory. In the end the dispute degenerated into a quarrel, and commissioners were appointed to decide on it. These were Gouye, Cassini, and De la Hire. They, however, pronounced no judgment; but the public opinion, or at least the opinion of geometers, was in favor of Varignon. The first controversy thus ended, or rather was suspended for want of a decision from the commission; but Rolle soon renewed hostilities. The defence was next taken up by Saurin. The ground of attack was the indefinite form which the calculus gives for the subtangent of a curve at a point where two branches intersect each other, and which in this case is expressed by the fraction $\frac{0}{0}$. Saurin's answer was satisfactory; but Rolle, intrenched in masses of calculation, obstinately maintained the combat. The Academy was again appealed to in 1705. The Abbé Bignon, who conducted its affairs, undertook to decide the controversy, with the assistance of Gallois and De la Hire, two judges by no means favorable to Saurin. They gave no absolute judgment, but recommended Rolle to conform more strictly to the rules of the Academy, and Saurin to forgive the proceedings of his adversary. Rolle afterwards did justice to the calculus by acknowledging his error in opposing it, and admitted that he had been urged forward by malevolent persons, one of whom was the Abbé Gallois.

Mathematicians have differed as to the best way of expounding the principles of the calculus. Newton, as has already been stated, employed the theory of motion as the means of connecting its doctrines with the principles of ordinary analysis. Leibnitz, again, with the same view, conceived quantity as passing from one degree of magnitude to another by the continual addition of infinitely small parts. The mind finds no great difficulty in distinctly apprehending the subject in either way. Objections have, however, been taken to both, and attempts made to substitute a better. Euler considered the infinitely small quantities of Leibnitz as absolutely zeros, that have to each other ratios derived from those of the vanishing quantities which they replace. D'Alembert proposed to make the basis of the calculus the consideration of the ratios of the limits of quantities. This method, as was indeed stated by D'Alembert, does not differ in any material respect from Newton's prime and ultimate ratios. An English mathematician, Landen, substituted for the Newtonian method of fluxions another purely algebraical. His views are contained in a work entitled *The Residual Analysis, a new branch of the Algebraic Art* (1764).

Lagrange.

Lagrange, too, in the *Memoirs of the Berlin Academy* for 1772, proposed to base the calculus altogether on the expansion of functions, and thus to establish it on algebraical principles merely. He subsequently developed his method in his *Théorie des Fonctions Analytiques* (1797), and in his *Leçons sur le Calcul des Fonctions* (1806). Lagrange, however, adopted the infinitesimal method as the basis of his most important work, viz., the *Mécanique Analytique.* He states in his preface to its second edition (1811) that "when we have properly conceived the spirit of the infinitesimal method, and are convinced of the exactness of its results by the geometrical method of prime and ultimate ratios, or by the analytical method of derived functions, we may employ infinitely small quantities as a sure and valuable means of abridging and simplifying our demonstrations."

We shall close this introduction with a list of works on the subject.

Principal works bearing on the Infinitesimal Method before the Invention of the Calculus.—Kepler, *Nova Stereometria Doliorum Vinariorum,* 1615; Cavalieri, *Geometria Indivisibilium,* 1635; Id., *Exercitationes Geometricæ Sex,* 1647; Descartes, *Géométrie,* 1637; Torricelli, *De Sphæra et Solidis Sphæralibus,* 1644; Grégoire St. Vincent, *De Quadratura*

Circuli, 1647; Huygens, *Theoremata de Quadratura*, 1647; Id., *Horologium Oscillatorium*, 1673; Wallis, *Arithmetica Infinitorum*, 1655; Id., *Opera Mathematica*, 3 vols., 1693–99; Fermat, *Opera Varia Mathematica*, 1679; Mercator, *Logarithmotechnia*, 1668; James Gregory, *Vera Circuli et Hyperbolæ Quadratura*, 1668; Barrow, *Lectiones Geometricæ*, 1670; Slusius, "Tangents to all Geometrical Curves," *Phil. Trans.*, 1672; Wren, "Rectification of the Cycloid," *Phil. Trans.*, 1673; Bullialdus, *Arithmetica Infinitorum*, 1682.

List of some of the Principal Works on the Calculus.—Newton, *De Analysi per Æquationes numero terminorum infinitas*, circulated in MS. in 1669 (extracts from this memoir appeared in the 2d vol. of Wallis's works, 1693, which comprehends the first publication to the world of the method of fluxions); Id., *Principia*, 1687; Id., *Tractatus de Quadratura Curvarum*, published with his *Optics*, 1704; Id., *Methodis Differentialis*, 1711; Leibnitz, "Nova Methodus pro maximis et minimis, itemque tangentibus," *Acta Erud.*, 1684; Leibnitz et Bernoulli, *Commer. Epis. Ph. et Math.*, 1745; John Bernoulli, "Inventio Lineæ Brachistochronæ," *Acta Erud.*, 1696; Id., *Analysis Problematis Isoperimetrici*, 1697; Id., *Opera Omnia*, 1742; James Bernoulli, *Opera*, 1744; De l'Hôpital, *Analyse des Infiniment Petits*, 1696; Cheyne, *Fluxionum Methodus Inversa*, 1703; Hayes, *Treatise on Fluxions*, 1704; Manfredi, *De Construc. Æquat. Diff. Primi Gradus*, 1707; Taylor, *Methodus Incrementorum*, 1715; Stirling, *Lin. Tert. Ordin. Newtoni*, 1717; Hermann, "De Construc. Equat. Diff.," *Comm. Petrop.*, 1726; Fontenelle, *Élémens de la Géométrie de l'Infini*, 1727; Clairaut, "Determinatio Curvæ ejusdem Diff.," *Acta Erud.*, 1729; De Moivre, *Miscellanea Analytica*, 1730; Hodgson, *Fluxions*, 1736; Simpson, *Fluxions*, 1737; Maclaurin, *Fluxions*, 1742; Donna Agnesi, *Instituzioni Analitiche*, 1748; Euler, *Meth. inven. Lin. Curv. max. vel. min. prop. gaud.*, 1744; Id., *Introd. Analy. Infin.*, 2 vols., 1748; Id., *Institut. Cal. Diff.*, 2 vols. 1755; Id., *Institut. Cal. Integ.*, 3 vols., 1768–70 (the titles of Euler's numerous memoirs on the Differential and Integral Calculus are given in the edition of his *Differential Calculus* published at Pavia in 1787); Walmesly, *Analyse des Mésures, des Rapports, et des Angles*, 1750; Stirling, *Methodus Differentialis*, 1753; Bougainville, *Traité du Calcul Intégral*, 1754; Landen, *Mathematical Lucubrations*, 1755; Id., *Residual Analysis*, 1764; Id., *Mathematical Memoirs*, 1780; Saunderson, *Method of Fluxions*, 1756; Kästner, *Separatio Indeterminat. in Æquat. Diff.*, 1756; D'Alembert, *Opuscules Mathématiques*, 1761–80; Robins, *Mathematical Tracts*, 1761; Waring, *Miscellanea Analytica*, 1762; Id., *Meditationes Analyticæ*, 1776; Condorcet, *Du Calcul Intégral*, 1765; Le Seur et Jacquier, *Élémens du Calcul Intégral*, 1768; Lexell, "Methodus Integrandi Æq. Diff.," *Comm. Petrop.*, 1769; Fontaine, *Traité du Calcul Diff. et Intégral*, 1770; Gianella, *De Fluxionibus et earum Usu*, 1771; Cousin, *Traité du Calcul Différentiel et Intégral*, 1776; Laplace, "L'Usage du Calcul. aux Diff. part.," *Mém. de l'Acad.*, 1777; Condorcet, "De Integ. cujusdam Æquationis," *Comm. de Bonon.*, 1783; Paoli, *Memoria sull' equazione a differenze finite e parziali*, 1784; Monge, "Sur le Cal. Int. des Equat. aux Diff. part.," *Mém. de l'Acad.*, 1784; Charles, "Recherches sur le Calcul Intégral," *Mém. de l'Acad.*, 1784; L'Huillier, *Exposition des Principes des Calculs Supérieurs*, 1786; Id., *Princip. Calculi Diff. et Integ.*, 1795; Mascheroni, *Annotationes ad Cal. Integ. Euleri*, 1790; Tabiescen, *Principia atque Historia Calculi Diff. et Integ. necnon Methodi Fluxionum*, 1793; Lagrange, "Calcul des Variations," *Misc. Taur.*, vols. ii. and iv., 1760–69; Id., *Théorie des Fonctions Analytiques*, 1797; Id., *Leçons sur le Calcul des Fonctions*, 2d ed., 1806; Id., separate *Memoirs*, edited under the care of Serret, 7 vols., 1867–77 (the remainder of his works are in course of republication in the same series); Vince, *Principles of Fluxions*, 1797; Carnot, *Réflexions sur la Métaphysique du Calcul Infinitésimal*, 1797; Lacroix, *Traité du Calcul Différentiel et du Calcul Intégral*, 1797; Arbogast, *Calcul des dérivations*, 1800; Legendre, *Exercices de Calcul Intégral*, 3 vols., 1811–19; Id., *Traité des Fonctions Elliptiques*, 3 vols., 1825–28; Cauchy, *Cours d'Analyse*, 1821; Id., *Appl. Géom. du Cal. Infin.*, 1823; Id., *Mém. sur les int. déf. prises entre des limites imag.*, 1825; Id., *Leçons sur le Calcul Différentiel*, 1829; Ohm, M., *System der Mathematik*, 9 vols., 1822–52; Id., *Lehrbuch f. d. gesammte Höh. Math.*, 2 vols., 1839; Magnus, *Sammlung von Aufgaben d. Analyt. Geom.*, 1833; Navier, *Leçons d'Analyse de l'Éc. Polyt.*, 1840; Moigno, *Leçons de Cal. Diff. et de Cal. Int.*, 2 vols., 1840–44; Id., *Calcul des Variations*, 1861; Duhamel, *Cours d'Analyse de l'Éc. Polyt.*, 2 vols., 1840–41; 3d ed. by Bertrand, 2 vols., 1874–75; Cournot, *Théorie des Fonctions et du Calcul Infinitésimal*, 1841; Gregory, *Examples on the Diff. and Int. Calculus*, 1841; De Morgan, *Differential and Integral Calculus*, 1842; Hymers, *Integral Calculus*, 1844; Schlömilch, *Handbuch der Differenzial- und Integralrechnung*, 1847; Id., *Compendium der Höheren Analysis*, 2 vols., 1874; Minding, *Sammlung von Integraltafeln*, 1849; Meyer, *Exposé Élém. de la Théorie des Int. Déf.*, 1851; Todhunter, *Differential and Integral Calculus*, 2 vols., 1852; Id., *On Functions of Laplace, Lamé, and Bessel*, 1875; Price, *Infinitesimal Calculus*, 2 vols., 1854; Bierens De Haan, *Tables d'intégrales définies*, 1858; Id., *Exposé de la théorie des intégrales définies*, 1862; Boole, *Differential Equations*, 1859; Id., *Calculus of Finite Differences*, 1860; Grassmann, *Die Ausdehnungslehre*, 1862; Bertrand, *Traité de Cal. Diff. et de Cal. Int.*, 2 vols., 1864–70; Meyer, G. F., *Vorles ü. d. Theorie d. bestimmten Integrale*, 1871; Williamson, *Differential and Integral Calculus*, 1872–74; Hermite, *Cours d'Analyse*, 1873; Durége, *Theorie d. Funktionen einer complexen veränderl. Grösse*, 2d ed., 1873; Folkierski, *Principles of Diff. and Int. Calc.* (Polish), Paris, 2 vols., 1873; Rubini, *Elementi di Calcolo infinitesimale*, 2 vols., 1874–75; Serret, *Cours de Calc. Diff. et Int.*, 2d ed., 2 vols., 1878–79 (the 8th edition of Lacroix's *Traité Élémentaire*, by Serret, and Hermite, contains in the notes many valuable additions); Riemann, *Gesam. Math. Werke*, 2d ed., 1876; Id., *Partielle Differentialgleichungen*, 2d ed., 1876; Lipschitz, *Lehrbuch der Analysis*, 2 vols., 1877–80; Hoüel, *Cours de Calcul Infinitésimal*, 3 vols., 1878–79; Boucharlat, *Él. de Calc. Diff. et Int.*, 8th ed. by Laurent, 1879; Stegemann, *Differential- und Integralrechnung*, 2 vols., 3d ed., 1880.

The preceding list contains the names of some of the most important existing treatises on the calculus. It makes no pretence to completeness; in fact many of the most valuable contributions to the subject are published in the numerous mathematical journals, and in the transactions of learned societies. In treating of elliptic and hyperelliptic functions we shall give a short list of the chief works on that great branch of the calculus.

PART I.

Differential Calculus.

1. In the application of algebra to the theory of curves and surfaces some of the quantities under consideration are conceived as having always the same magnitude, such as the radius of a given circle or of a given sphere, or the axes of a given ellipse or hyperbola; others again are indefinite, and may have any number of particular values, such as the co-ordinates of any point on a curve. This difference naturally suggests the division of the quantities involved in any question into two kinds, one called *constants*, the other *variables*.

It is usual in analysis to denote constants by the first letters of the alphabet, a, b, c, etc.; variables by the last, u, v, w, x, y, z, etc.

2. One quantity is said to be a *function* of another when they are so related that any change made in the one causes a corresponding variation in the other. This relation may subsist whether there exist an expression for the function by which its value is determined for each value of its *argument*; or the relation may sometimes be defined by certain characteristics of continuity and discontinuity. When an *expression* is presupposed the relation is usually represented by the letters F, f, ϕ, etc. Thus the equations

$$u = F(x), \qquad v = f(x), \qquad w = \phi(x),$$

denote that u, v, w are regarded as functions of x, whose values are determined for any particular value of x when the forms of the functions are known.

In each of these expressions the argument x is regarded as the *independent* variable, to which any value may be assigned at pleasure; and u, v, w are called *dependent* variables, as their values depend on that of x, and are determined when it is known.

For example, in each of the equations

$$y = 10^x, \qquad y = \tan x, \qquad y = \frac{a+x}{a-x},$$

the value of y is known when that of x is given.

Such functions are called *explicit*.

3. In many cases a variable y, instead of being given explicitly in terms of x, is connected with it by an equation of a more complicated character. For instance, suppose them connected by the relations

$$x \log y = y \log x, \ \sin y = x \sin (a+y), \ y^3 + x^3 + 3axy = 0;$$

in these cases the value or values of y may be supposed known when x is given, and y is said to be an *implicit* function of x. Such cases are comprehended in the form

$$\phi(x,y) = 0 .$$

In such a form y may be regarded as an implicit function of x, or x as an implicit function of y, at pleasure.

4. Again a quantity may be a function of two or more independent variables. Thus in the equation $u = \sin (ax + by)$, x and y may be regarded as independent variables, and u as a function of them. Such functions are in general denoted by

$$\phi(x, y), \ \phi(x, y, z), \text{ etc.}$$

5. A function $\phi(x)$ is said to be *continuous* between any limiting values of x, such as a and b, when to each value of x between those limits there corresponds a finite value of the function, and when an indefinitely small change in the value of x produces only an indefinitely small change in the function. In such cases the function in its passage from any one value to any other between the limits receives every intermediate value, and does not become infinite. This continuity can be readily illustrated by taking $\phi(x)$ as the ordinate of a curve, whose equation may then be written $y = \phi(x)$.

6. If the variable x be supposed to receive any change, such change is called an *increment;* this increment of x is usually represented by the notation Δx. A decrement is regarded as a negative increment. When the increment, or difference, is supposed to be *indefinitely small,* it is called a *differential,* and is represented by dx; *i.e.,* an infinitely small difference is called a differential.

In like manner if u be a function of x, and x become $x + \Delta x$, the corresponding value of u is denoted by $u + \Delta u$; *i.e.,* the increment of u is represented by Δu. For finite increments of x it is obvious that the ratio of the increment of u to the corresponding increment of x has, in general, a finite value. Also when the increment of x is regarded as being indefinitely small we find that the above mentioned ratio, *i.e.,* $\frac{du}{dx}$, has in general in each case a definite *limiting* value; and the first study of the differential calculus necessarily involves the investigation of such *limiting ratios* for the different forms of functions of x.

In fact we have seen that the differential calculus took its rise from the investigation of the limiting value of the ratio of the increment of the ordinate y to that of the abscissa x, so as to find the position of the tangent at any point on a curve.

Thus if the equation of a curve, referred to rectangular axes, be denoted by $f(x,y) = 0$, then $\frac{dy}{dx}$, *i.e.,* the limiting value of $\frac{\Delta y}{\Delta x}$ for any point on the curve, represents the tangent of the angle which the tangent at the point makes with the axis of x.

7. Again, if we suppose x to become $x + h$ (where h represents Δx, the increment of x) in the equation $u = f(x)$, then the increment of u is represented by $f(x+h) - f(x)$, and $\frac{\Delta u}{\Delta x} = \frac{f(x+h) - f(x)}{h}$, hence $\frac{du}{dx}$ represents the limit to which

$$\frac{f(x+h) - f(x)}{h}$$

approaches indefinitely, when h is diminished without limit.

There are two methods in general of finding this value of $\frac{du}{dx}$. The first consists in determining the limiting value of $\frac{f(x+h) - f(x)}{h}$ by decreasing h indefinitely. The second consists in expanding $f(x+h)$ in a series of ascending powers of h, and taking the coefficient of h in the expansion. This is the method introduced by Lagrange when he proposed to make the calculus a branch of ordinary algebra, and altogether independent of the consideration of infinitely small magnitudes, or of limits.

It is easily seen, as was shown by Lagrange, that the result obtained by the latter method is the same as that arrived at by the former; for, since $f(x+h)$ becomes $f(x)$ when $h = 0$, $f(x)$ is the first term in the expansion, and we may assume

$$f(x+h) = f(x) + ph + qh^2 + \text{etc.},$$

in which p, q, etc., represent functions of x, independent of h, then

$$\frac{f(x+h) - f(x)}{h} = p + qh + \text{etc.}$$

If now we suppose $h = 0$, the left hand side reduces to p; and, accordingly, the coefficient of h in the expansion of $f(x+h)$ is the limiting value of the expression

$$\frac{f(x+h) - f(x)}{h}.$$

This coefficient of h was called by Lagrange the *first derived* function of the original function $f(x)$, and he represented it by the notation $f'(x)$.

Hence we have $$\frac{du}{dx} = \frac{df(x)}{dx} = f'(x).$$

In this case $f'(x)dx$ is called the *differential* of $f(x)$, and $f'(x)$ is called its *differential coefficient.*

8. We have already seen that the principles of the calculus may be regarded either from the consideration of limits, or from that of infinitesimals or differentials; the former was the method adopted by Newton, in his later investigations at least; the latter was that adopted by Leibnitz.

The limit of a variable magnitude may be defined as follows. *If a variable magnitude tends continually to equality with a certain fixed magnitude, and approaches nearer to it than any assignable difference, however small, this fixed magnitude is called the limit of the variable magnitude.*

For example, if we suppose a polygon inscribed in or circumscribed to any closed curve, and afterwards imagine each side indefinitely diminished, then the closed curve is said to be the limit of either polygon. By this means the whole length of the curve is the limit of the perimeter of either polygon, and the area of the curve is the limit to the area of either polygon.

9. The following principles concerning limits are of frequent application. (1) The limit of the product of two quantities, which vary together, is the product of their limits. (2) The limit of the quotient of two quantities is the quotient of their limits. These are nearly self-evident propositions; they may, however, be formally proved as follows.

Let P, Q represent the variable quantities, and p, q their limits; then, if $P = p + \alpha$, and $Q = q + \beta$, α, β denote quantities which diminish indefinitely as P and Q approach their limits, and become evanescent in the limit.

Again, $$PQ = pq + p\beta + q\alpha + \alpha\beta$$

Accordingly in the limit, $PQ = pq$.

The corresponding theorem for the quotients is established easily in like manner.

10. Again, if we conceive any finite number or magnitude to be divided into a very great number of equal parts, each part is very small in comparison with the original magnitude. By supposing the number of parts to be increased indefinitely, *i.e.,* so as to exceed any assigned number, however great, then each part may be regarded as indefinitely small in comparison with the proposed magnitude, and may be called an infinitesimal with regard to it.

By an infinitesimal, or an indefinitely small magnitude, we understand a magnitude which is less than any assigned magnitude however small, and which can be diminished indefinitely, so as to approach as near as we please to zero, without ever absolutely attaining to it. For instance, the difference between the area of a circle and that of an inscribed regular polygon can, by increasing the number of sides of the polygon, be made less than any assigned area, however small; but, no matter how large the number of sides may be, this difference can never become absolutely zero. It would be easy to give other illustrations of the sense in which the word infinitesimal is employed in analysis.

11. Again, if α be regarded as an infinitesimal of the first order, α^2, being infinitely small in comparison with α, is regarded as an infinitesimal of the second order. In like manner $\alpha^3, \alpha^4, \ldots \alpha^n$, may be regarded as representing infinitesimals of the third, fourth . . . nth orders, respectively.

Again, two infinitesimals α, β are said to be of the same order if the fraction $\frac{\beta}{\alpha}$ tends to a finite limit. If $\frac{\beta}{\alpha n}$ tends to a finite limit, β is called an infinitesimal of the nth order in comparison with α.

12. To avoid misconception, it should be borne in mind that infinitesimals are not regarded as being actual quantities in the ordinary acceptation of the words, or as capable of exact representation. They are introduced for the purpose of abridgment and simplification of our reasonings, and are an ultimate phase of magnitude when it is conceived by the mind as capable of diminution below any assigned quantity, however small. Such magnitudes are in all cases, as styled by Carnot, *auxiliary quantities,* introduced for the purpose of facilitating our investigations, but they should disappear from our final results.

We shall illustrate this statement by the example of drawing a tangent to a curve,—in which problem the method of infinitesimals may be said to have originated. We introduce the infinitesimals dx and dy, for the purpose of finding their ultimate ratio, *i.e.,* in order to determine the limit of $\frac{dy}{dx}$. Now this limit is in all cases a function of x and y, the co-ordinates of the point of contact, and cannot contain in it either dx or dy, since they must be taken as evanescent quantities when we proceed to the limit.

Likewise in all other applications of infinitesimals in the differential calculus, we endeavor to find the ultimate ratio of two indefinitely small quantities, or infinitesimals;

and it is unnecessary to attach any precise meaning to such infinitesimals during the course of our investigations, further than to regard them as *variable quantities*, which become evanescent when we proceed to our final results.

In employing infinitesimals in such cases, we proceed on the principle that the limit of the ratio of two infinitesimals, α and β, is the same as that of α' and β', provided the limit of $\frac{\alpha'}{\alpha} = 1$, and limit of $\frac{\beta'}{\beta} = 1$. This is evident since, in all cases, we have

$$\frac{\alpha}{\beta} = \frac{\alpha}{\alpha'} \cdot \frac{\alpha'}{\beta'} \cdot \frac{\beta'}{\beta};$$

a result which must hold in the limit.

In consequence of this principle, before proceeding to the limit, we may neglect an infinitesimal of any order in comparison with one of a lower order. For instance, in seeking the ultimate ratio of γ to δ, where

$$\gamma = A_1\alpha + A_2\alpha^2 + A_3\alpha^3 + \text{etc.} + A_n\alpha^n + \text{etc.},$$
$$\delta = B_1\beta + B_2\beta^2 + B_3\beta^3 + \text{etc.} + B_n\beta^n + \text{etc.},$$

in which $A_1, A_2, A_3 \ldots B_1, B_2$, etc., are finite, and independent of the infinitesimals α and β, we may neglect α^2, α^3, β^2, $\beta^3 \ldots$ in comparison with α and β, and we get the limit of $\frac{\gamma}{\delta} = \frac{A_1}{B_1} \times$ limit of $\frac{\alpha}{\beta}$.

In general, if α, β be infinitesimals of the same order, their ratio has a finite magnitude; and if $\gamma = f_1(\alpha,\beta)$, $\delta = f_2(\alpha,\beta)$, then in finding the limiting value of $\frac{\gamma}{\delta}$, we take the terms of the lowest order in α and β in f_1 and f_2, neglecting all infinitesimals of higher orders; substituting in the result the limiting value of $\frac{\alpha}{\beta}$, we obtain the required limit for $\frac{\gamma}{\delta}$.

13. Again, if $\alpha_1 + \alpha_2 \ldots + \alpha_n$ represents the sum of a number of infinitely small quantities which approaches a finite limit when n is indefinitely increased, and if $\beta_1, \beta_2 \ldots \beta_n$, be another system of infinitely small quantities, such that

$$\frac{\beta_1}{\alpha_1} = 1 + \epsilon_1,\ \frac{\beta_2}{\alpha_2} = 1 + \epsilon_2,\ \ldots \frac{\beta_n}{\alpha_n} = 1 + \epsilon_n,$$

where $\epsilon_1, \epsilon_2 \ldots \epsilon_n$ become evanescent in the limit, then, when n is indefinitely increased, the limit of the sum of $\beta_1, \beta_2 \ldots \beta_n$ is equal to that of $a_1, a_2 \ldots a_n$. This is evident from the elementary algebraic principle that the ratio $\frac{\beta_1 + \beta_2 \ldots + \beta_n}{\alpha_1 + \alpha_2 \ldots + \alpha_n}$ lies between the greatest and the least values of the fractions $\frac{\beta_1}{\alpha_1}, \frac{\beta_2}{\alpha_2} \ldots \frac{\beta_n}{\alpha_n}$; and it accordingly has unity for its limit, under the supposed conditions. For example, suppose any magnitude divided into a number of parts, and that each is capable of subdivision into two parts, one of which can be simply found, and the other not so. Let $A + a$ be the first part, of which A is of the former species, and a of the latter. In like manner let $B + b$, $C + c$, etc., be the other parts. Then the required magnitude is represented by $A + B + C + \text{etc.} + a + b + c + \text{etc.}$ Now suppose that when a sufficiently great number of parts is taken we can make a, b, c, etc., as small as we please in comparison with A, B, C, etc., then $a + b + c + \text{etc.}$, can be made as small as we please with respect to $A + B + C + \text{etc.}$; consequently by continuing the process indefinitely, the limit of the sum of $A + B + C + \text{etc.}$, is equal to the required magnitude, without the necessity of paying any attention to the remaining parts. This latter may be regarded as the fundamental principle of the integral calculus, and the former, given in § 12, as that of the differential.

14. In consequence of metaphysical objections to the employment of infinitesimals, many writers on the calculus have confined themselves exclusively to the method of limits or limiting ratios, and by so doing have in many cases involved themselves in long and cumbrous demonstrations of theorems which follow with great facility by the adoption of infinitesimals. In reality the difference between the method of infinitesimals and that of limits (when exclusively adopted) is, that in the latter method it is usual to retain evanescent quantities of higher orders until the *end* of the calculation, and then to neglect them. On the other hand, such quantities are neglected from the commencement in the infinitesimal method, from the conviction that they cannot affect the final result, as they must necessarily disappear when we proceed to the limit. A very little reflexion will show that the result obtained in both cases must be the same. Moreover such quantities are neglected, not, as Leibnitz stated, because they are infinitely small in comparison with those that are retained, which would produce an infinitely small error, but because they must be neglected to obtain a rigorous result; since such result must be definite and determinate, and consequently independent of these *variable indefinitely small quantities*. It may be added that the precise principles of the infinitesimal calculus, like those of any other science, cannot be thoroughly apprehended except by those who have already studied the science, and made some progress in the application of its principles.

15. The preceding statements may also be regarded in connection with the different meanings of the terms "zero" and "an evanescent quantity." There is but one process in arithmetic which yields an *absolute* zero, namely subtraction, thus $a - a = 0$. But from no other arithmetical process does zero arise, except by the same train of ideas as leads us to the use of the word infinite. We cannot, for example, obtain the quotient zero by dividing one finite magnitude by another. We can make the result as small as we please, but not absolutely zero. When, therefore, we consider an equation made by addition or subtraction of terms, the absolute zero may be used without reservation, thus $2x + a = b$, and $2x + a - b = 0$ may be substituted for each other without any particular examination of the symbol 0. But in any other case we consider zero or 0 as the limit towards which we approach by a series of diminutions, none of which is final. Thus when we see that we can nearly arrive at a certain conclusion by attributing a small value to a particular magnitude, that we can more nearly attain this conclusion by attributing to it a smaller value, and so on without limit, *i.e.*, that we can approximate to this conclusion as nearly as we please by the use of a value as small as we please, but that we never attain it as long as the magnitude has any finite amount, then such conclusion is said, for abbreviation, to be absolutely true when the magnitude is nothing or zero. These considerations will help to explain the sense in which Euler was correct when he stated that dx and dy in the calculus must be regarded each as zero.

16. We now return to the consideration of the method of finding the derived functions or differential coefficients of the different forms of functions of x. Before doing so, however, it will be necessary to establish two or three general principles.

We commence with the differentiation of a product.

Let $y = uv$, where u and v are functions of x; then

$$\Delta y = (u + \Delta u)(v + \Delta v) - uv$$
$$= u\Delta v + (v + \Delta v)\Delta u;$$
$$\frac{\Delta y}{\Delta x} = u\frac{\Delta v}{\Delta x} + (v + \Delta v)\frac{\Delta u}{\Delta x};$$

proceeding to the limit, this becomes

$$\frac{d(uv)}{dx} = u\frac{dv}{dx} + v\frac{du}{dx}.$$

In like manner, if $y = uvw$, we get

$$\frac{dy}{dx} = vw\frac{du}{dx} + wu\frac{dv}{dx} + uv\frac{dw}{dx};$$

and, in general, if $y = y_1y_2y_3 \ldots y_n$ we have

$$\frac{1}{y}\frac{dy}{dx} = \frac{1}{y_1}\frac{dy_1}{dx} + \frac{1}{y_2}\frac{dy_2}{dx} + \ldots + \frac{1}{y_n}\frac{dy_n}{dx}.$$

Again, if $y = \frac{u}{v}$, we have $u = vy$, consequently

$$\frac{du}{dx} = v\frac{dy}{dx} + y\frac{dv}{dx};$$

$$\therefore \quad \frac{dy}{dx} = \frac{1}{v}\frac{du}{dx} - \frac{u}{v^2}\frac{dv}{dx} = \frac{v\frac{du}{dx} - u\frac{dv}{dx}}{v^2}.$$

17. Next, to differentiate a function of a function of x; let $y = f(x)$, and $u = \phi(y)$, to find $\frac{du}{dx}$. Suppose y_1, u_1 to be the values which y and u assume when x becomes x_1, then

$$\frac{u_1 - u}{x_1 - x} = \frac{u_1 - u}{y_1 - y} \cdot \frac{y_1 - y}{x_1 - x}, \text{ or } \frac{\Delta u}{\Delta x} = \frac{\Delta u}{\Delta y} \cdot \frac{\Delta y}{\Delta x}.$$

Hence, since, as proved already, the limit of the product of two variable quantities is the product of their limits, we have

$$\frac{du}{dx} = \frac{du}{dy} \cdot \frac{dy}{dx}.$$

Consequently, the derived function of u with respect to x is the product of its derived with respect to y and of the derived of y with respect to x. Again, if we suppose $u=x$, our equations become $y=f(x)$, and $x=\phi(y)$. In the former y is regarded as a function of x, and in the latter x as the corresponding function of y.

Such functions are said to be inverse to each other; and in this case we have—

$$1=\frac{dx}{dy}\cdot\frac{dy}{dx}, \text{ or } \frac{dx}{dy}=1\div\frac{dy}{dx}.$$

18. There exist in analysis a small number of simple or elementary functions, each of which requires a special investigation in order to find the corresponding derived function. When these have been established the differentiation of functions composed of these elementary functions can be readily obtained, by applying one or more of the principles just established.

19. We commence with the equation $y=x^n$, in which n is a constant.

(1) Let n be an integer, and y_1 the value which y assumes when x becomes x_1; then

$$\frac{y_1-y}{x_1-x}=\frac{x_1{}^n-x^n}{x_1-x}=x_1{}^{n-1}+xx_1{}^{n-2}+\ldots+x^{n-1}.$$

Now the limit of the right hand side when $x=x_1$ is nx^{n-1}; accordingly we have in this case

$$\frac{dx^n}{dx}=nx^{n-1}.$$

(2) Let $y=x^{\frac{m}{n}}$, where m and n are integers. Here $y^n=x^m$, and accordingly $ny^{n-1}\frac{dy}{dx}=mx^{m-1}$; hence we get $\frac{dy}{dx}=\frac{m}{n}x^{\frac{m}{n}-1}$.

(3) Let $y=x^{-m}=\frac{1}{x^m}$; then, from § 16, we get

$$\frac{dy}{dx}=-mx^{-m-1}.$$

Consequently we get the following rule, applicable in all cases, for the differentiation of a power of x:—

Diminish the index by unity, and multiply the power of x thus obtained by the original index.

20. We shall next consider the elementary circular and trigonometrical functions.

Let $y=\sin x$. Then $y_1=\sin(x+h)$;

$$\frac{y_1-y}{h}=\frac{\sin(x+h)-\sin x}{h}=\frac{2}{h}\sin\frac{h}{2}\cos\left(x+\frac{h}{2}\right).$$

But $\frac{2}{h}\sin\frac{h}{2}$ becomes unity in the limit, and consequently

$$\frac{dy}{dx}=\cos x.$$

In like manner it is easily seen that

$$\frac{d\cos x}{dx}=-\sin x.$$

Again, $$\frac{d\tan x}{dx}=\frac{d}{dx}\left|\frac{\sin x}{\cos x}\right|=\frac{\cos x\frac{d\sin x}{dx}-\sin x\frac{d\cos x}{dx}}{\cos^2 x}$$
$$=\frac{\cos^2x+\sin^2x}{\cos^2x}=\frac{1}{\cos^2x}=\sec^2x.$$

Similarly $$\frac{d\cot x}{dx}=-\frac{1}{\sin^2x},\quad\frac{d\sec x}{dx}=\sec x\tan x.$$

Corresponding to these trigonometrical functions we have the circular functions, $\sin^{-1}x$, $\cos^{-1}x$, $\tan^{-1}x$, etc.

If $y=\sin^{-1}x$, we have $x=\sin y$, and hence

$$\frac{dx}{dy}=\cos y, \text{ or } \frac{dy}{dx}=\frac{1}{\cos y}=\frac{1}{\sqrt{1-x^2}};$$

$$\therefore\qquad\frac{d\sin^{-1}x}{dx}=\frac{1}{\sqrt{1-x^2}}.$$

In like manner

$$\frac{d\cos^{-1}x}{dx}=\frac{-1}{\sqrt{1-x^2}},\quad\frac{d\tan^{-1}x}{dx}=\frac{1}{1+x^2}.$$

21. Next, let $y=\log_a x$. Here $y_1=\log_a(x+h)$;

$$\therefore\quad\frac{y_1-y}{h}=\frac{1}{h}\log_a\left(\frac{x+h}{x}\right)=\frac{1}{h}\log_a\left(1+\frac{h}{x}\right).$$

Let $\frac{h}{x}=u$; then

$$\frac{1}{h}\log_a\left(1+\frac{h}{x}\right)=\frac{1}{xu}\log_a(1+u)=\frac{1}{x}\log_a(1+u)^{\frac{1}{u}}.$$

The limiting value of $(1+u)^{\frac{1}{u}}$ when $u=0$, *i. e.*, of $\left(1+\frac{1}{z}\right)^z$ when z increases indefinitely, is represented by the letter e (see ALGEBRA, vol. i. p. 492), and is the base of the natural or Napierian system of logarithms. Hence we have

$$\frac{d\log_a x}{dx}=\frac{1}{x}\log_a e.$$

If e be taken as the base of our system of logarithms, we have

$$\frac{d\log x}{dx}=\frac{1}{x}.$$

In our subsequent investigations we shall suppose all logarithms, unless otherwise specified, referred to this base, and omit the suffix.

22. The method of differentiation of an exponential function follows immediately from the preceding.

For let $y=a^x$, then $\log y=x\log a$,

$$\therefore\quad\frac{1}{y}\frac{dy}{dx}=\log a, \text{ or } \frac{dy}{dx}=a^x\log a.$$

We add a few examples for the purpose of showing the application of the preceding results to the differentiation of more complex functions.

(1) $y=x^x$.

Here $\log y=x\log x$; $\quad\therefore\quad\frac{1}{y}\frac{dy}{dx}=\log x+1$.

Hence $\frac{dy}{dx}=(1+\log x)x^x$.

(2) $y=\log\frac{x}{\sqrt{a^2+x^2}}$.

Here $y=\log x-\frac{1}{2}\log(a^2+x^2)$;

$$\therefore\quad\frac{dy}{dx}=\frac{1}{x}-\frac{x}{a^2+x^2}=\frac{a^2}{x(a^2+x^2)}.$$

(3) $y=\log\frac{\sqrt{1+x}+\sqrt{1-x}}{\sqrt{1+x}-\sqrt{1-x}}$.

Here $y=\frac{1}{2}\log\left(\frac{\sqrt{1+x}+\sqrt{1-x}}{\sqrt{1+x}-\sqrt{1-x}}\right)^2=\frac{1}{2}\log\frac{1+\sqrt{1-x^2}}{1-\sqrt{1-x^2}}$

$$=\tfrac{1}{2}\log(1+\sqrt{1-x^2})-\tfrac{1}{2}\log(1-\sqrt{1-x^2});$$

$$\therefore\quad\frac{dy}{dx}=\frac{-x}{2\sqrt{1-x^2}(1+\sqrt{1-x^2})}-\frac{x}{2\sqrt{1-x^2}(1-\sqrt{1-x^2})}$$
$$=\frac{-1}{x\sqrt{1-x^2}}.$$

(4) Prove that $\sin^2x\frac{d}{dx}(\sin^n x\sin nx)=n\sin^{n+1}x\sin(n+1)x$.

Here $\frac{d}{dx}(\sin^n x\sin nx)=n\sin^{n-1}x$
$(\cos x\sin nx+\sin x\cos nx)$
$=n\sin^{n-1}x\sin(n+1)x$; $\quad\therefore$ etc.

(5) $y=\tan^{-1}\frac{\sqrt{1+x^2}+\sqrt{1-x^2}}{\sqrt{1+x^2}-\sqrt{1-x^2}}$.

Here $\frac{\sqrt{1+x^2}+\sqrt{1-x^2}}{\sqrt{1+x^2}-\sqrt{1-x^2}}=\tan y$; from this we get

$x^2=\sin 2y$;

$$\therefore\quad\frac{dy}{dx}=\frac{x}{\cos 2y}=\frac{x}{\sqrt{1-x^4}}.$$

(6) If $y=\log\sin x$, prove that $\frac{dy}{dx}=\cot x$.

(7) If $y=e^{x^x}$, prove that $\frac{dy}{dx}=e^{x^x}x^x(1+\log x)$.

(8) If $y=\frac{1}{x}$, prove that

$$\frac{dy}{\sqrt{1+y^4}}+\frac{dx}{\sqrt{1+x^4}}=0.$$

(9) If $y=\log(\sqrt{x+a}+\sqrt{x+b})$, prove that

$$\frac{dy}{dx}=\frac{1}{2\sqrt{(x+a)(x+b)}}.$$

23. We shall conclude this section with the consideration of the differential of the area ABPM (Fig. 3) of a plane

curve, comprised between the curve, the axis of x, and two ordinates, of which one BA is fixed and the other PM is variable, x, y representing the co-ordinates of P. This area, when the equation of the curve is given, is an *implicit function* of x. If it be represented by u, we proceed to find its differential coefficient, or $\frac{du}{dx}$. Suppose x to receive an indefinitely small increment represented by MM′, the corresponding increment of the area is represented by PMM′P′, *i.e.*, by the sum of the rectangle PMM′R and the elementary area PP′R. Now the latter area becomes evanescent in the limit in comparison with PMM′R.

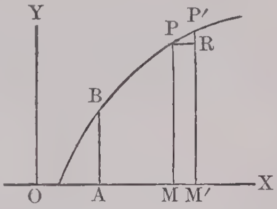

Fig. 3.

Consequently in proceeding to the limit we have $\frac{du}{dx} =$ PM $= y$, or $\frac{du}{dx} = \phi(x)$, where $y = \phi(x)$ is the equation of the curve.

From this we can make an important inference, viz., that in all cases there exists a function whose differential coefficient is any given function of x, suppose $\phi(x)$. To find such a function it is sufficient to consider the curve whose equation in rectangular co-ordinates is $y = \phi(x)$; then the area comprised between any fixed ordinate and the ordinate whose abscissa is x is a determinate function,—which, by the preceding, has $\phi(x)$ for its derived function.

Successive Differentiation.

24. We have seen that from any function of a variable we can obtain by differentiation a new function, called its differential coefficient, or, after Lagrange, its derived function.

If the primitive function be represented by $f(x)$, then, as already stated, its *first* derived function is denoted by $f'(x)$. If this new function, $f'(x)$, be treated in the same manner, its derived function is called the *second* derived of the original function $f(x)$, and is denoted by $f''(x)$. In like manner, the derived function of $f''(x)$ is the *third* derived of $f(x)$, and represented by $f'''(x)$, etc. In accordance with this notation, the successive derived functions of $f(x)$ are represented by

$$f'(x)\,,\ f''(x)\,,\ f'''(x)\,,\ \ldots\ f^{(n)}(x)\,,$$

each of which is the derived function of the preceding.

25. In like manner, if $y = f(x)$, then $\frac{dy}{dx} = f'(x)$.

Hence $$\frac{d\left(\frac{dy}{dx}\right)}{dx} = \frac{df'(x)}{dx} = f''(x).$$

The function $\frac{d\left(\frac{dy}{dx}\right)}{dx}$ is written $\frac{d^2y}{dx^2}$, and is called the second differential coefficient of y with regard to x.

Likewise $\frac{d\frac{d^2y}{dx^2}}{dx}$ is written $\frac{d^3y}{dx^3}$, and so on;

and the series of functions

$$\frac{dy}{dx}\,,\ \frac{d^2y}{dx^2}\,,\ \frac{d^3y}{dx^3}\ \ldots\ \frac{d^ny}{dx^n}$$

are called the first, second, third, . . . nth *differential coefficients* of the function represented by y.

It is sometimes convenient to adopt a notation analogous to that of fluxions, and to represent the series of differential coefficients of y by

$$y'\,,\ y''\,,\ y'''\,,\ \ldots\ y^{(n)},$$

in order to abbreviate the labor of writing down the system of successive differential coefficients.

26. It is plain that the determination of the series of successive derived functions of any function of x does not require any new principles, as it is accomplished by successive applications of the methods already considered.

For example, if $y = x^n$, we have

$$\frac{dy}{dx} = nx^{n-1},$$

hence $$\frac{d^2y}{dx^2} = n(n-1)x^{n-2},\quad \frac{d^3y}{dx^3} = n(n-1)(n-2)x^{n-3}, \text{ etc.}$$

Again, if $y = e^{ax}$, we have

$$\frac{dy}{dx} = ae^{ax},\quad \frac{d^2y}{dx^2} = a^2e^{ax}, \text{ etc.}$$

and in general $$\frac{d^ny}{dx^n} = a^ne^{ax}.$$

27. We next proceed to a fundamental theorem due to Leibnitz, and first published in *Mis. Berol.*, 1710, viz., to find the nth derived function of the product of two functions.

Let $y = uv$; then, if we write y', u', v', y'', u'', etc., for

$$\frac{dy}{dx},\ \frac{du}{dx},\ \frac{dv}{dx},\ \frac{d^2y}{dx^2}, \text{ etc.},$$

we have $y' = uv' + vu'$.

The next differentiation gives

$$y'' = uv'' + u'v' + v'u' + vu'' = uv'' + 2u'v' + vu''.$$

The third differentiation gives

$$\begin{aligned} y''' &= uv''' + u'v'' + 2u'v'' + 2u''v' + v'u'' + vu''' \\ &= uv''' + 3u'v'' + 3u''v' + vu''', \end{aligned}$$

in which the coefficients are the same as those in the expansion of $(a+b)^3$.

Suppose that the same law holds for the nth differential coefficient, and that

$$y^{(n)} = uv^{(n)} + nu'v^{(n-1)} + \frac{n(n-1)}{1\,.\,2}u''v^{(n-2)} + \text{etc.}, \qquad + nu^{(n-1)}v' + u^{(n)}v\,;$$

then, differentiating again, we get

$$\begin{aligned} y^{(n+1)} &= uv^{(n+1)} + u'v^{(n)} + n(u'v^{(n)} + u''v^{(n-1)} \\ &\quad + \frac{n(n-1)}{2}(u''v^{(n-1)} + u'''v^{(n-2)} + \text{etc.}\ \ldots + u^{(n+1)}v \\ &= uv^{(n+1)} + (n+1)u'v^{(n)} + \frac{(n+1)n}{1\,.\,2}u''v^{(n-1)} + \text{etc.}\ \ldots, \end{aligned}$$

in which the coefficients follow the law of the Binomial Expansion.

Accordingly, if this law hold for any integer value of n, it holds for the next higher integer; but it holds when $n = 3$, therefore it holds for $n = 4$, etc.

In the ordinary notation the preceding result is written

$$\frac{d^n(uv)}{dx^n} = u\frac{d^nv}{dx^n} + n\frac{du}{dx}\frac{d^{n-1}v}{dx^{n-1}} + \frac{n(n-1)}{1\,.\,2}\frac{d^2u}{dx^2}\frac{d^{n-2}v}{dx^{n-2}} + \text{etc.} + v\frac{d^nu}{dx^n}.$$

(1) If $y = e^{ax}\sin bx$, to find $\frac{d^ny}{dx^n}$.

Here $$\frac{dy}{dx} = e^{ax}(a\sin bx + b\cos bx).$$

Now let $b = a\tan\phi$, and we have

$$\begin{aligned} \frac{dy}{dx} &= (a^2+b^2)^{\frac{1}{2}}e^{ax}(\sin bx\cos\phi + \cos bx\sin\phi) \\ &= (a^2+b^2)^{\frac{1}{2}}e^{ax}\sin(bx+\phi). \end{aligned}$$

Similarly we get $\frac{d^2y}{dx^2} = (a^2+b^2)e^{ax}\sin(bx+2\phi)$;

and, in general, $\frac{d^ny}{dx^n} = (a^2+b^2)^{\frac{n}{2}}e^{ax}\sin(bx+n\phi)$.

(2) If $y = \cot^{-1}x$, to find $\frac{d^ny}{dx^n}$.

Here $$x = \cot y, \quad \therefore \quad \frac{dy}{dx} = -\sin^2y,$$

hence $$\begin{aligned} \frac{d^2y}{dx^2} &= -\frac{d}{dx}(\sin^2y) = -\frac{dy}{dx}\cdot\frac{d}{dy}(\sin^2y) \\ &= \sin^2y\frac{d}{dy}(\sin^2y) = \sin^2y\sin 2y. \end{aligned}$$

Again $$\begin{aligned} \frac{d^3y}{dx^3} &= \frac{d}{dx}(\sin^2y\sin 2y) = \frac{dy}{dx}\frac{d}{dy}(\sin^2y\sin 2y) \\ &= -\sin^2y\frac{d}{dy}(\sin^2y\sin 2y) \\ &= -1\,.\,2\sin^3y\sin 3y. \qquad \text{(Ex. 4, § 22.)} \end{aligned}$$

In like manner,

$$\frac{d^4y}{dx^4} = 1\,.\,2\,.\,3\sin^4y\sin 4y.$$

And, in general, $\frac{d^ny}{dx^n} = (-1)^n\,.\,\underline{|n-1}\sin^ny\sin ny$.

(3) If $y = x^{n-1}\log x$, prove that $\frac{d^ny}{dx^n} = \frac{\underline{|n-1}}{x}$.

(4) If $y = \cos(a\sin^{-1}x)$, prove that

$$(1-x^2)\frac{d^2y}{dx^2} - x\frac{dy}{dx} + a^2y = 0.$$

(5) If $y = a \cos nx + b \sin nx$, prove that

$$\frac{d^2y}{dx^2} + n^2y = 0.$$

(6) If $u = xy$, prove that

$$\frac{d^nu}{dx^n} = x\frac{d^ny}{dx^n} + n\frac{d^{n-1}y}{dx^{n-1}}.$$

Partial Differentiation.

28. We have hitherto treated of functions of a single independent variable solely. The principles established so far apply equally to the case of functions of two or more independent variables.

For example, in the equation

$$u = ax^2 + 2bxy + cy^2,$$

the variables x and y may be capable of change independently of each other; and if we suppose x to vary, y remaining constant, the corresponding differential coefficient of u is represented by $\frac{du}{dx}$, and we have

$$\frac{du}{dx} = 2ax + 2by.$$

In the same case if we suppose y to vary, x being unchanged, the corresponding differential coefficient is represented by $\frac{du}{dy}$, and we have

$$\frac{du}{dy} = 2bx + 2cy.$$

In general, if u be a function of two variables, x and y, represented by the equation

$$u = \phi(x, y),$$

we have two differential coefficients

$$\frac{du}{dx} \text{ or } \frac{d\phi(x\,,\,y)}{dx}, \text{ and } \frac{du}{dy} \text{ or } \frac{d\phi(x\,,\,y)}{dy}$$

These are called the *partial differential coefficients* of the function, with regard to x and y respectively. They are usually written $\frac{d\phi}{dx}$ and $\frac{d\phi}{dy}$, and are plainly determined in the same manner as in the case of a single variable.

29. These new functions $\frac{du}{dx}$ and $\frac{du}{dy}$ admit of being treated in like manner. Thus the partial differential coefficient of $\frac{du}{dx}$, taken with respect to x, y being supposed unchanged, is represented by $\frac{d\frac{du}{dx}}{dx}$ or by $\frac{d^2u}{dx^2}$; likewise its differential coefficient with respect to y is represented by $\frac{d^2u}{dydx}$; and so on.

30. It can be seen without difficulty that

$$\frac{d^2u}{dxdy} = \frac{d^2u}{dydx}, \textit{ i. e., } \frac{d\frac{du}{dx}}{dy} = \frac{d\frac{du}{dy}}{dx}.$$

In fact $\frac{d^2u}{dydx}$ signifies the limit to which $\frac{\Delta\frac{\Delta u}{\Delta x}}{\Delta y}$ approaches as Δx and Δy diminish beyond limit.

Again $$\frac{\Delta u}{\Delta x} = \frac{\phi(x + \Delta x\,,\,y) - \phi(x\,,\,y)}{\Delta x}.$$

In like manner,

$$\frac{\Delta\frac{\Delta u}{\Delta x}}{\Delta y} = \frac{\frac{\phi(x + \Delta x\,,\,y + \Delta y) - \phi(x + \Delta x\,,\,y)}{\Delta x} - \frac{\phi(x\,,y + \Delta y) - \phi(x\,,\,y)}{\Delta x}}{\Delta y}$$

$$= \frac{\phi(x + \Delta x\,,\,y + \Delta y) - \phi(x + \Delta x\,,\,y) - \phi(x\,,\,y + \Delta y) + \phi(x\,,\,y)}{\Delta x\Delta y}.$$

It is easily seen that $\frac{\Delta\frac{\Delta u}{\Delta y}}{\Delta x}$ has the same value. Accordingly the limits of the two expressions must be equal, and hence we infer

$$\frac{d^2u}{dydx} = \frac{d^2u}{dxdy}.$$

31. In general, if u be a function of several independent variables $x_1, x_2, \ldots x_n$, we obtain n partial differential coefficients of the first order, denoted by

$$\frac{du}{dx_1}, \frac{du}{dx_2}, \frac{du}{dx_3}, \ldots \frac{du}{dx_n}.$$

In like manner, the partial differential coefficients of the second order are represented by

$$\frac{d^2u}{dx_1^2}, \frac{d^2u}{dx_1dx_2}, \frac{d^2u}{dx_2^2}, \text{ etc., and so on.}$$

We have, as in the former case, between each pair of variables

$$\frac{d^2u}{dx_1dx_2} = \frac{d^2u}{dx_2dx_1}, \text{ etc.}$$

32. In the equation $u = \phi\,(x,y)$, if we consider x and y to increase simultaneously, then, if Δu represents the total increment of u, we have

$$\Delta u = \phi\,(x + \Delta x\,,\,y + \Delta y) - \phi\,(x\,,\,y)$$

$$= \phi(x + \Delta x\,,\,y + \Delta y) - \phi(x\,,\,y + \Delta y) + \phi(x\,,\,y + \Delta y) - \phi(x\,,\,y)$$

$$= \frac{\phi(x + \Delta x, y + \Delta y) - \phi(x, y + \Delta y)}{\Delta x}\Delta x + \frac{\phi(x\,, y + \Delta y) - \phi(x\,,\,y)}{\Delta y}\Delta y.$$

If now we suppose Δx and Δy to diminish indefinitely, and represent the corresponding differentials by du, dx, dy, we have in the limit

$$du = \frac{du}{dx}dx + \frac{du}{dy}dy.$$

This is called the *total differential* of u, and it is readily seen that it is equal to the sum of the partial differentials arising from the separate increments in x and y. The same principle plainly holds in a function of any number of variables.

33. If $u = \phi\,(v, w)$, where v and w are both functions of x, then by the preceding it is readily seen that

$$\frac{du}{dx} = \frac{du}{dv}\frac{dv}{dx} + \frac{du}{dw}\frac{dw}{dx};$$

and similarly for any number of functions.

34. The principles of total and partial differentiation admit of simple illustration in plane and in spherical trigonometry. For, in either a plane or a spherical triangle, we may regard *any three*[1] of the parts a, b, c, A, B, C as being *independent* variables, and each of the others as a function of the three so chosen.

For instance, in a plane triangle, if the sides a and b and the contained angle C be taken as the independent variables, we have

$$c^2 = a^2 + b^2 - 2ab \cos \mathrm{C};$$

hence $$\frac{dc}{da} = \frac{a - b\cos \mathrm{C}}{c} = \cos \mathrm{B};$$

likewise $$\frac{dc}{db} = \cos \mathrm{A}, \quad \frac{dc}{d\mathrm{C}} = a \sin \mathrm{B},$$

$$\therefore\ dc = \cos \mathrm{B}\, da + \cos \mathrm{A}\, db + a \sin \mathrm{B}\, d\mathrm{C}.$$

Again, to find $\frac{d\mathrm{A}}{d\mathrm{C}}$, we have $b \sin \mathrm{A} = a \sin \mathrm{B} = a \sin(\mathrm{A}+\mathrm{C})$; hence, regarding a and b as constant, we have

$$b \cos \mathrm{A}\frac{d\mathrm{A}}{d\mathrm{C}} = a\cos(\mathrm{A}+\mathrm{C})\left(1 + \frac{d\mathrm{A}}{d\mathrm{C}}\right) = -a\cos \mathrm{B} - a\cos \mathrm{B}\frac{d\mathrm{A}}{d\mathrm{C}};$$

$$\therefore \frac{d\mathrm{A}}{d\mathrm{C}} = -\frac{a\cos \mathrm{B}}{c}.$$

In like manner we have, in the same case,

$$\frac{d\mathrm{A}}{da} = \frac{\sin \mathrm{B}}{c}, \quad \frac{d\mathrm{A}}{db} = -\frac{\sin \mathrm{A}}{c}.$$

$$\therefore\ d\mathrm{A} = \frac{\sin \mathrm{B}}{c}da - \frac{\sin \mathrm{A}}{c}db - \frac{a\cos \mathrm{B}}{c}d\mathrm{C}.$$

Again, in a spherical triangle,

$$\cos c = \cos a \cos b + \sin a \sin b \cos \mathrm{C}.$$

From this we obtain

$$\frac{dc}{da} = \cos \mathrm{B}, \quad \frac{dc}{db} = \cos \mathrm{A}, \quad \frac{dc}{d\mathrm{C}} = \sin a \sin \mathrm{B},$$

$$\therefore\ dc = \cos \mathrm{B}\, da + \cos \mathrm{A}\, db + \sin a \sin \mathrm{B}\, d\mathrm{C}.$$

This, and the preceding also admit of a simple geometrical demonstration, by drawing the triangle and comparing the small increments in each case.

35. Again, since from any equation in spherical trigonometry another can be deduced by aid of the *polar triangle*, we get from the preceding

$$d\mathrm{C} = -\cos b\, d\mathrm{A} - \cos a\, d\mathrm{B} + \sin \mathrm{A} \sin b\, dc.$$

---

[1] The case of the three angles of a plane triangle is excepted, as they are equivalent to but *two independent data*.

Corresponding formulæ are obtained by an interchange of letters.

Again, the infinitesimals da, db, dA, dB are connected by the equation

$$\frac{da}{\tan a}+\frac{dB}{\tan B}=\frac{dA}{\tan A}+\frac{db}{\tan b}.$$

This follows immediately from the equation

$$\sin a \sin B = \sin A \sin b.$$

36. These and the analogous formulæ, when we adopt small differences instead of differentials, are of importance in astronomy in determining the errors in a computed distance arising from small errors in observation. They also enable us to determine the circumstances under which the most favorable observations are made, viz., those for which small errors in observation produce the least error in the required result.

The relations between the variations in the sides and angles of plane and spherical triangles were first treated of by Cotes, in his *Estimatio Errorum in Mixta Mathesi* (1722).

(1.) The values of $\frac{dy}{dx}$ and $\frac{dz}{dx}$, when x, y, z are connected by two equations of the form $f(x, y, z)=0$, $\phi(x, y, z)=0$, are found to be

$$\frac{dy}{dx}=\frac{\frac{df}{dx}\frac{d\phi}{dz}-\frac{df}{dz}\frac{d\phi}{dx}}{\frac{df}{dz}\frac{d\phi}{dy}-\frac{df}{dy}\frac{d\phi}{dz}},\quad \frac{dz}{dx}=\frac{\frac{df}{dy}\frac{d\phi}{dx}-\frac{df}{dx}\frac{d\phi}{dy}}{\frac{df}{dz}\frac{d\phi}{dy}-\frac{df}{dy}\frac{d\phi}{dz}}.$$

(2) If $f(u)=\phi(v)$, where u and v are each functions of x and y, it is easily shown that

$$\frac{du}{dx}\frac{dv}{dy}-\frac{du}{dy}\frac{dv}{dx}=0.$$

(3) In a spherical triangle, if $\frac{\sin C}{\sin c}$ be constant, and equal to κ, the relations

$$\frac{da}{\cos A}+\frac{db}{\cos B}+\frac{dc}{\cos C}=0,$$

and

$\cos A\, da+\cos B\, db+\cos C\, dc=\kappa^2 d\,(\sin a \sin b \sin c)$ can be readily established.

(4) More generally, it may be shown that, if κ also be supposed to vary

$$\frac{da}{\cos A}+\frac{db}{\cos B}+\frac{dc}{\cos C}=\tan A \tan B \tan C d\left(\frac{1}{\kappa}\right),$$

and

$$\cos A\, da+\cos B\, db+\cos C\, dc=\kappa d(\kappa \sin a \sin b \sin c).$$

(5) If u be a function of ξ,η,ζ, and $\xi=y+\frac{1}{z}$, $\eta=z+\frac{1}{x}$, $\zeta=x+\frac{1}{y}$, show that

$$x\frac{du}{dx}+y\frac{du}{dy}+z\frac{du}{dz}+\xi\frac{du}{d\xi}+\eta\frac{du}{d\eta}+\zeta\frac{du}{d\zeta}$$
$$=2\left(x\frac{du}{d\zeta}+y\frac{du}{d\xi}+z\frac{du}{d\eta}\right).$$

Taylor's Theorem and Development of Functions.

37. We have already noticed that the development of functions by infinite series was a branch of analysis that rose into prominence during the latter portion of the 17th century.

The first series thus published were—that of Nicholas Mercator in his *Logarithmotechnia* (1668) for the expansion of log $(1+x)$, or what was then styled the area of an hyperbola (this he arrived at by the aid of Wallis's method of quadratures); and that of James Gregory, in a letter to J. Collins, 1671, for the expansion of an arc in terms of its tangent. About the same time the first efforts of Newton's genius were directed to this subject; and, as we have already seen, he thus arrived at his binomial theorem, and other general expansions, such as those of $\sin x$, $\cos x$, e^x, etc.

It was not, however, until many years after these discoveries that it was found that all such expansions may be regarded as particular cases of one general theorem. This theorem was discovered by Dr. Brook Taylor, and published by him in 1715 in his *Methodus Incrementorum*.

38. Before proceeding to a consideration of this important series it should be observed that, in 1694, John Bernoulli published, in the *Acta Eruditorum*, his well-known expansion under the title *Additamentum effectionis omnium quadraturarum et rectificationum curvarum per seriem quandam generalissimam.* This series may be written as follows, slightly altering Bernoulli's notation:—

$$\int y dx = xy-\frac{x^2}{1.2}\frac{dy}{dx}+\frac{x^3}{1.2.3}\frac{d^2y}{dx^2}-\text{etc.}$$

Bernoulli obtained this result immediately by differentiation, by which process it can be easily verified.

This is the first general theorem on series that was discovered; and it was easily shown by its author that the ordinary series, such as the expansions of log $(1+x)$, of $\sin x$, and others, can be deduced from it.

This theorem of Bernoulli, however, is but a particular case of Taylor's, as will be shown subsequently.

39. Taylor arrived at his theorem as a particular case of another in *finite differences*,—a branch of the calculus treated of for the first time in his *Meth. Increm.* Introducing the modern notation, Taylor's proof, with some modifications, is as follows.

Let $f(x)$ be any function of x, and suppose x changed successively into

$$x+\Delta x,\quad x+2\Delta x,\quad x+3\Delta x,\quad \ldots\quad x+n\Delta x;$$

and let the functions

$$f(x),\ f(x+\Delta x),\ f(x+2\Delta x),\quad \ldots\quad f(x+n\Delta x)$$

be represented by

$$y,\ y_1,\ y_2,\quad \ldots\quad y_n.$$

Then we have

$$y_1-y=\Delta y,\ y_2-y_1=\Delta y_1,\quad \ldots\quad y_n-y_{n-1}=\Delta y_{n-1},$$
$$\Delta y_1-\Delta y=\Delta^2 y,\quad \Delta y^2-\Delta y_1=\Delta^2 y_1,\ \Delta y_n-\Delta y_{n-1}=\Delta^2 y_{n-1},$$
$$\Delta^2 y_1-\Delta^2 y=\Delta^3 y,\ \text{etc.}$$

The final result consists in expressing y_n in terms of

$$y,\ \Delta y,\ \Delta^2 y,\quad \ldots\quad \Delta^n y.$$

We have

$$y_n=y_{n-1}+\Delta y_{n-1}=y_{n-2}+2\Delta y_{n-2}+\Delta^2 y_{n-2}.$$

In like manner, substituting $y_{n-3}+\Delta y_{n-3}$ for y_{n-2}, we get

$$y_n=y_{n-3}+3\Delta y_{n-3}+3\Delta^2 y_{n-3}+\Delta^3 y_{n-3},$$

the coefficients being the same as those in the expansion of $(a+b)^3$. Now, if we assume that the same law holds for any value n, it is readily seen by the method of mathematical induction, of which we have given an example in § 27, that it holds for the value immediately superior; and we thus get

$$y_n=y+n\Delta y+\frac{n.(n-1)}{1.2}\Delta^2 y+\frac{n.(n-1)(n-2)}{1.2.3}\Delta^3 y+\ldots+\Delta^n y.$$

40. This result can be readily established also by the principles of the symbolic calculus, a branch of the subject to which a short space will be devoted subsequently. We shall anticipate the consideration of that method by giving an application of it to the determination of the preceding result.

Regarding Δ as a *symbol* of operation, the equation $y_n=y_{n-1}+\Delta y_{n-1}$ may be written $y_n=(1+\Delta)\,y_{n-1}$.

In like manner, $y_{n-1}=(1+\Delta)y_{n-2}$

$$\therefore\quad y_n=(1+\Delta)(1+\Delta)y_{n-2}=(1+\Delta)^2 y_{n-2},$$

also $y_n=(1+\Delta)^3 y_{n-3}$; and in general

$$y_n=(1+\Delta)^n y$$
$$=\left(1+n\Delta+\frac{n.(n-1)}{1.2}\Delta^2+\quad\ldots\quad+\Delta^n\right)y$$
$$=y+n\Delta y+\frac{n.(n-1)}{1.2}\Delta^2 y+\quad\ldots\quad\Delta^n y.$$

41. If we suppose

$$n\Delta x=h.\ \text{or}\ n=\frac{h}{\Delta x},$$

the equation becomes

$$f(x+h)=y+h\frac{\Delta y}{\Delta x}+\frac{h.(h-\Delta x)}{1.2}\frac{\Delta^2 y}{\Delta x^2}+\text{etc.}$$

If now, h being regarded as constant, we suppose n to increase, and consequently Δx to diminish, indefinitely, we obtain, on proceeding to the limit,

$$f(x+h)=y+h\frac{dy}{dx}+\frac{h^2}{1.2}\frac{d^2y}{dx^2}+\text{etc.}$$
$$=f(x)+hf'(x)+\frac{h^2}{1.2}f''(x)+\frac{h^3}{1.2.3}f'''(x)+\text{etc.}$$

This is called Taylor's series.

42. In order to complete the investigation, it will be necessary to examine into the convergency or divergency of the series, and to obtain an expression for the remainder in it after any number of terms; this we shall immediately proceed to consider.

43. It may be observed that Taylor does not seem to have been aware of the great importance of his theorem, nor

did he give any examples of its application. This probably accounts for the fact that so long a time elapsed before its real value was discovered; and, although Stirling introduced a particular case of it in his *Methodus Differentialis* (1717), it was not noticed in any of the English treatises on the calculus—such as Simpson's *Fluxions* (1737), Emerson's *Fluxions* (1743), Landen's *Residual Analysis* (1764),—nor is it mentioned in the first edition of Montucla's *Hist. des Math.*, 1758. The theorem is to be found in Euler's *Cal. Dif.* (1755); but, although Euler makes extensive use of it, he made no reference to Taylor's name in connection with the series, and would appear to have given the theorem as his own, or rather perhaps to have connected it with Bernoulli's series.

44. We may observe that Taylor also introduced into his *Methodus Incrementorum*, in the fluxional notation, a series which is the same as that of Bernoulli, already noticed. This led to a long and bitter controversy between them, in which Bernoulli's son Nicholas and others also took part. In this Taylor was accused of plagiarism both with respect to this theorem and to other theorems relative to the general theory of the centre of oscillation of bodies. It is remarkable that in this dispute no reference was made to Taylor's own theorem, nor do the disputants seem to have been aware of its vast superiority to that around which the angry controversy was raised.

45. Taylor's theorem seems never to have risen into due prominence until its great value was pointed out by the illustrious Lagrange, in the Berlin memoirs for 1772. Lagrange demonstrated the theorem by the principles of ordinary algebra. He made it the foundation of the method of series, and also of the differential calculus. He thus proposed to make the calculus a branch of ordinary algebra, and independent of all considerations of infinitely small quantities, and so to give it all the formal rigor of demonstration of the method of the ancients.

46. Lagrange also was the first to place Taylor's theorem on a satisfactory basis by finding an expression for the remainder of the series after any number of terms.

The following demonstration of this theorem of Lagrange depends on a single lemma, which may be thus stated. *If a continuous function* f(x) *vanish when* x = a, *and also when* x = b, *then its derived function* f′(x), *if also continuous, must also vanish for some value of* x *between* a *and* b.

This is easily proved; for if $f'(x)$ does not vanish for some value of x between a and b, it must have always the same sign between these limits, and consequently $f(x)$ must constantly increase or constantly diminish as x passes by small increments from the value a to the value b; but this is impossible, since $f(x)$ vanishes for both limits. Now let R_n represent the remainder after n terms in Taylor's expansion, then writing X for $x+y$ in that series we have

$$f(X)=f(x)+\frac{(X-x)}{1}f'(x)+\frac{(X-x)^2}{1.2}f''(x)+\ldots$$
$$+\frac{(X-x)^{n-1}}{\underline{|n-1}}f^{(n-1)}(x)+R_n\,,\quad\ldots\;(\alpha),$$

in which $f(x), f'(x)\;\ldots\ldots\;f^{(n-1)}(x)$ are supposed finite and continuous for all values of the variable between X and x.

From the form of the terms included in R_n it evidently may be written in the shape

$$R_n=\frac{(X-x)^n}{\underline{|n}}P,$$

where P is some function of X and x. Consequently we have

$$f(X)-\left\{f(x)+\frac{(X-x)}{1}f'(x)+\ldots+\frac{(X-x)^{n-1}}{\underline{|n-1}}f^{(n-1)}(x)\right.$$
$$\left.+\frac{(X-x)^n}{\underline{|n}}P\right\}=0\quad\ldots\ldots\ldots\;(\beta).$$

Now, let z be substituted for x in every term in the preceding, *with the exception of* P, and let F(z) represent the resulting expression, we shall have

$$F(z)=f(X)-\left\{f(z)+\frac{(X-z)}{1}f'(z)+\ldots+\frac{(X-z)^n}{\underline{|n}}P\right\}\ldots(\gamma),$$

in which P has the same value as before.

Again, the right-hand side in this equation vanishes when $z=X$,

$$\therefore\quad F(X)=0.$$

Also, from (β), the right-hand side vanishes when $z=x$;

$$\therefore\quad F(x)=0.$$

Accordingly, since the function F(z) vanishes when $z=X$, and also when $z=x$, it follows from the preceding lemma that its derived function F′(z) also vanishes for some value of z between the limits X and x.

Proceeding to obtain F′(z) by differentiation, it can be easily seen from equation (γ) that we have

$$F'(z)=-\frac{(X-z)^{n-1}}{\underline{|n-1}}f^{(n)}(z)+\frac{(X-z)^{n-1}}{\underline{|n-1}}P.$$

Consequently, for some value of z between x and X we must have $f^{(n)}(z)=P$.

Again, if θ be a positive quantity less than unity, the expression $x+\theta(X-x)$, by assigning a suitable value to θ, can be made equal to any number intermediate between x and X.

Hence

$$P=f^{(n)}\{x+\theta(X-x)\}\,,$$

where θ is some quantity >0 and <1.

Consequently, the remainder after n terms of Taylor's series can be represented by

$$=\frac{(X-x)^n}{\underline{|n}}f^{(n)}\{x+\theta(X-x)\}\,.$$

This is Lagrange's form for the remainder. Substituting this value for R_n in (α), it becomes

$$f(X)=f(x)+\frac{(X-x)}{1}f'(x)+\frac{(X-x)^2}{1.2}f''(x)+\ldots$$
$$+\frac{(X-x)^{n-1}}{\underline{|n-1}}f^{(n-1)}(x)+\frac{(X-x)^n}{\underline{|n}}f^{(n)}\{x+\theta(X-x)\}\,.$$

Again, if h be substituted for $X-x$, the series becomes

$$f(x+h)=f(x)+hf'(x)+\text{etc.}+\frac{h^{n-1}}{\underline{|n-1}}f^{(n-1)}(x)+\frac{h^n}{\underline{|n}}f^{(n)}(x+\theta h).$$

In this expression n may be any positive integer.

47. The last equation may be regarded as the most general form of Taylor's theorem. We infer from it that the essential conditions for the application of Taylor's theorem to the expansion of any function in a series are—that none of its derived functions should become infinite, and that $\frac{h^n}{\underline{|n}}f^{(n)}(x+\theta h)$ should become infinitely small when n becomes sufficiently large.

48. The remainder in Taylor's series admits, as was shown by Cauchy, of being written in the form

$$\frac{h^n(1-\theta)^{n-1}}{\underline{|n-1}}f^{(n)}(x+\theta h)\,.$$

Another form was given by Dr. Schlömilch, viz.

$$R_n=\frac{h^n(1-\theta)^{n+p-1}}{\underline{|n-1}\;(p+1)}f^{(n)}(x+\theta h)\,.$$

In some cases one or other of these latter values is preferable to Lagrange's form.

49. Another remarkable mode of determining the remainder in Taylor's theorem was also given by Cauchy. It is based on the following lemma, that if F(x) and $f(x)$ be two functions which remain continuous, as also their derived functions, between the values x_1 and x_1+h of x, and if also $f'(x)$ does not become zero for any value of x between these limits, then

$$\frac{F(x_1+h)-F(x_1)}{f(x_1+h)-f(x_1)}=\frac{F'(x_1+\theta h)}{f'(x_1+\theta h)},$$

where θ is less than unity.

50. If in Taylor's series we make $x+h=0$, or $h=-x$, we get

$$f(0)=f(x)-xf'(x)+\frac{x^2}{1.2}f''(x)-\text{etc.};$$

and hence

$$f(x)=f(0)+xf'(x)-\frac{x^2}{1.2}f''(x)+\text{etc.};$$

a result which can be readily identified with Bernoulli's series, given in § 38.

51. Again, if $x=0$, Taylor's series becomes

$$f(h)=f(0)+hf'(0)+\frac{h^2}{1.2}f''(0)+\text{etc.};$$

or, as it may be written,

$$f(x)=f(0)+\frac{x}{1}f'(0)+\frac{x^2}{1.2}f''(0)+\text{etc.},$$

in which $f(0)$, $f'(0)$, $f''(0)$, etc., represent the values of $f(x)$, $f'(x)$, $f''(x)$, etc., when $x=0$.

This result is usually called Maclaurin's series, having been given in his *Fluxions* (1742). It had, however, been previously published by Stirling in his *Meth. Diff.* (1717); but neither Stirling nor Maclaurin laid any claim to the theorem as being original, both referring it to Taylor.

By substituting for $f(x)$ any of the elementary functions, such as $\sin x$, $\cos x$, $\log(1+x)$, we readily obtain their well-known expansions. It is to be noted that it is necessary in each case, for the validity of the series, to show that the remainder after n terms becomes indefinitely small when n is taken sufficiently large.

52. The application of Taylor's or of Maclaurin's theorem becomes extremely troublesome in many cases, owing to the complexity of the successive derived functions. For example, if we seek to expand $\tan x$ by Maclaurin's theorem, we have $f(x) = \tan x$, $f'(x) = \sec^2 x$, $f''(x) = 2\sec^2 x \tan x$, $f'''(x) = 2\sec^4 x + 4\sec^2 x \tan^2 x$; and the subsequent derived functions increase in complexity. Similarly in the case of other elementary functions, such as $\sec x$, $\cot x$, etc.

53. The development of $\tan x$, $\sec x$, and many other functions is much facilitated by the aid of a system of numbers, introduced by James Bernoulli. These numbers are usually arrived at as follows. It is easily seen that the expansion of $\frac{x}{e^x - 1}$, in ascending powers of x, contains no odd power of x after the first, and that the two first terms of the expansion are 1 and $-\frac{x}{2}$. Accordingly we may assume

$$\frac{x}{e^x - 1} = 1 - \frac{x}{2} + \frac{B_1}{1.2}x^2 - \frac{B_2}{1.2.3.4}x^4 + \frac{B_3}{|\underline{6}}x^6 - \dots$$

in which B_1, B_2, B_3, etc., are constants. These constants are called Bernoulli's numbers, and it can be shown without much difficulty that

$B_1 = \frac{1}{6}$, $B_2 = \frac{1}{30}$, $B_3 = \frac{1}{42}$, $B_4 = \frac{1}{30}$, $B_5 = \frac{5}{66}$, $B_6 = \frac{691}{2730}$, $B_7 = \frac{7}{6}$, etc.

The complete investigation of the method of their determination is due to Euler. See his *Calc. Diff.*, lib. ii. cap. 5.

In order to develop $\tan\theta$ by aid of them, we write it in the form

$$\tan\theta = \frac{1}{i}\left(1 - \frac{2}{1+e^{i\theta}}\right), \text{ where } i = \sqrt{-1}.$$

Hence we find

$$\tan\theta = 2^2(2^2-1)\frac{B_1\theta}{|\underline{2}} + 2^4(2^4-1)\frac{B_2\theta^3}{|\underline{4}} + 2^6(2^6-1)\frac{B_3\theta^5}{|\underline{6}}\cdots,$$

observing that

$$\frac{1}{e^x+1} = \frac{1}{e^x-1} - \frac{2}{e^{2x}-1}.$$

In like manner we get

$$\cot\theta = \frac{1}{\theta} - \frac{2^2B_1\theta}{|\underline{2}} - \frac{2^4B_2\theta^3}{|\underline{4}} - \frac{2^6B_3\theta^5}{|\underline{6}} - \text{etc.}$$

Also, since $\operatorname{cosec}\theta = \cot\theta + \tan\frac{\theta}{2}$, we get

$$\operatorname{cosec}\theta = \frac{1}{\theta} + \frac{2(2^1-1)B_1\theta}{|\underline{2}} + \frac{2(2^3-1)B_2\theta^3}{|\underline{4}} + \frac{2(2^5-1)B_3\theta^5}{|\underline{6}} + \cdots$$

For the completion of this investigation it would be necessary to consider the convergence or divergence of these series. This question would occupy too much space for treatment here.

54. The numbers $B_1, B_2, \dots$ were arrived at by James Bernoulli (*Ars conjectandi*, 1713, p. 97) in studying the summation of series of powers of the natural numbers 1, 2, 3. ...

Thus, if Sn^r represent the sum of the series

$$1^p + 2^p + 3^p \dots + (n-1)^p$$

Bernoulli proved that

$$Sn^p = \frac{n^{p+1}}{p+1} - \frac{n^p}{2} + \frac{p}{2}B_1n^{p-1} - \frac{p(p-1)(p-2)}{|\underline{4}}B_2n^{p-3} + \cdots$$

The numbers, B_1, B_2, B_3 ... were defined by Bernoulli as being the coefficients of the first power of n in the expressions for Sn^2, Sn^4, Sn^6, etc., respectively.

This series of Bernoulli may be established as follows:

If each side of the identical equation

$$1 + e^x + e^{2x} + e^{3x} \dots + e^{(n-1)x} = \frac{e^{nx}-1}{e^x-1},$$

be differentiated p times with respect to x, and we make $x = 0$ in the result, we get

$$1^p + 2^p + 3^p \dots + (n-1)^p = D^p\left(\frac{e^{nx}-1}{e^x-1}\right), \text{ when } x = 0,$$

where D stands for $\frac{d}{dx}$.

This may be written

$$Sn^p = D^p\left(\frac{e^{nx}-1}{e^x-1}\right)_{(0)}.$$

Again,

$$\frac{e^{nx}-1}{e^x-1} = \frac{e^{nx}-1}{x} \cdot \frac{x}{e^x-1}.$$

If $\phi(x) = \frac{e^{nx}-1}{x}$, and $f(x) = \frac{x}{e^x-1} = 1 - \frac{x}{2} + \frac{B_1}{1.2}x^2 - \text{etc.}$, we get by Leibnitz's theorem § 27,

$$Sn^p = f(0)\phi^{(p)}(0) + pf'(0)\phi^{p-1}(0)$$
$$+ \frac{p(p-1)}{1.2}f''(0)\phi^{p-2}(0) + \dots$$

Now it is easily seen that

$$\phi^{(k)}(0) = \frac{n^{k+1}}{k+1};$$

and hence Bernoulli's series follows immediately.

From the preceding we have

$$m\{1^{m-1} + 2^{m-1} + 3^{m-1} \dots + (z-1)^{m-1}\}$$
$$= z^m - \frac{m}{2}z^{m-1} + \frac{m(m-1)}{1.2}B_1z^{m-2} - \dots$$

The function at the right hand side of this equation has been represented by $\phi(z, m)$, and called *Bernoulli's function* of the mth order, by Professor Raabe (*Crelle*, xlii.).

Raabe has arrived at many remarkable properties of these functions, of which a few of the most elementary are here added.

$$\phi(1-z, m) = (-1)^m\phi(z, m).$$

$$\phi(\tfrac{1}{2}, 2n) = (-1)^n\frac{2^{2n}-1}{2^{2n-1}}B_n.$$

$$\frac{d}{dz}\phi(z, 2n) = 2n\phi(z, 2n-1), \text{ where } n > 1.$$

$$\frac{d}{dz}\cdot\phi(z, 2n+1) = (2n+1)\phi\{z, 2n\} + (-1)^{n-1}B_n.$$

$$\phi(z, 2n-1) = (-1)^n\frac{2\,|\underline{2n-1}}{\pi^{2n-1}}$$
$$\left\{\frac{\sin 2\pi z}{2^{2n-1}} + \frac{\sin 4\pi z}{4^{2n-1}} + \frac{\sin 6\pi z}{6^{2n-1}} + \dots\right\},$$

where $z > 0$ and < 1, and $n > 1$.

For their demonstration the reader is referred to Raabe's memoir, as also to Schlömilch's *Compendium der Höhern Analysis*.

It may be noted that the first fifteen of Bernoulli's numbers were given by Euler in his *Inst. Calc. Dif.* P. 2, ch. 5. The next sixteen were calculated by Professor Rothe, of Erlangen, and published by Ohm in *Crelle*, vol. xxii.; and thirty-one additional numbers have been recently calculated by Professor Adams, and published in the *Proceedings of the British Association* for 1877.

The fractional part in each of these numbers was calculated by Professor Adams, by aid of Von Staudt's theorem (*Crelle*, xxi.). This remarkable theorem is as follows: If 1, 2, a, a' ... $2n$, be all divisors of $2n$, and if unity be added to each so as to form the series 2, 3, $a+1$, ... $2n+1$, and of these the prime numbers 2, 3, p, p' ... be selected, the fractional part of B_n will be

$$(-1)^n\left\{\frac{1}{2} + \frac{1}{3} + \frac{1}{p} + \frac{1}{p'}\dots\right\}.$$

55. Several methods have been given for facilitating expansions by series, of which one of the most general and remarkable is that given by Arbogast in his *Calcul des Dérivations* (1800).

This is a method for expanding a function of

$$a + b\frac{x}{1} + c\frac{x^2}{1.2} + d\frac{x^3}{1.2.3} + \text{etc.}$$

in a series of ascending powers of x.

Let

$$u = a + b\frac{x}{1} + c\frac{x^2}{1.2} + d\frac{x^3}{1.2.3} + \text{etc.}$$

and suppose $\phi(u)$ represents the required function.

Also, let

$$\phi(u) = f(x) = A + B\frac{x}{1} + C\frac{x^2}{1.2} + D\frac{x^3}{1.2.3} + \text{etc.}$$
$$= f(0) + \frac{x}{1}f'(0) + \frac{x^2}{1.2}f''(0) + \text{etc.},$$

then we have $A = f(0) = \phi(a)$.

Also, writing u', u'', u''', etc. instead of

$$\frac{du}{dx}, \frac{d^2u}{dx^2}, \frac{d^3u}{dx^3}, \text{etc.},$$

we obtain, by successive differentiation of the equation

$$\begin{aligned}
f\ \ (x) &= \phi(u),\\
f'\ (x) &= \phi'(u).u',\\
f''\ (x) &= \phi'(u).u'' + \phi''(u).(u')^2,\\
f'''(x) &= \phi'(u).u''' + 3\phi''(u).u'.u'' + \phi'''(u)(u')^3,\\
f^{\text{iv}}(x) &= \phi'(u).u^{\text{iv}} + \phi''(u)[4u'.u''' + 3(u'')^2]\\
&\quad + 6\phi'''(u).(u')^2.u'' + \phi^{\text{iv}}(u).(u')^4.
\end{aligned}$$

Now, $u, u', u'', u''', \ldots$ obviously become $a, b, c, d, \ldots$ respectively, when $x=0$.

Accordingly

$$B = f'\ (0) = b\phi'(a),\ \ C = f''(0) = c\phi'(a) + b^2\phi''(a),$$
$$D = f'''(0) = d\phi'(a) + 3bc\phi''(a) + b^3\phi'''(a), \text{ etc.}$$

From the mode of formation of these terms they are seen to be each deduced from the preceding by an analogous law to that by which derived functions are deduced one from the other; and, as $f'(x), f''(x) \ldots$ are deduced from $f(x)$ by successive differentiation, so in like manner B, C, D, . . . are deduced from $\phi(u)$ by successive *derivation;* where, after differentiation, a, b, c, etc., are substituted for

$$u,\ \frac{du}{dx},\ \frac{d^2u}{dx^2}, \ldots \text{ etc.}$$

If this process of *derivation* be denoted by the letter δ, then

$$B = \delta.A,\ \ C = \delta.B,\ \ D = \delta.C, \text{ etc.}$$

From the preceding, we see that in forming the term $\delta.\phi(a)$ we take the derived function $\phi'(a)$, and multiply it by the next letter b, and similarly in other cases.

Thus $\qquad \delta.b = c, \qquad \delta.c = d, \ldots$

$$\delta.b^m = mb^{m-1}c,\quad \delta.c^m = mc^{m-1}d. \ldots$$

Also $\qquad \delta.\phi'(a)b = \phi'(a)c + \phi''(a)b^2.$

This gives the same value for C as that found before; D is derived from C in accordance with the same law; and so on. As an illustration of this method, we shall apply it to find a few terms in the expansion of

$$\sin\left(a + b\frac{x}{1} + c\frac{x^2}{1.2} + d\frac{x^3}{1.2.3} + \text{etc.}\right).$$

Here $A = \sin a$, $B = \delta.\sin a = b\cos a$,

$$\begin{aligned}
C &= \delta.b\cos a = c\cos a - b^2\sin a,\\
D &= \delta.C = d\cos a - 3bc\sin a - b^3\cos a,\\
E &= \delta.D = e\cos a - (4bd + 3c^2)\sin a - 6b^2c\cos a\\
&\quad + b^4\sin a.
\end{aligned}$$

Arbogast's theorem has been treated somewhat differently by Professor De Morgan. Thus, suppose

$$\phi(a_0 + a_1x + a_2x^2 \ldots + a_nx^n + \text{etc.}) = A_0 + A_1x + A_2x^2 \ldots + A_nx^n + \text{etc.};$$

then if we differentiate with respect to a_n, we have

$$\phi'(a_0 + a_1x \ldots + a_nx^n + \text{etc.})x^n = \frac{dA_0}{da_n} + \frac{dA_1}{da_n}x \cdots + \frac{dA_n}{da_n}x^n + \text{etc.}$$

Hence we infer that, if m be less than n, we have $\dfrac{dA_m}{da_n} = 0$,

also $\qquad \dfrac{dA_m}{da_m} = \dfrac{dA_{m-1}}{da_{m-1}} = \ldots = \dfrac{dA_0}{da_0} = \phi'(a_0),$

and $\qquad \dfrac{dA_{m+n}}{da_m} = \dfrac{da_n}{da_0}$, etc.

The values of $A_1, A_2, \ldots A_n$ can be hence calculated (see De Morgan's *Differential and Integral Calculus*, arts. 214–220).

56. Lagrange, in addition to having been the first to place Taylor's series on a satisfactory basis, also enlarged the powers of analysis by a remarkable theorem which contains Taylor's as a particular case. This, which is commonly called Lagrange's Formula, first appeared in 1768 in the Berlin memoirs, and may be stated as follows:—

If z be connected with x and y by the equation

$$z = x + y\phi(z),$$

then the expansion, in ascending powers of y, of any function $F(z)$ may be thus written:—

$$F(z) = F(x) + \frac{y}{1}\phi(x)F'(x) + \frac{y^2}{1.2}\frac{d}{dx}\left\{[\phi(x)]^2F'(x)\right\}$$
$$\ldots + \frac{y^n}{\underline{|n}}\left(\frac{d}{dx}\right)^{n-1}\left\{[\phi(x)]^nF'(x)\right\}\ldots$$

This result can be deduced from Maclaurin's theorem, as was shown by Laplace, thus:—

Let $u = F(x)$, and we may write

$$u = u_0 + y\left(\frac{du}{dy}\right)_0 + \frac{y^2}{1.2}\left(\frac{d^2u}{dy^2}\right)_0 \ldots + \frac{y^n}{\underline{|n}}\left(\frac{d^nu}{dy^n}\right)_0 \ldots$$

where $\left(\dfrac{du}{dy}\right)_0, \left(\dfrac{d^2u}{dy^2}\right)_0 \ldots$ represent the values of $\dfrac{du}{dy}, \dfrac{d^2u}{dy^2} \ldots$ when we make $y = 0$ after differentiation.

We plainly have $u_0 = F(x)$.

Also, it is easily seen by differentiation that

$$\frac{dz}{dy} = Z\frac{dz}{dx},\ \ \frac{du}{dy} = Z\frac{du}{dx},$$

writing Z for $\phi(z)$.

Again $\qquad \dfrac{d}{dy}\left(\dfrac{du}{dy}\right) = \dfrac{d}{dy}\left(Z\dfrac{du}{dx}\right) = \dfrac{d}{dx}\left(Z\dfrac{du}{dy}\right) = \dfrac{d}{dx}\left(Z^2\dfrac{du}{dx}\right) \ldots$

Hence we can deduce in like manner

$$\frac{d^3u}{dy^3} = \left(\frac{d}{dx}\right)^2\left(Z^3\frac{du}{dx}\right);$$

and in general

$$\frac{d^nu}{dy^n} = \left(\frac{d}{dx}\right)^{n-1}\left(Z^n\frac{du}{dx}\right).$$

If now we suppose $y = 0$, since Z reduces to $\phi(x)$, and $\dfrac{du}{dx}$ to $F'(x)$, we get

$$\left(\frac{du}{dy}\right)_0 = \phi(x)F'(x),\ \left(\frac{d^2u}{dy^2}\right)_0 = \frac{d}{dx}\left\{[\phi(x)]^2F'(x)\right\}\ldots$$

from which the series immediately follows.

For example, let $z + x + \dfrac{y}{2}(z^2 - 1)$;

then the expansion of z becomes

$$z = x + \frac{y}{2}(x^2 - 1) + \frac{1}{1.2}\left(\frac{y}{2}\right)^2\frac{d}{dx}(x^2 - 1)^2 \ldots$$
$$+ \frac{1}{\underline{|n}}\left(\frac{y}{2}\right)^n\left(\frac{d}{dx}\right)^{n-1}(x^2 - 1)^n \ldots$$

Again, from our equation we get

$$z = \frac{1}{y} - \frac{\sqrt{1 - 2xy + y^2}}{y}.$$

Hence $\qquad \dfrac{dz}{dx} = (1 - 2xy + y^2)^{-\frac{1}{2}}.$

Consequently we have

$$(1 - 2xy + y^2)^{-\frac{1}{2}} = 1 + \frac{y}{2}\frac{d}{dx}(x^2 - 1) \ldots$$
$$+ \frac{1}{\underline{|n}}\left(\frac{y}{2}\right)^n\left(\frac{d}{dx}\right)^n(x^2 - 1)^n \ldots$$

If we write this expansion in the form

$$(1 - 2xy + y^2)^{-\frac{1}{2}} = 1 + Xy + X_2y^2 \ldots + X_ny^n \ldots$$

we have[1] $\qquad X_n = \dfrac{1}{\underline{|n}}\dfrac{1}{2^n}\left(\dfrac{d}{dx}\right)^n(x^2 - 1)^n.$

The class of functions represented by X_n was extensively studied by Legendre, to whose works the reader is referred for further development.

An expression for the remainder in Lagrange's series in the form of a definite integral will be given further on.

57. Taylor's series admits of ready extension to two or more variables; thus, if we change x into $x + h$ in the equation $u = \phi(x,y)$, we get by Taylor's theorem,

$$\phi(x + h, y) = u + h\frac{du}{dx} + \frac{h^2}{1.2}\frac{d^2u}{dx^2} + \frac{h^3}{1.2.3}\frac{d^3u}{dx^3} + \text{etc.}$$

If now we change y into $y + k$,

$$u \text{ or } \phi(x, y) \text{ becomes } u + k\frac{du}{dy} + \frac{k^2}{1.2}\frac{d^2u}{dy^2} + \text{etc.}$$

$$h\frac{du}{dx} \text{ becomes } h\frac{du}{dx} + hk\frac{d^2u}{dxdy} + h\frac{k^2}{1.2}\frac{d^3u}{dxdy^2} + \text{etc.};$$

. . . .

and accordingly we have

$$\phi(x + h, y + k) = u + h\frac{du}{dx} + k\frac{du}{dy}$$
$$+ \frac{h^2}{1.2}\frac{d^2u}{dx^2} + hk\frac{d^2u}{dxdy} + \frac{k^2}{1.2}\frac{d^2u}{dy^2} + \text{etc.}$$

---

[1] This remarkable expression for X_n is due to Jacobi (*Crelle*, ii. p. 223).

By aid of Lagrange's theorem in § 46 we can obtain an expression for the remainder of the series.

In like manner, if $u = \phi(x,y,z)$, we get

$$\phi(x+h, y+k, z+l) = u + h\frac{du}{dx} + k\frac{du}{dy} + l\frac{du}{dz} + \frac{h^2}{1\,.\,2}\frac{d^2u}{dx^2}$$

$$+\frac{k^2}{1\,.\,2}\frac{d^2u}{dy^2} + \frac{l^2}{1\,.\,2}\frac{d^2u}{dz^2} + hk\frac{d^2u}{dxdy} + kl\frac{d^2u}{dydz} + lh\frac{d^2u}{dzdx} + \text{etc.}$$

The method can be readily extended to a function of any number of variables.

1. As an example of Maclaurin's theorem, the first three terms in the expansion of tan x are $x + \frac{x^3}{3} + \frac{2x^5}{15}$.

(2) Prove that

$$\tan^{-1}(x+h) = \tan^{-1}x + h\sin z\frac{\sin z}{1} - (h\sin z)^2\frac{\sin 2z}{2}$$

$$+ (h\sin z)^3\frac{\sin 3z}{3} - \cdots \text{etc.}$$

where $z = \cot^{-1}x$.

(3) If $x\frac{d^2y}{dx^2} + \frac{dy}{dx} + y = 0$, y may be easily expanded in terms of x by the method of indeterminate coefficients.

(4) By similar methods the first four terms in the expansion of $(1+x)^{\frac{1}{x}}$ in ascending powers of x are found to be

$$\left(1 - \frac{x}{2} + \frac{11x^2}{24} - \frac{7x^3}{16}\right)e.$$

(5) Find the development of $\frac{x\sin 3x}{\sin x\sin 2x}$ in ascending powers of x, the coefficients being expressed in Bernoulli's numbers.

(6) Prove that Legendre's function X_n satisfies the differential equation

$$(1-x^2)\frac{d^2X_n}{dx^2} - 2x\frac{dX_n}{dx} + n(n+1)X_n = 0;$$

also that

$$\frac{dX_{n+1}}{dx} = (2n+1)X_n + (2n-3)X_{n-2} + (2n-7)X_{n-4} + \cdots$$

Indeterminate Forms.

58. Another important application of the infinitesimal method is to the determination of the true or limiting values of indeterminate expressions.

For example, if the fraction $\frac{f(x)}{\phi(x)}$ becomes of the form $\frac{0}{0}$, or $\frac{\infty}{\infty}$, when $x = a$, the fraction is said to become indeterminate for that value of x.

In fact, the method of the evaluation of indeterminate forms may be regarded as the foundation of the differential calculus, since the determination of the derived function of any expression $f(x)$ reduces to finding the limiting value of $\frac{f(x+h) - f(x)}{h}$ when $h = 0$.

We shall first consider the case where $f(a) = 0$, and $\phi(a) = 0$. Here the true value of $\frac{f(a)}{\phi(a)}$ is that of $\frac{f(a+h)}{\phi(a+h)}$ when h is evanescent.

But
$$\frac{f(a+h)}{\phi(a+h)} = \frac{f(a) + hf'(a+\theta h)}{\phi(a) + h\phi'(a+\theta_1 h)} = \frac{f'(a+\theta h)}{\phi'(a+\theta_1 h)}$$

$$= \frac{f'(a)}{\phi'(a)} \text{ when } h = 0.$$

Hence the limiting value of the fraction is in this case represented by $\frac{f'(a)}{\phi'(a)}$.

Again, if $\frac{f'(a)}{\phi'(a)}$ be also of the form $\frac{0}{0}$, its true value is that of $\frac{f''(a)}{\phi''(a)}$; and so on.

In general, if the order of the lowest derived functions which do not both vanish is n, then the true value of $\frac{f(a)}{\phi(a)}$ is that of $\frac{f^{(n)}(a)}{\phi^{(n)}(a)}$.

For example, the fraction $\frac{x^a\sin ay - y^a\sin ax}{\tan ay - \tan ax}$ is of the form $\frac{0}{0}$ when $x = y$, to find its true value.

Here $f(x) = x^a\sin ay - y^a\sin ax$, $\phi(x) = \tan ay - \tan ax$,
$\therefore f'(x) = ax^{a-1}\sin ay - ay^a\cos ax$, $\phi'(x) = -a\sec^2 ax$,
accordingly the required value is represented by

$$\frac{f'(y)}{\phi'(y)} = y^{a-1}(y\cos ay - \sin ay)\cos^2 ay.$$

59. Again, to find the true value of $\frac{f(a)}{\phi(a)}$, if $f(a) = \infty$, $\phi(a) = \infty$.

Here
$$\frac{f(x)}{\phi(x)} = \frac{\frac{1}{\phi(x)}}{\frac{1}{f(x)}}, \text{ which is of the form } \frac{0}{0}, \text{ when } x = a.$$

Hence, by the former case, its limiting value is that of

$$\frac{\phi'(x)}{f'(x)}\left\{\frac{f(x)}{\phi(x)}\right\}^2.$$

Suppose A to represent the limiting value in question and we have

$$A = \frac{\phi'(a)}{f'(a)}A^2, \text{ or } A = \frac{f'(a)}{\phi'(a)}.$$

Accordingly the true value of the indeterminate form $\frac{\infty}{\infty}$ is found in the same manner as that of the form $\frac{0}{0}$.

In the preceding, in dividing both sides of our equation by A, we have assumed that A is neither zero nor infinite. It can, however, be easily shown that the true value in either of these cases is still that of $\frac{f'(a)}{\phi'(a)}$.

60. Again, the expression $f(x) \times \phi(x)$ becomes indeterminate for any value of x which makes one of its factors zero and the other infinite. The expression, however, is readily reduced to the form $\frac{0}{0}$; for, if $f(a) = 0$, and $\phi(a) = \infty$, we have

$$f(a) \times \phi(a) = f(a) \div \frac{1}{\phi(a)}, \text{ which is of the form } \frac{0}{0}.$$

Also, if the true value of $\frac{f(a)}{\phi(a)}$ be unity when $\phi(a) = \infty$, then

$$f(a) - \phi(a) = \left\{\frac{f(a)}{\phi(a)} - 1\right\}\phi(a) = \left\{\frac{f(a)}{\phi(a)} - 1\right\} \div \frac{1}{\phi(a)}.$$

This is of the form $\frac{0}{0}$, and its true value can in general be found as above. By this means the true value of $f(x) - \phi(x)$ when $f(x) = \infty$, and $\phi(x) = \infty$ can be found.

61. The expression u^v becomes indeterminate in some cases; for suppose $y = u^v$, then $\log y = v\log u$. This latter product becomes indeterminate whenever one of its factors is zero and the other infinite.

(1) Let $v = 0$, and $\log u = \pm\infty$; the latter equation requires either $u = \infty$, or $u = 0$. Consequently u^v becomes indeterminate for either of the forms 0^0 or ∞^0.

(2) Let $v = \pm\infty$, $\log u = 0$; the latter equation gives $u = 1$, and the corresponding indeterminate forms are 1^{∞} or $1^{-\infty}$.

62. In many cases the true value of an indeterminate form can be best determined by ordinary algebra or trigonometry. Thus, for example, the expression

$$\frac{\sqrt{a^2 + ax + x^2} - \sqrt{a^2 - ax - x^2}}{\sqrt{a+x} - \sqrt{a-x}}$$

is of the form $\frac{0}{0}$ when $x = 0$. To find its true value we multiply by the *complementary* surds, when the expression becomes

$$\frac{\sqrt{a+x} + \sqrt{a-x}}{\sqrt{a^2 + ax + x^2} + \sqrt{a^2 - ax - x^2}} \times \frac{ax + x^2}{x},$$

the true value of which is plainly $\sqrt{a}$, when $x = 0$.

63. The differential calculus was applied for the first time to finding the true value of an indeterminate form by John Bernoulli, in the *Acta Eruditorum*, 1704, when studying the problem of drawing the tangents at a multiple point on a curve. This problem, as stated already in the Introduction, was started by Rolle, as a crux for the advocates of the differential calculus. It may be here remarked that the determination of the tangents at a multiple point is generally much simpler by Cartesian co-ordinate geometry than by the method of the differential calculus.

A few elementary examples are added of the different classes of indeterminate forms here given.

(1) $$u = \left|\frac{e^{mx} - e^{ma}}{(x-a)^r}\right|, \text{ when } x = a.$$

Here $f(x) = e^{mx} - e^{ma}$, $\phi(x) = (x-a)^r$,
$\therefore f'(x) = me^{mx}$, $\phi'(x) = r(x-a)^{r-1}$

Accordingly, when $r>1$, $u=\infty$; when $r=1$, $u=me^{ma}$; when $r<1$, $u=0$.

(2) $$u=\frac{\cos x\theta-\cos n\theta}{(n^2-x^2)^r}, \text{ when } x=n.$$

For $r>1$, $u=\infty$; for $r=1$, $u=-\frac{\theta\sin n\theta}{2}$; and for $r<1$, $u=0$.

(3) $$u=\frac{x^2+2\cos x-2}{\tan^4 x}, \text{ when } x=0.$$

Since $\frac{x}{\tan x}=1$ when $x=0$, the true value of u, in this case, is the same as that of $\frac{x^2+2\cos x-2}{x^4}$, and is easily seen to be $\frac{1}{12}$.

(4) $$u=\frac{x^n}{e^x}, \text{ when } x=\infty.$$

Here $u=\left(\frac{\frac{x}{x}}{e^{n}}\right)^n$; but the true value of $\frac{\frac{x}{x}}{e^{n}}$, when $x=\infty$, is easily seen to be zero, consequently the true value of u is also zero.

(5) $$u=\left(1+\frac{a}{x}\right)^x, \text{(1) when } x=0, \text{ and (2) when } x=\infty.$$

The true values are (1) $u=1$; (2) $u=e^a$.

(6) $$\sqrt{x^2+ax}-\sqrt{x^2+bx}, \text{ when } x=\infty.$$

This is of the form $\infty-\infty$; its true value, however, is that of

$$\frac{(a-b)x}{\sqrt{x^2+ax}+\sqrt{x^2+bx}}=\frac{a-b}{\sqrt{1+\frac{a}{x}}+\sqrt{1+\frac{b}{x}}}=\frac{a-b}{2}.$$

(7) $u=\frac{(x\sin^2\theta+y\cos^2\theta)^n-x^n}{x^n-y^n}$, when $x=y$. True value, $\sin^2\theta$.

(8) $\frac{x\sin(\sin x)-\sin^2 x}{\sin^6 x}$, when $x=0$. True value $\frac{1}{18}$.

(9) $$x\left(1-a^{\frac{1}{x}}\right), \text{ when } x=\infty.$$

This is equivalent to $\frac{1-a^z}{z}$ when $z=0$, and accordingly its true value is $-\log a$.

(10) $\frac{\sqrt{x}-\sqrt{\sin x}}{\sqrt{x^5}}$, when $x=0$. True value, $\frac{1}{12}$.

Maxima and Minima.

64. We have seen in the introduction that the question of finding the greatest and least values of an expression was, in the hands of Fermat, one of the first applications of the method of infinitesimals. We have also seen that the principle of his method had been previously stated correctly by Kepler, and is the same as that obtained by the differential calculus. We now proceed to a more general investigation on maxima and minima.

Let u represent the function, and x the variable, and suppose we have $u=f(x)$.

Let a be a value of x corresponding to a *maximum* or a *minimum* value of u, then for a *maximum* we must have

$$f(a)>f(a+h), \text{ and } f(a)>f(a-h),$$

for small values of h; and for a *minimum*,

$$f(a)<f(a+h), \text{ and } f(a)<f(a-h).$$

Accordingly, in either case, $f(a+h)-f(a)$ and $f(a-h)-f(a)$ must have the same sign, h being small.

But we have already seen that

$$f(a+h)-f(a)=hf'(a)+\frac{h^2}{1\,.\,2}f''(a+\theta h),$$

$$f(a-h)-f(a)=-hf'(a)+\frac{h^2}{1\,.\,2}f''(a-\theta h),$$

where θ is >0 and <1.

Now, when $f''(a)$ is finite, it is plain that $f(a+h)-f(a)$ and $f(a-h)-f(a)$ cannot have both the same sign, when h is very small, unless $f'(a)=0$.

Accordingly, the roots of the equation $f'(x)=0$ furnish in general the values of x for which $f(x)$ has a maximum or a minimum value.

Also we have in this case—

$$f(a+h)-f(a)=\frac{h^2}{1\,.\,2}f''(a+\theta h),$$

$$f(a-h)-f(a)=\frac{h^2}{1\,.\,2}f''(a-\theta h).$$

Consequently, when $f''(a)$ is *negative*, the corresponding value of $f(a)$ is a *maximum*; and when $f''(a)$ is *positive*, $f(a)$ is a *minimum*.

If, however, $f''(a)$ vanishes, along with $f'(a)$, it is readily seen that the corresponding value of u is neither a maximum nor a minimum unless $f'''(a)$ also vanish.

In general, let $f^{(n)}(a)$ be the first derived function that does not vanish; then, if n be odd, the corresponding value of u is neither a maximum nor a minimum; but if n be even, the corresponding value is a maximum when $f^{(n)}(a)$ is negative and a minimum when it is positive.

These rules for distinguishing between maxima and minima were first given correctly by Maclaurin, in his *Fluxions*, ch. ix.

If the equation $f'(x)=0$ has no real solution, then $f(x)$ has no maximum or minimum value, and consequently is capable of having all possible values from $+\infty$ to $-\infty$.

We shall illustrate the preceding theory by applying it to a few simple cases.

(1) $$u=x^2+ax+b.$$

Here $$\frac{du}{dx}=2x+a=0, \therefore x=-\frac{a}{2}.$$

Again $\frac{d^2u}{dx^2}=2$. Since this is a positive quantity, the function is a *minimum* when $x=-\frac{a}{2}$. Its minimum value is $b-\frac{a^2}{4}$; as is also evident because

$$u=\left(x+\frac{a}{2}\right)^2+b-\frac{a^2}{4}.$$

(2) $$u=\frac{ax^2+2bx+c}{a'x^2+2b'x+c'}.$$

Here $$ax^2+2bx+c=u(a'x^2+2b'x+c').$$

Differentiate both sides, and, since $\frac{du}{dx}=0$ for a maximum or a minimum, we have

$$ax+b=(a'x+b')u.$$

Hence the roots of the quadratic

$$(ab'-ba')x^2+(ac'-ca')x+bc'-cb'=0$$

give the required solutions.

The corresponding values of u are given by the quadratic

$$u^2(b'^2-a'c')+u(ac'+ca'-2bb')+b^2-ac=0.$$

If the roots of the quadratic in x be imaginary, the proposed fraction has no maximum or minimum value. When the roots are real, the fraction has one maximum and one minimum value. These can be easily distinguished in any particular case. It is easily seen that to the greater root corresponds a *minimum*, and to the lesser a *maximum* value of the fraction, in general.

(3) $$u=\tan x-x.$$

Here $$\frac{du}{dx}=\sec^2 x-1, \quad \frac{d^2u}{dx^2}=2\sec^2 x\tan x,$$

$$\frac{d^3u}{dx^3}=2\sec^4 x-4\sec^2 x\tan^2 x.$$

Hence, for a maximum or a minimum we have $\sec^2 x=1$,

$\therefore$ $\tan x=0$; consequently $\frac{d^2u}{dx^2}=0$, and $\frac{d^3u}{dx^3}=2$.

Accordingly the proposed has neither a maximum nor a minimum value.

(4) $$u=\frac{x}{1+x^2}.$$

The fraction $\frac{x}{1+x^2}$ is a maximum or a minimum according as $\frac{1+x^2}{x}$ is a minimum or a maximum, as is evident from the principle that, when u is a maximum, $\frac{1}{u}$ is a minimum.

But $x+\frac{1}{x}$ is a maximum or a minimum when $\frac{1}{x^2}=1$, or $x=\pm 1$.

Again, it is easily seen that the upper sign corresponds to a *minimum*, and the lower to a *maximum*. We accordingly conclude that $\frac{1}{2}$ is the maximum value of $\frac{x}{1+x^2}$, and $-\frac{1}{2}$ its minimum value.

(5) The expression $u=x^x$ has its critical value when $x=\frac{1}{e}$.

65. Again, to find the maximum or minimum values of u, if $u=f(z)$, where $z=\phi(x)$.

Here $$\frac{du}{dx} = f'(z)\phi'(x),$$
and consequently the solutions of the problem are—(1) those given by $\phi'(x) = 0$, *i. e.*, the maximum and minimum of z; (2) those given by $f'(z) = 0$.

In many cases the values of z are restricted by the conditions of the problem to lie between given limits; accordingly in such cases no root of $f'(z) = 0$ can furnish a real solution unless it lies between the given limiting values. This result will be illustrated in the following examples.

1. *To find the maximum and minimum perpendicular from the focus on the tangent to an ellipse, the perpendicular* p *being expressed in terms of the radius vector* r.

The expression for the perpendicular p, in terms of the radius vector, is
$$p^2 = \frac{b^2 r}{2a - r};$$
$$\therefore \quad p\frac{dp}{dr} = \frac{ab^2}{(2a - r)^2}.$$
Accordingly $\frac{dp}{dr} = 0$ gives $r = \pm\infty$; but these values are inadmissible, since r is restricted to lie between the values $a(1 + e)$ and $a(1 - e)$.

Consequently the only maximum and minimum values of p are those which correspond to the maximum and minimum values of r; *i. e.*, $a(1 + e)$ and $a(1 - e)$.

2. *To find in an ellipse the conjugate diameters whose sum is a maximum or a minimum.*

If r and r' be two conjugate diameters, we have $r^2 + r'^2 = a^2 + b^2$,
$$\therefore \quad u = r + \sqrt{a^2 + b^2 - r^2}.$$

The solutions accordingly are given,—(1) by the maximum and minimum values of r, and (2) by the equation
$$1 - \frac{r}{\sqrt{a^2 + b^2 - r^2}} = 0.$$

The latter gives the equiconjugate diameters, the former the axes of the ellipse. It is easily seen that the former solution gives a *maximum*, the latter a *minimum;* as is also readily shown otherwise.

3. *To find the position of a planet when brightest, its orbit and that of the earth being supposed circular, and to lie in the same plane.*

Let S, E, P (fig. 4) be the positions of the centres of the sun, earth, and planet respectively. Let ACBD represent the section of the planet made by the plane SEP. Draw AB perpendicular to SP, and CD perpendicular to PE. Then ADB represents the illuminated half of the planet, and CBD the half visible from the earth. Accordingly the portion of the illuminated surface turned towards the earth is contained between two planes drawn respectively through AB and CD perpendicular to SPE. This surface is projected into a crescent, the breadth of which is proportional to the versine of BPD, or to $1 + \cos$ EPS.

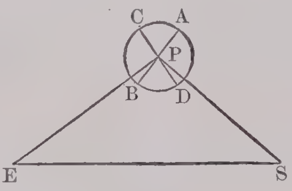

Fig. 4.

Again, the brightness, depending on its distance from the earth and its position respecting the sun conjointly, will vary as
$$\frac{1 + \cos \text{EPS}}{\text{PE}^2}.$$
Let $a = \text{ES}$, $\quad b = \text{PS}$, $\quad x = \text{PE}$; then
$$\cos \text{EPS} = \frac{x^2 + b^2 - a^2}{2bx}, \quad \therefore \quad \frac{1 + \cos \text{EPS}}{\text{PE}^2} = \frac{x^2 + 2bx + b^2 - a^2}{2bx^3}.$$

Hence, neglecting a constant multiplier, we have
$$u = \frac{1}{x} + \frac{2b}{x^2} - \frac{a^2 - b^2}{x^3}.$$

Accordingly, the solutions of the problem correspond to—

(1) The *maximum* and *minimum* values of x, *i. e.*, $a + b$ and $a - b$;

(2) The roots of the equation $\frac{du}{dx} = 0$, or of
$$x^2 + 4bx - 3(a^2 - b^2) = 0;$$
whence we get $$x = \sqrt{3a^2 - b^2} - 2b;$$
neglecting the negative root, which is inadmissible.

If $b > a$, $\sqrt{3a^2 + b^2} - 2b$ is negative, and accordingly this gives no solution in the case of an exterior planet.

For an interior planet we have $a > b$; and it remains to determine whether $\sqrt{3a^2 + b^2} - 2b$ lies between the maximum and minimum values of x, *i.e.*, between $a + b$ and $a - b$.

Since $a > b$, it is immediately seen that $\sqrt{3a^2 + b^2} - 2b$ is $> a - b$. The remaining condition requires
$$a + b > \sqrt{3a^2 + b^2} - 2b, \text{ or } a + 3b > \sqrt{3a^2 + b^2},$$
$$i.\,e., a^2 + 6ab + 9b^2 > 3a^2 + b^2, \text{ or } 4b^2 + 3ab > a^2.$$

Hence we easily find $b > \frac{a}{4}$. We accordingly infer that this gives no real solution for a planet nearer to the sun than one-fourth of the earth's distance. When this condition is fulfilled it is readily shown that the corresponding solution is a *maximum*, and that the solutions corresponding to $x = a + b$ and $x = a - b$ are both *minimum* solutions.

66. Many problems of maxima and minima contain two variables, which are connected by an equation of condition. Thus, to find the maximum or minimum values of $\phi(x, y)$, where x and y are connected by the relation
$$f(x, y) = 0.$$
Here we have
$$\frac{d\phi}{dx} + \frac{d\phi}{dy}\frac{dy}{dx} = 0, \frac{df}{dx} + \frac{df}{dy}\frac{dy}{dx} = 0.$$
Accordingly the maximum and minimum solutions are obtained from the simultaneous equations
$$\frac{d\phi}{dx} \cdot \frac{df}{dy} - \frac{d\phi}{dy}\frac{df}{dx} = 0, \text{ and } f(x, y) = 0.$$
More generally, if $n + 1$ variables, $x, x_1, x_2 \ldots x_n$, be connected by n equations
$$\text{F}_1 = 0, \text{F}_2 = 0, \ldots \text{F}_n = 0,$$
and it be proposed to find the maximum or minimum value of a given function $f(x, x_1, x_2 \ldots x_n)$ of these variables, we have, by differentiation, the equations
$$\frac{df}{dx}dx + \frac{df}{dx_1}dx_1 + \ldots + \frac{df}{dx_n}dx_n = 0,$$
$$\frac{d\text{F}_1}{dx}dx + \frac{d\text{F}_1}{dx_1}dx_1 + \ldots + \frac{d\text{F}_1}{dx_n}dx_n = 0,$$
$$\cdots\cdots\cdots\cdots\cdots\cdots$$
$$\frac{d\text{F}_n}{dx}dx + \frac{d\text{F}_n}{dx_1}dx_1 + \ldots + \frac{d\text{F}_n}{dx_n}dx_n = 0,$$
which give, on elimination, the determinant equation
$$\begin{vmatrix} \frac{df}{dx} & \frac{df}{dx_1} & \ldots & \frac{df}{dx_n} \\ \frac{d\text{F}_1}{dx} & \frac{d\text{F}_1}{dx_1} & \ldots & \frac{d\text{F}_1}{dx_n} \\ \cdot & \cdot & \cdot & \cdot \\ \frac{d\text{F}_n}{dx} & \frac{d\text{F}_n}{dx_1} & \ldots & \frac{d\text{F}_n}{dx_n} \end{vmatrix} = 0.$$
This joined with the given equations determines the system of values of $x, x_1, x_2 \ldots x_n$ for which the function may have a maximum or a minimum value.

Maxima and Minima for Functions of two or more Independent Variables.

67. Let $u = \phi(x, y)$, then, as in § 64, if x and y are independent, the maximum or minimum value of u must satisfy the equations
$$\frac{du}{dx} = 0, \text{ and } \frac{du}{dy} = 0.$$
Suppose x_0 and y_0 to be values of x and y which satisfy these equations; then, in order that they should correspond to a real maximum or minimum value of u, the expression
$$\phi(x_0 + h, y_0 + k) - \phi(x_0, y_0)$$
must have the same sign for all small values of h and k, as in the former case.

Again let A, B, C be the values of $\frac{d^2u}{dx^2}, \frac{d^2u}{dxdy}, \frac{d^2u}{dy_2}$ respectively, when $x = x_0$ and $y = y_0$. Then, by § 57,
$$\phi(x_0 + h, y_0 + k) - \phi(x_0, y_0) = \tfrac{1}{2}(\text{A}h^2 + 2\text{B}hk + \text{C}k^2) + \text{etc.}$$
But, when h and k are very small, the remainder of the expansion is, in general, very small in comparison with $\text{A}h^2 + 2\text{B}hk + \text{C}k^2$; and consequently the sign of

$$\phi(x_0 + h, y_0 + k) - \phi(x_0, y_0)$$

depends on that of

$$\mathrm{A}h^2 + 2\mathrm{B}hk + \mathrm{C}k^2, \text{ i.e., of } \frac{(\mathrm{A}h + \mathrm{B}k)^2 + k^2(\mathrm{AC} - \mathrm{B}^2)}{\mathrm{A}}.$$

Now, in order that the latter should have the same sign for all small values of h and k, $\mathrm{AC} - \mathrm{B}^2$ must not be negative; *i. e.*, $\frac{d^2u}{dx^2} \cdot \frac{d^2u}{dy^2} - \left(\frac{d^2u}{dxdy}\right)^2$ must not be negative. When this condition holds, the resulting value of u is a maximum when A is negative, and a minimum when A is positive. The necessity for this condition was first established by Lagrange.

In the particular case where $\mathrm{A} = 0$, $\mathrm{B} = 0$, $\mathrm{C} = 0$, then for a real maximum or minimum it is necessary that all the terms of the third degree in h and k in the expansion of $\phi(x_0 + h, y_0 + k)$ should also vanish, and that the quantity of the fourth degree should preserve the same sign for all values of h and k.

The preceding discussion admits of a simple geometrical interpretation by considering the surface represented by the equation $z = \phi(x, y)$; since it reduces to finding the points on the surface of maximum or minimum distance from the plane of xy.

68. Next let $u = \phi(x, y, z)$, where x, y, z are independent variables. Here, as before, if x_0, y_0, z_0 correspond to a maximum or a minimum value of u they must satisfy the equations

$$\frac{du}{dx} = 0, \quad \frac{du}{dy} = 0, \quad \frac{du}{dz} = 0.$$

Accordingly we have

$$\phi(x_0 + h, y_0 + k, z_0 + l) - \phi(x_0, y_0, z_0)$$
$$= \tfrac{1}{2}(\mathrm{A}h^2 + \mathrm{B}k^2 + \mathrm{C}l^2 + 2\mathrm{F}kl + 2\mathrm{G}hl + 2\mathrm{H}hk) + \text{etc.},$$

where A, B, C, F, G, H represent the values of

$$\frac{d^2u}{dx^2}, \frac{d^2u}{dy^2}, \frac{d^2u}{dz^2}, \frac{d^2u}{dydz}, \frac{d^2u}{dzdx}, \frac{d^2u}{dxdy}$$

respectively, when $x = x_0$, $y = y_0$, $z = z_0$.

Now, as in the former case, in order that u should have a maximum or a minimum value, it is necessary that

$$\mathrm{A}h^2 + \mathrm{B}k^2 + \mathrm{C}l^2 + 2\mathrm{F}kl + 2\mathrm{G}lh + 2\mathrm{H}hk$$

should preserve the same sign for all small values of h, k, and l.

If we multiply by A, this expression may be written

$$(\mathrm{A}h + \mathrm{H}k + \mathrm{G}l)^2 + (\mathrm{AB} - \mathrm{H}^2)k^2 + 2(\mathrm{AF} - \mathrm{GH})kl$$
$$+ (\mathrm{AC} - \mathrm{G}^2)l^2.$$

Consequently the sum of the last three terms must be always positive.

Hence, in order that the expression in question should be positive for all small values of h, k, and l, we must have

$$\mathrm{A} > 0, \quad \begin{vmatrix} \mathrm{A}, & \mathrm{H} \\ \mathrm{H}, & \mathrm{B} \end{vmatrix} > 0, \quad \begin{vmatrix} \mathrm{A}, & \mathrm{H}, & \mathrm{G} \\ \mathrm{H}, & \mathrm{B}, & \mathrm{F} \\ \mathrm{G}, & \mathrm{F}, & \mathrm{C} \end{vmatrix} > 0.$$

This result is also due to Lagrange.

The corresponding conditions for the case of four or more independent variables can be likewise determined, and are readily expressed in the form of a series of determinants. See *Quarterly Journal of Mathematics*, 1872, p. 48.

(1) To find the maximum or minimum value of the function

$$ax^2 + 2hxy + by^2 + 2gx + 2fy + c.$$

It is easily seen that when $h^2 > ab$, there is neither a maximum nor a minimum value. When $ab > h^2$, and $a > c$, we obtain, as the minimum value,

$$\begin{vmatrix} a, & h, & g \\ h, & b, & f \\ g, & f, & c \end{vmatrix} \div \begin{vmatrix} a, & h \\ h, & b \end{vmatrix}.$$

(2) Similarly it can be shown that the maxima or minima values of

$$\frac{ax^2 + by^2 + 2hxy + 2gx + 2fy + c}{a'x^2 + b'y^2 + 2h'xy + 2g'x + 2f'y + c'}$$

are the roots of the cubic equation

$$\begin{vmatrix} a - a'u & h - h'u & g - g'u \\ h - h'u & b - b'u & f - f'u \\ g - g'u & f - f'u & c - c'u \end{vmatrix} = 0.$$

(3) Of all triangular pyramids standing on a given triangular base, and of given altitude, find that whose surface is the least.

Tangents and Normals to Curves.

69. The infinitesimal calculus furnishes, as we have seen, a general method of finding the tangent at any point in a curve whose equation is given. For example, let $y = f(x)$ be the equation, in Cartesian co-ordinates, to any curve; and suppose (x, y), (x_1, y_1) to be the co-ordinates of two points P,Q in the curve (Fig. 5), and (X, Y) those of any point on the line passing through these points, then the equation of the line is

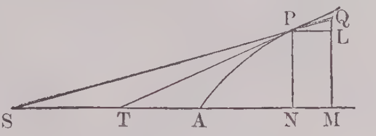

Fig. 5.

$$\mathrm{Y} - y = (\mathrm{X} - x)\frac{y_1 - y}{x_1 - x}.$$

If now the point Q be supposed to approach P, and ultimately to coincide with it, the line becomes the tangent PT at the point P, and its equation becomes

$$\mathrm{Y} - y = (\mathrm{X} - x)\frac{dy}{dx}.$$

For example, in the curve represented by

$$x^m = ay^n,$$

we have

$$\frac{dy}{dx} = \frac{my}{nx};$$

and the equation of the tangent at the point x, y is

$$m\frac{\mathrm{X}}{x} - n\frac{\mathrm{Y}}{y} = m - n.$$

This furnishes a simple construction for the tangent at any point on a parabolic curve. (Compare Ricci's construction given in the Introduction, p. 7.)

If the equation of the curve be given in the form $u = f(x, y) = 0$,

we have
$$\frac{du}{dx} + \frac{du}{dy}\frac{dy}{dx} = 0,$$

and the equation of the tangent is

$$(\mathrm{X} - x)\frac{du}{dx} + (\mathrm{Y} - y)\frac{du}{dy} = 0.$$

70. Again, the normal at the point (x, y), being perpendicular to the tangent, has for its equation

$$\frac{du}{dy}(\mathrm{X} - x) = \frac{du}{dx}(\mathrm{Y} - y),$$

the curve being referred to rectangular axes of co-ordinates.

71. The line TM in fig. 6 is usually called the subtangent and RM the subnormal. It is easily seen that

$$\mathrm{MR} = \frac{ydy}{dx},$$

$$\mathrm{TM} = \frac{y}{\frac{dy}{dx}} = y\frac{dx}{dy},$$

as it may otherwise be written.

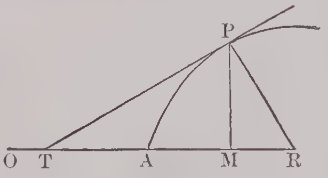

Fig. 6.

Again, if the angle $\mathrm{PTM} = \phi$, we have $\tan\phi = \frac{dy}{dx}$; and the length of the normal

$$\mathrm{PR} = y\sec\phi = y\left(1 + \frac{dy^2}{dx^2}\right)^{\frac{1}{2}};$$

also that of the tangent

$$\mathrm{PT} = y\operatorname{cosec}\phi = y\left(1 + \frac{dx^2}{dy^2}\right)^{\frac{1}{2}}.$$

72. In general, if the equation of a curve be given in terms of any two variable co-ordinates, the position of the tangent at any point can be determined by finding the ultimate ratio of the corresponding elementary variations of the co-ordinates at the point. Newton gave, in his *Opuscula*, several applications of such systems of co-ordinates. In particular, it may be noticed that he considered the case of what are now called *bifocal curves*, *i. e.*, where the equation is expressed in terms of the distances from two fixed points. Newton illustrated his method by finding the tangent to a Cartesian oval, styled by him an *ellipse of the second order*. The same problem, in a more general case, was studied by Leibnitz (*Ac. Erud.*, 1693), who gave a method of drawing tangents to curves given in terms of the distances from any number of fixed points.

73. At a double point on a curve (see CURVE, vol. vi. p. 635), we have $\frac{du}{dx}=0$ and $\frac{du}{dy}=0$; and $\frac{dy}{dx}$ at such a point becomes indeterminate,—being of the form $\frac{0}{0}$,

since
$$\frac{dy}{dx}=-\frac{\frac{du}{dx}}{\frac{du}{dy}}.$$

Applying the method of § 58, the true value of $\frac{\frac{du}{dx}}{\frac{du}{dy}}$ becomes in this case that of

$$\frac{\frac{d^2u}{dx^2}+\frac{d^2u}{dxdy}\frac{dy}{dx}}{\frac{d^2u}{dxdy}+\frac{d^2u}{dy^2}\frac{dy}{dx}};$$

$$i.\,e.,\quad \frac{dy}{dx}=-\frac{\frac{d^2u}{dx^2}+\frac{d^2u}{dxdy}\frac{dy}{dx}}{\frac{d^2u}{dxdy}+\frac{d^2u}{dy^2}\frac{dy}{dx}}.$$

Hence
$$\frac{d^2u}{dx^2}+2\frac{d^2u}{dxdy}\frac{dy}{dx}+\frac{d^2u}{dy^2}\left(\frac{dy}{dx}\right)^2=0.$$

The roots of this equation in $\frac{dy}{dx}$ give the tangents to the two branches of the curve at the double point.

Double points are distinguished into three classes, according as the roots of this equation are (1) real and unequal, (2) real and equal, or (3) imaginary, *i.e.*, as

$$\left(\frac{d^2u}{dxdy}\right)^2-\frac{d^2u}{dx^2}\frac{d^2u}{dy^2}\text{ is }>,\ =,\text{ or }<0.$$

Of these the first are called *nodes*, the second *cusps*, and the third *conjugate points*. They are frequently also styled by Professor Cayley's nomenclature as *crunodes*, *spinodes*, and *acnodes*. See vol. vi. p. 638.

74. In the general discussion of curves it is usually more convenient to refer them to a system of *trilinear co-ordinates* (see vol. vi. p. 635), in which the position of a point is determined by its distances from three fixed lines. The equations of curves in the system are homogeneous.

Again, if (x, y, z), (x', y', z') denote two points in such a system, the co-ordinates of any point on the line joining these points may be represented by

$$\lambda x+\kappa x',\ \lambda y+\kappa y',\ \lambda z+\kappa z'.$$

Hence, to determine the points in which the line joining x, y, z to x', y', z' intersects a curve of the nth degree, we substitute $\lambda x+\kappa x'$, $\lambda y+\kappa y'$, $\lambda z+\kappa z'$ for x, y, z in the equation of the curve, $u=0$; then by Taylor's theorem (§ 57) the result may be written

$$\lambda^n u+\lambda^{n-1}\kappa\left(x'\frac{du}{dx}+y'\frac{du}{dy}+z'\frac{du}{dz}\right)$$
$$+\frac{\lambda^{n-2}\kappa^2}{1\,.\,2}\left(x'\frac{d}{dx}+y'\frac{d}{dy}+z'\frac{d}{dz}\right)^2u+\text{etc.},$$

or
$$\lambda^n u+\lambda^{n-1}\kappa\Delta u+\frac{\lambda^{n-2}\kappa^2}{1\,.\,2}\Delta^2u+\text{etc.},$$

where Δ stands for the symbol of operation

$$\left(x'\frac{d}{dx}+y'\frac{d}{dy}+z'\frac{d}{dz}\right).$$

The roots of this equation in $\frac{\lambda}{\kappa}$ determine the co-ordinates of the points of intersection of the line and the curve.

If the point x, y, z lie on the curve, we have $u=0$; if in addition we have

$$x'\frac{du}{dx}+y'\frac{du}{dy}+z'\frac{du}{dz}=0,\text{ or }\Delta u=0,$$

then a second point of intersection of the line with the curve will be consecutive to x, y, z; and $\Delta u=0$ is the equation to the tangent at the point x, y, z.

Again, if the latter expression Δu vanish identically, the point x, y, z is a double point on the curve; or, in other words, every line passing through it meets two branches of the curve there. The equation $\Delta^2u=0$ is in this case that of the pair of tangent lines at this point to these two branches.

This method is evidently susceptible of much extension.

Asymptotes.

75. The method of the calculus furnishes a ready mode of determining the asymptotes to algebraic curves. By an asymptote we understand a tangent whose point of contact is situated at an infinite distance.

To find the asymptotes to a curve of the nth degree, we suppose its equation written in the form

$$u_n+u_{n-1}+u_{n-2}+\ .\ .\ .\ +u_2+u_1+u_0=0,$$

where u_n is a homogeneous expression of the nth degree in x and y, etc.

Again, writing $u_n=x^nf_0\left(\frac{y}{x}\right)$, $u_{n-1}=x^{n-1}f_1\left(\frac{y}{x}\right)$, etc., the equation becomes

$$x^nf_0\left(\frac{y}{x}\right)+x^{n-1}f_1\left(\frac{y}{x}\right)+x^{n-2}f_2\left(\frac{y}{x}\right)+\text{etc.}=0.$$

Let $y=\kappa x+\nu$ be the equation of any right line; then, to find its points of intersection with the curve we substitute $\kappa+\frac{\nu}{x}$ for $\frac{y}{x}$ in the preceding equation, and after expansion by Taylor's theorem, we arrange according to powers of x; this gives

$$x^nf_0(\kappa)+x^{n-1}\{f_1(\kappa)+\nu f'_0(\kappa)\}$$
$$+x^{n-2}\{f_2(\kappa)+\nu f'_1(\kappa)+\frac{\nu^2}{1\,.\,2}f''_0(\kappa)\}+\text{etc.}=0.$$

Now if the line $y=\kappa x+\nu$ be an asymptote, two of the roots of this equation in x must be infinite, and consequently we have

$$f_0(\kappa)=0,\text{ and }f_1(\kappa)+\nu f'_0(\kappa)=0.$$

If κ' be a root of $f_0(\kappa)=0$, the corresponding value of ν is

$$-\frac{f_1(\kappa')}{f'_0(\kappa')},$$

and the equation
$$y=\kappa'x-\frac{f_1(\kappa')}{f'_0(\kappa')}$$

represents an asymptote.

If $f_1(\kappa')=0$, *i. e.*, if u_{n-1} and u_n have a common factor $y-\kappa'x$, the line $y=\kappa'x$ is an asymptote.

To each root of $f_0(\kappa)=0$ corresponds an asymptote, and accordingly every curve of the nth degree has in general n asymptotes, real or imaginary. If the equation of the curve contains no terms of the degree $n-1$, the n asymptotes are represented by the equation $u_n=0$.

In the case when $f_0(\kappa)$ has a pair of roots each equal to κ', then $f'(\kappa')=0$, and the corresponding value of ν is, in general, infinite. In such cases the corresponding asymptote is situated at infinity. The parabola is the simplest case of this, having the line at infinity for its asymptote. Branches of this class belonging to a curve are called *parabolic*, while a branch having an asymptote within a measurable distance is called *hyperbolic*.

It is easy to establish an analogous method for finding asymptotes to curves whose equations are given in polar co-ordinates.

The equations to the real asymptotes in the following curves are easily found by the above method.

(1) $x^2y^2=a^2(x^2+y^2)+b^4$. *Ans.* $x=\pm a$, $y=\pm a$.

(2) $x^2y^2=a^2(x^2-y^2)+b^3(x+y)$. *Ans.* $y+a=0$, $y-a=0$.

(3) $x^3-x^2y-(a+c)x^2+axy+2a^2y+d=0$.
Ans. $x+a=0$, $x-2a=0$, $x-y-c=0$.

(4) Prove that the asymptotes to a curve of the third degree meet the curve in points which lie on a right line.

(5) Show that the curve $x^3-axy+aby=0$ has a parabolic asymptote, and find its equation.

Curvature, Evolutes, Points of Inflexion.

76. The word curvature indicates deviation from a right line, the curvature at any point on a curve being greater or less according as it deviates more or less rapidly from the tangent at the point.

The curvature at any point on a curve is obtained by determining the circle which has the same curvature as that of the curve at the point. Let ds be an indefinitely small element of the curve, and $d\phi$ the angle between the tangents at its extremities, then $\frac{ds}{d\phi}$ represents the radius of the circle which has the same curvature. $\frac{ds}{d\phi}$ is accordingly called the *radius of curvature* of the curve at the point. The circle is called the *circle of curvature*, and its centre the *centre of curvature*, corresponding to the point on the curve. Denoting the radius of the circle of curvature by ρ, we have

$$\rho=\frac{ds}{d\phi}.$$

Again, if x, y be the co-ordinates of the point, and ϕ be measured from the axis of x, then, since ds is the limit of the hypothenuse of a right-angled triangle of which dx, dy are the limits of the sides, we have

$$\tan\phi = \frac{dy}{dx}; \quad \therefore \frac{d^2y}{dx^2} = \sec^2\phi\,\frac{d\phi}{dx} = \sec^x\phi\,\frac{d\phi}{ds}\cdot\frac{ds}{dx} = \frac{\sec^3\phi}{\rho}.$$

Hence
$$\rho = \frac{\sec^3\phi}{\dfrac{d^2y}{dx^2}} = \frac{\left\{1+\left(\dfrac{dy}{dx}\right)^2\right\}^{\frac{3}{2}}}{\dfrac{d^2y}{dx^2}}.$$

This expression for the radius of curvature was given by John Bernoulli (*Acta Eruditorum*, 1701).

The radius of curvature becomes infinite at a point for which $\frac{d^2y}{dx^2} = 0$. Such points are styled *points of inflexion* on the curve, and the tangent at a point of inflexion is called a *stationary* tangent (vol. vi. p. 635). Other expressions for the radius of curvature can be readily obtained.

For instance, since

$$\cos\phi = \frac{dx}{ds}, \text{ and } \sin\phi = \frac{dy}{ds},$$

if the arc be taken as the independent variable, we have

$$-\sin\phi\,\frac{d\phi}{ds} = \frac{d^2x}{ds^2},\ \cos\phi\,\frac{d\phi}{ds} = \frac{d^2y}{ds^2},$$

$$\therefore \frac{1}{\rho} = \frac{d\phi}{ds} = \sqrt{\left(\frac{d^2x}{ds^2}\right)^2 + \left(\frac{d^2y}{ds^2}\right)^2}.$$

Again, if p be the length of the perpendicular drawn from the origin on the tangent at a point whose distance from the origin is r, the radius of curvature at the point is given by the equation

$$\rho = r\frac{dr}{dp}.$$

This value of ρ can be readily established from geometrical considerations, and is frequently useful, more especially in applications of the calculus to physical astronomy.

77. If the centre of curvature for each point on a plane curve be taken, we get a new curve called its *evolute*. Also, with respect to the evolute, the original curve is called an *involute*, and may be described from its evolute by the unrolling a stretched string supposed wound round the evolute. In this motion each point on the string describes an *involute* to the curve. The curves of the system thus described are said to be *parallel*. Again, from its definition, it is plain that the evolute of a curve is the locus of the points of intersection of the normals drawn at consecutive points on the curve.

78. *Contact of Curves.*—Suppose two curves, represented by the equations $y = f(x)$ and $y = \phi(x)$, to have a point (x, y) in common, then $f(x) = \phi(x)$.

Let $x + h$ be substituted for x in both equations, and suppose y_1 and y_2 to be the corresponding ordinates, then

$$y_1 = f(x+h) = f(x) + hf'(x) + \frac{h^2}{1\,.\,2}f''(x) + \text{etc.},$$

$$y_2 = \phi(x+h) = \phi(x) + h\phi'(x) + \frac{h^2}{1\,.\,2}\phi''(x) + \text{etc.}$$

$$\therefore y_1 - y_2 = h\left\{f'(x) - \phi'(x)\right\} + \frac{h^2}{1\,.\,2}\left\{f''(x) - \phi''(x)\right\} + \text{etc.}$$

Now, if $f'(x) = \phi'(x)$, we have

$$y_1 - y_2 = \frac{h^2}{1\,.\,2}\left\{f''(x) - \phi''(x)\right\} + \frac{h^3}{1\,.\,2\,.\,3}\left\{f'''(x) - \phi'''(x)\right\} + \text{etc.},$$

and the curves have a common tangent. In this case the curves have a contact of the first order, and when h is small, the difference between the ordinates y_1 and y_2 is a small quantity of the second order.

If in addition $f''(x) = \phi''(x)$, we have

$$y_1 - y_2 = \frac{h^3}{1\,.\,2\,.\,3}\left\{f'''(x) - \phi'''(x)\right\} + \text{etc.}$$

In this case the difference of the ordinates is a small quantity of the *third* order; and the curves are said to have a contact of the *second* order, and approach indefinitely nearer to each other at the point of contact than in the former case.

Also, since $y_1 - y_2$ changes its sign with that of h, the curves intersect, as well as touch, at the point of contact.

If, moreover, $f'''(x) = \phi'''(x)$, the curves have a contact of the third order.

In general, if $f(x) = \phi(x)$, $f'(x) = \phi'(x)$, $f''(x) = \phi''(x)$ .... $f^{(n)}(x) = \phi^{(n)}(x)$, the curves are said to have a *contact of the nth order* at the point.

It is plain from what precedes that, if two curves have a contact of the nth order, no curve having with either a contact of a lower order can pass between them.

We shall illustrate this theory of the contact of curves by finding the circle which has a contact of the second order with the curve $y = f(x)$ at the point (x, y).

Suppose $(x - \alpha)^2 + (y - \beta)^2 = \mathrm{R}^2$ to be the equation of the circle, then, by the preceding, $\frac{dy}{dx}$ and $\frac{d^2y}{dx^2}$ must be the same for the circle and for the curve at the point.

Differentiating twice successively the equation of the circle we get

$$x - \alpha + (y - \beta)\frac{dy}{dx} = 0,$$

and
$$1 + \left(\frac{dy}{dx}\right)^2 + (y - \beta)\frac{d^2y}{dx^2} = 0.$$

Hence
$$\mathrm{R}^2 = (x - \alpha)^2 + (y - \beta)^2 = \frac{\left\{1+\left(\dfrac{dy}{dx}\right)^2\right\}^3}{\left(\dfrac{d^2y}{dx^2}\right)^2}.$$

This agrees with the value for the radius of curvature found in § 76, and shows, as is indeed evident, that the circle of curvature is the circle having a contact of the second order at the point in which it touches the curve.

Again, if x, y be eliminated between the preceding differential equations and that of the curve, the resulting equation in α, β is that of the evolute of the curve.

From what has been shown above, if the equation of a curve contain n arbitrary coefficients, we can in general determine their values so that the curve shall have a contact of the order $n - 1$ with a given curve at any point; for the coefficients can be determined so that $y, \frac{dy}{dx}, \frac{d^2y}{dx^2}, \ldots \frac{d^{n-1}y}{dx^{n-1}}$ shall have the same values for the two curves at the point.

The curve thus determined having a contact of the highest order with a given curve at any point is called an *osculating* curve. For instance, as the equation of a right line contains but two independent constants, it admits in general of a contact of the first degree only. Again, the equation of a circle has three independent constants, and accordingly the circle admits in general of a contact of the second degree with a curve at any point. The parabola has four independent constants, and consequently admits of a contact of the third order; and so on.

Again, introducing the additional condition

$$f^{(n)}(x) = \phi^{(n)}(x),$$

a finite number of points is seen to exist at which the osculating curve has a contact one degree higher; thus a tangent may have contact of the second order, an osculating circle contact of the third order, and so on.

In the case of a right line, we have

$$\phi(x) = f(x),\ \phi'(x) = f'(x),\ \phi''(x) = f''(x),$$

where $\phi(x) = ax + b$, $\therefore \phi''(x) = 0$. This agrees with the condition found for a point of inflexion in § 76. The problem of contact admits of being considered also from a geometrical point of view, *i.e.*, from the consideration of the number of *consecutive* points of intersection of two curves.

79. The discussion of evolutes and involutes originated with Huygens, in his celebrated work, *Horologium Oscillatorium* (1673), published before the invention of the calculus. Huygens's investigation is purely geometrical. The definition of the osculating circle was first given by Leibnitz, in the *Acta Eruditorum*, 1686, where he pointed out its great importance in the study of curves. Newton, in his *Principia*, makes frequent use of the theory of the radius of curvature, and of its connection with evolutes.

Newton also observed that the radius of curvature becomes infinite at a point of inflexion, and vanishes at a cusp—called by him *punctum rectitudinis*, and *punctum curvaturæ infinitæ*, respectively. See *Opusc.*, i. pp. 121, 122, ed. Cast.

It is worthy of remark that Sluze, in his *Mesolabum seu duæ mediæ proportionales*, etc. (1659), pointed out a general method for the determination of points of inflexion (*puncta flexus contrarii*), by reducing it to a question of *maxima* and *minima*, viz., to finding when the intercept made by the tangent, measured along any axis from a fixed point on it, is a maximum or a minimum. This method he applied successfully to the conchoid of Nicomedes.

(1) It is easily found as above that the radius of curvature at any point on the curve $3a^2y = x^4$ is equal to

$$\rho = \frac{(a^4 + x^4)^{\frac{3}{2}}}{2a^4x}.$$

(2) The following expression for the radius of curvature in polar co-ordinates,—

$$\rho = \frac{\left\{ r^2 + \left(\frac{dr}{d\theta}\right)^2 \right\}^{\frac{3}{2}}}{r^2 - r\frac{d^2r}{d\theta^2} + 2\left(\frac{dr}{d\theta}\right)^2},$$

can be easily deduced.

(3) If $u = \frac{1}{r}$, this becomes

$$\rho = \frac{\left\{ 1 + \left(\frac{du}{ud\theta}\right)^2 \right\}^{\frac{3}{2}}}{u + \frac{d^2u}{d\theta^2}}.$$

(4) Hence at a point of inflexion we have

$$u + \frac{d^2u}{d\theta^2} = 0.$$

(5) The origin is a point of inflexion on the curve represented by the equation $u_3 + u_1 = 0$.

(6) The length of the radius of curvature at the origin in the curve $r = a \sin n\theta$ is $\frac{1}{2}na$.

(7) If on the tangent to a curve a constant length be measured from the point of contact, the normal to the locus of the points thus taken passes through the corresponding centre of curvature of the proposed curve.

(8) In the ellipse $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, if we take $x = a\cos\phi$, $y = b \sin\phi$, the co-ordinates α, β of the centre of curvature of any point are given by the equations

$$\alpha = \frac{a^2 - b^2}{a}\cos^3\phi;\ \beta = \frac{b^2 - a^2}{b}\sin^3\phi.$$

(9) At a cusp (compare § 73) the radius of curvature is zero for both branches.

(10) In some cases two branches of the same curve may have a contact of the second or of a higher order. For instance, it is easy to show that at the origin two branches of the curve

$$y^2 - 2x^3y + x^4 - x^5 = 0$$

have equal finite radii of curvature.

Envelopes.

80. If we suppose a series of different values given to α in the equation

$$f(x, y, \alpha) = 0,$$

then for each value we get a distinct curve, and the above equation may be regarded as representing an indefinite number of curves, a single determinate curve corresponding to each distinct value of α, provided α enters into the equation in a rational form only.

If now we regard the *parameter* α as varying continuously, and consider the two curves

$$f(x, y, \alpha) = 0, \quad f(x, y, \alpha + \Delta\alpha) = 0,$$

then the co-ordinates of their points of intersection satisfy each of these equations, and therefore also satisfy the equation

$$\frac{f(x, y, \alpha + \Delta\alpha) - f(x, y, \alpha)}{\Delta\alpha} = 0.$$

Now, in the limit, when $\Delta\alpha$ is infinitely small, the latter equation becomes

$$\frac{df(x, y, \alpha)}{d\alpha} = 0.$$

Hence the locus of the points of *ultimate* intersection for the entire system of curves represented by $f(x, y, \alpha) = 0$ is obtained by eliminating α between the equations

$$f(x, y, \alpha) = 0 \text{ and } \frac{df(x, y, \alpha)}{d\alpha} = 0.$$

This locus is called the *envelope* of the system, and it can be easily seen that it is touched by every curve of the system.

For instance, suppose L, M, N to be given functions of x and y, and α a parameter, to find the envelope of the system of curves represented by the equation

$$L\alpha^2 + 2M\alpha + N = 0.$$

Here $\quad f(x, y, \alpha) = L\alpha^2 + 2M\alpha + N;$

$$\therefore \frac{df(x, y, \alpha)}{d\alpha} = 2L\alpha + 2M.$$

Consequently the envelope is the curve represented by the equation

$$LN = M^2.$$

For example, if L, M, N represent right lines, the envelope of the moving line

$$L\alpha^2 + 2M\alpha + N = 0,$$

is the conic $LN = M^2$.

In general, if the equation of the moving curve be of the form

$$P_0\alpha^n + P_1\alpha^{n-1} + P_2\alpha^{n-2} + \ldots + P_n = 0,$$

where $P_0, P_1, P_2 \ldots P_n$ are given functions of x and y, the envelope is obtained by the elimination of α between the proposed equation and its derived equation

$$nP_0\alpha^{n-1} + (n-1)P_1\alpha^{n-2} + \text{etc.} = 0.$$

It is accordingly represented by the condition that the equation in α should have equal roots; this condition is called the *discriminant* of the equation. For examples see Salmon's *Higher Plane Curves*, Arts. 85, 86.

81. In many cases the equation of the moving curve is of the form

$$f(x, y, \alpha, \beta) = 0,$$

where the parameters α, β are connected by an equation

$$\phi(\alpha, \beta) = 0.$$

In this case we regard β as a function of α, and thus we get by differentiation

$$\frac{df}{d\alpha} + \frac{df}{d\beta}\frac{d\beta}{d\alpha} = 0, \qquad \frac{d\phi}{d\alpha} + \frac{d\phi}{d\beta}\frac{d\beta}{d\alpha} = 0;$$

consequently, if we make

$$\frac{df}{d\alpha} = \lambda\frac{d\phi}{d\alpha}, \text{ we get } \frac{df}{d\beta} = \lambda\frac{d\phi}{d\beta},$$

and the required envelope is obtained by the elimination of α, β, λ between these and the two given equations.

For example, let it be proposed to find the envelope of a line of given length (a), whose extremities move along two fixed rectangular axes.

Here, taking the fixed lines for co-ordinate axes, and denoting the intercepts by α and β, we have

$$\frac{x}{\alpha} + \frac{y}{\beta} = 1, \text{ and } \alpha^2 + \beta^2 = a^2.$$

Hence $\quad \frac{x}{\alpha^2} = \lambda\alpha, \quad \frac{y}{\beta^2} = \lambda\beta;$

from which we get

$$\lambda = \frac{1}{a^2}, \quad \therefore \alpha^3 = a^2x, \quad \beta^3 = a^2y,$$

and the equation of the envelope is

$$x^{\frac{2}{3}} + y^{\frac{2}{3}} = a^{\frac{2}{3}}.$$

This envelope was discussed by John Bernoulli in the *Acta Erud.*, 1692.

Again, to find the equation to the evolute of an ellipse, regarded as the envelope of its normals. Here we have the equations

$$a^2\frac{x}{\alpha} - b^2\frac{y}{\beta} = a^2 - b^2, \text{ and } \frac{\alpha^2}{a^2} + \frac{\beta^2}{b^2} = 1,$$

where α, β are the co-ordinates of a point on the ellipse.

Hence $\quad \frac{a^2x}{\alpha^2} = \lambda\frac{\alpha}{a^2}, \qquad \frac{b^2y}{\beta^2} = -\lambda\frac{\beta}{b^2},$

and we easily obtain as the required equation

$$(ax)^{\frac{2}{3}} + (by)^{\frac{2}{3}} = (a^2 - b^2)^{\frac{2}{3}}.$$

The preceding method can be readily extended to the general case in which the equation of the moving curve contains any number n of variable parameters, which are connected by $n-1$ equations of condition.

82. The theory of envelopes, or of ultimate intersections, may be said to have originated with the investigations of Huygens on evolutes, already referred to, and those of Tschirnhausen on caustics (*Acta Eruditorum*, 1682). These authors, however, merely treated geometrically a few cases of moving right lines, and did not give any general method for the investigation of such problems. Leibnitz was the first who gave a general process for the solution of this class of questions (*Acta Eruditorum*, 1692, 1694). His method does not differ in any material respect from that here given.

(1) To find the envelope of the parabolas described by a projectile discharged from a given point with a given velocity, but at different angles of elevation.

If e be the angle of elevation, and h the height due to the initial velocity, the equation of the parabolic path is

$$x = y\tan e - \frac{y^2}{4h\cos^2 e}.$$

Let $\tan e = \alpha$, and the equation becomes

$$x = \alpha y - \frac{y^2}{4h}(1 + \alpha^2), \text{ or } \frac{y^2}{4h} + x - \alpha y + \alpha^2\frac{y^2}{4h} = 0.$$

Consequently the equation to the required envelope is

$$y^2 = 4h(h - x),$$

which represents a parabola.

This problem is the first that was brought forward on the locus of the ultimate intersection of *curved lines.* It was proposed by Duillier to John Bernoulli, who solved it, but not by any general method (*Commer. Epist. Leib. et Bern.*, vol. i. p. 17).

(2) To find the envelope of the system of conics represented by the equation

$$\frac{x^2}{\alpha}+\frac{y^2}{\alpha-n}=1\,,$$

where α is a variable parameter. Proceeding as before we get as the equation to the envelope $(x\pm\sqrt{n})^2+y^2=0$. Hence we infer that a system of confocal conics may be regarded as inscribed in the same imaginary quadrilateral.

(3) Find the envelope of the plane

$$\frac{x}{l}+\frac{y}{m}+\frac{z}{n}=1$$

in which the parameters l, m, n are connected by the equation $lmn=a^3$. *Ans.* $27\,xyz=a^3$.

(4) A right line revolves with a uniform angular velocity, while one of its points moves uniformly along a fixed right line, prove that its envelope is a cycloid.

Symbolic Methods.

83. The analogy between successive differentiation and ordinary exponentials was perceived by Leibnitz and the early writers on the calculus, and afterwards more especially by Lagrange (*Mém. Acad. Berlin*, 1772). Arbogast was, however, the first to separate the symbol of operation from that of quantity in a differential equation (*Calcul des Dérivations*, 1800.) The first writers who appear to have given correct rules on the subject of operations were François, *Ann. des Math.*, 1812, and Servois, in the same journal, in 1814. Servois more especially exhibited the principles on which the legitimacy of the separation of the symbols of operation from those of quantity depends; and, making a separate calculus of functions out of those properties, he succeeded in proving that differences, differentiations, and multiplications by any factors which are independent of the variable, may be employed as if the symbols of operation were ordinary algebraic quantities. Hence has arisen a new method of considering the principles and processes of the calculus, called the symbolic method, or the calculus of operations.

In this method $\frac{du}{dx}$ is written in the form $\left(\frac{d}{dx}\right)u$, and the symbol $\frac{d}{dx}$ is regarded in the light of an operation, supposed to be made on the function u according to the established principles of differentiation.

Again $$\frac{d}{dx}\,(u+v)=\left(\frac{d}{dx}\right)u+\left(\frac{d}{dx}\right)v \quad . \quad . \quad . \quad (1).$$

Also, $$\left(\frac{d}{dx}\right)^m\left(\frac{d}{dx}\right)^n u=\left(\frac{d}{dx}\right)^{m+n}u \quad . \quad . \quad . \quad (2).$$

And, if u be a function of x and y,

$$\left(\frac{d}{dx}\right)\left(\frac{d}{dy}\right)u=\left(\frac{d}{dy}\right)\left(\frac{d}{dx}\right)u \quad . \quad . \quad . \quad (3).$$

Hence we observe that the symbols $\frac{d}{dx}$ and $\frac{d}{dy}$ operate and are combined according to the same laws as ordinary algebraic symbols of quantity, such as a and b; and we can readily infer that the theorems in ordinary algebra (compare ALGEBRA, vol. i. p. 458, § 8, 9) which depend solely on such laws of combination are capable of being extended to similar theorems depending on the symbols $\frac{d}{dx}$ and $\frac{d}{dy}$, or on the symbol $\frac{d}{dx}$ and any constant a. Such results are in general capable of extension to any symbols that are subject to the same laws of combination.

The law embodied in equation (1) is called the *distributive* law; the second, in (2), is called the *index* or *exponential* law; and the third, in (3), the *commutative* law.

It is convenient to denote the preceding symbols by single letters. Accordingly we may suppose the symbol $\frac{d}{dx}$ to be represented by D, and $\frac{d}{dy}$ by D′, etc.

In general, if π, ρ denote two symbols of operation such that

$$\pi(u+v)=\pi u+\pi v\,,$$
$$\rho(u+v)=\rho u+\rho v\,,$$
$$\pi\rho u=\rho\pi u\,,$$
$$\pi^m\pi^n u=\pi^{m+n}u\,,$$

then the symbols π, ρ possess the distributive, commutative, and exponential properties.

For example, suppose E_h represent the operation of changing x into $x+h$ in any function of x, *i.e.*, suppose

$$\mathrm{E}_h\phi(x)=\phi(x+h).$$

Then

$$\mathrm{E}_h\,|\,\phi(x)+\psi(x)\,|=\phi(x+h)+\psi(x+h)=\mathrm{E}_h\phi(x)+\mathrm{E}_h\psi(x)\,.$$

Moreover, E_k denoting the operation of changing x into $x+k$, we have

$$\mathrm{E}_k\phi(x)=\phi(x+k),\ \therefore\ \mathrm{E}_h\,.\,\mathrm{E}_k\phi(x)=\mathrm{E}_h\phi(x+k)=\phi(x+h+k)\,.$$

In like manner

$$\mathrm{E}_k\mathrm{E}_h\phi(x)=\phi(x+h+k)=\mathrm{E}_{h+k}\phi(x),\ \therefore\ \mathrm{E}_h\mathrm{E}_k\phi(x)=\mathrm{E}_k\mathrm{E}_h\phi(x)\,.$$

Hence, the symbols E_h, E_k are commutative.

Also the equation

$$\mathrm{E}_k\mathrm{E}_h\phi(x)=\mathrm{E}_{h+k}\phi(x)$$

may be written, symbolically, thus:—

$$\mathrm{E}_k\mathrm{E}_h=\mathrm{E}_{h+k}.$$

This shows that the symbol E_h is of the nature of an exponential; and may be written in the form E^h.

84. This symbol can also be connected with Taylor's expansion. Thus, if we separate the symbols of operation from those of quantity in Taylor's theorem, it may be written

$$f(x+h)=\left(1+h\mathrm{D}+\frac{h^2}{1\,.\,2}\mathrm{D}^2+\frac{h^3}{1\,.\,2\,.\,3}\mathrm{D}^3+\ .\ .\ .\right)$$
$$f(x)=e^{h\mathrm{D}}f(x).$$

Accordingly, although we can give no direct meaning to the symbol $e^{h\mathrm{D}}$, except as the representative of the symbolic expansion

$$1+h\mathrm{D}+\frac{h^2}{1\,.\,2}\mathrm{D}^2+\ .\ .\ .\ +\frac{h^n}{\lfloor n}\mathrm{D}^n\ .\ .\ .$$

we may from the preceding section regard it as equivalent to the symbol E^h.

In like manner we may write

$$e^{h\mathrm{D}}\,\phi(x,\,y)=\phi(x+h,\,y)\,.$$

If now we suppose both sides operated on by the symbol $e^{k\mathrm{D}'}$, we have

$$e^{k\mathrm{D}'}\,.\,e^{h\mathrm{D}}\,.\,\phi(x,\,y)=e^{k\mathrm{D}'}\phi(x+h,\,y)=\phi(x+h,\,y+k)\,.$$

Hence

$$\phi(x+h,\,y+k)=e^{h\mathrm{D}+k\mathrm{D}'}\phi(x,\,y)$$
$$=\left\{1+(h\mathrm{D}+k\mathrm{D}')+\tfrac{1}{2}(h\mathrm{D}+k\mathrm{D}')^2+\ .\ .\ .\ \right\}\phi(x,\,y)=\phi(x,\,y)$$
$$+h\frac{d\phi}{dx}+k\frac{d\phi}{dy}+\tfrac{1}{2}\left(h^2\frac{d^2\phi}{dx^2}+2hk\frac{d^2\phi}{dxdy}+k^2\frac{d^2\phi}{dy^2}\right)+\text{etc.},$$

(Compare § 57; also Arbogast, *Cal. des Dér.*, pp. 343–352.)

85. Another proof, by the method of operations, of the foregoing symbolic expression for Taylor's theorem may be added.

It has already been shown that *when* h *is infinitely small* we may write

$$\phi(x+h)-\phi(x)=h\phi'(x)=h\mathrm{D}\phi(x),\ \therefore\ \phi(x+h)=(1+h\mathrm{D})\phi(x)\,.$$

In like manner

$$(1+h\mathrm{D})^2\phi(x)=(1+h\mathrm{D})\,\phi(x+h)=\phi(x+2h),\ \text{etc.}$$

And in general

$$\phi(x+nh)=(1+h\mathrm{D})^n\phi(x)\,.$$

Now suppose $nh=\alpha$, and we get

$$\phi(x+\alpha)=(1+h\mathrm{D})^{\frac{\alpha}{h}}\phi(x)\,.$$

But when h is infinitely small, we may, by analogy (see § 21), assume

$$(1+h\mathrm{D})^{\frac{1}{h}}u=e^{\mathrm{D}}u,\ \therefore\ (1+h\mathrm{D})^{\frac{\alpha}{h}}u=e^{\alpha\mathrm{D}}u.$$

Hence $$\phi(x+\alpha)=e^{\alpha\mathrm{D}}\phi(x),\ \text{as before.}$$

86. Again, as in § 84, representing the symbol e^{D} by E, we may write

$$e^{\mathrm{D}}f(x)=\mathrm{E}f(x).$$

Also, if Δ prefixed to any function of x denote the operation of taking the increment of that function when x receives the increment unity, we have

$$f(x+1)-f(x)=\Delta f(x).$$

Accordingly $$\mathrm{E}f(x)=(1+\Delta)\,f(x).$$

And, by the index law, we have

$$\mathrm{E}^nf(x)=(1+\Delta)^nf(x),$$

or $$f(x+n)=\left(1+n\Delta+\frac{n\,.\,(n-1)}{1\,.\,2}\Delta^2+\ .\ .\ .\right)f(x)$$
$$=f(x)+n\Delta f(x)+\frac{n\,.\,(n-1)}{1\,.\,2}\Delta^2f(x)+\text{etc.}$$

Adopting the notation $\phi(x)=u_x$, $\phi(x+h)=u_{x+h}$, etc., this leads to the following fundamental theorem of the calculus of finite differences

$$u_{x+n}=u_x+n\Delta u_x+\frac{n(n-1)}{1\,.\,2}\Delta^2 u_x+\ldots$$

Again since

$$\Delta=\mathrm{E}-1, \text{ we have } \Delta^n u_x=(\mathrm{E}-1)^n u_x.$$

Hence, in like manner,

$$\Delta^n u_x=u_{x+n}-nu_{x+n-1}+\frac{n(n-1)}{1\,.\,2}u_{x+n-2}+\ldots+(-1)^n u_x.$$

For example,

$$\Delta^n x^m=(x+n)^m-n(x+n-1)^m+\ldots+(-1)^n x^m.$$

Again, if $\Delta^n 0^m$ represent the value of $\Delta^n x^m$ when $x=0$, we have

$$\Delta^n 0^m=n^m-n(n-1)^m+\frac{n(n-1)}{1\,.\,2}(n-2)^m-\ldots+(-1)^{n-1}n.$$

The numbers represented by the symbol $\Delta^n 0^m$, called the differences of the powers of zero, are of frequent occurrence in analysis, and their values can be readily tabulated from this series.

87. Again, since

$$\mathrm{D}(uv)=\frac{d}{dx}(uv)=v\frac{d}{dx}u+u\frac{d}{dx}v=(\mathrm{D}_1+\mathrm{D}_2)uv,$$

in which we suppose D_1 to operate on u only, and D_2 on v only, we infer that

$$\begin{aligned}\mathrm{D}^n(uv)&=(\mathrm{D}_1+\mathrm{D}_2)^n uv\\&=\left\{\mathrm{D}_1{}^n+n\mathrm{D}_1{}^{n-1}\mathrm{D}_2+\frac{n(n-1)}{1\,.\,2}\mathrm{D}_1{}^{n-2}\mathrm{D}_2^2+\ldots\right\}uv\\&=v\frac{d^n u}{dx^n}+n\frac{dv}{dx}\frac{d^{n-1}u}{dx^{n-1}}+\frac{n(n-1)}{1\,.\,2}\frac{d^2v}{dx^2}\frac{d^{n-2}u}{dx^{n-2}}+\ldots+u\frac{d^n v}{dx^n}.\end{aligned}$$

This is Leibnitz's theorem, given in § 27.

This result can be extended to the nth differential of the product of any number of functions.

88. More generally, if $\psi(x)$ represent any function of x, and if $f(x)$ be any rational function, and we suppose D_1 operates on u only, and D_2 on $\psi(x)$ only, we have

$$\begin{aligned}f(\mathrm{D})\psi(x)u&=f(\mathrm{D}_1+\mathrm{D}_2)\psi(x)u\\&=\left\{f(\mathrm{D}_1)+\mathrm{D}_2f'(\mathrm{D}_1)+\ \ldots\right\}\psi(x)u\\&=\psi(x)f(\mathrm{D})u+\psi'(x)f'(\mathrm{D})u+\frac{\psi''(x)}{1\,.\,2}f''(\mathrm{D})u+\text{etc.}\end{aligned}$$

In like manner the equation

$$f(x)\psi(\mathrm{D})u=\psi(\mathrm{D})f(x)u-\psi'(\mathrm{D})f'(x)u+\frac{\psi''(\mathrm{D})}{1\,.\,2}f''(x)u-\ldots$$

can be established.

These expansions form the basis of Hargreave's well-known memoir on the "Solution of Differential Equations" (*Philosophical Transactions*, 1848). Hargreave observes that on mere inspection of these results it is apparent that if D be substituted for x, and $-x$ for D, the former equation transforms into the latter. Hence, in any differential equation and in its symbolical solution, if the foregoing substitutions be made we shall obtain another form, accompanied with its symbolical solution. This principle was applied by Hargreave to the solution of several classes of differential equations.

89. Again, if in Leibnitz's theorem we make $v=e^{ax}$, we get

$$\begin{aligned}\mathrm{D}^n(e^{ax}u)&=e^{ax}\left(\mathrm{D}^n u+na\mathrm{D}^{n-1}u+\frac{n\,.\,n-1}{1\,.\,2}a^2\mathrm{D}^{n-2}u+\ldots\right)\\&=e^{ax}\left(\mathrm{D}^n+na\mathrm{D}^{n-1}+\frac{n\,.\,n-1}{1\,.\,2}a^2\mathrm{D}^{n-2}+\ \ldots\ \right)u\\&=e^{ax}(\mathrm{D}+a)^n u.\end{aligned}$$

Accordingly

$$(\mathrm{D}+a)^n u=e^{-ax}\mathrm{D}^n(e^{ax}u).$$

Hence we readily infer that, if $f(a)$ represent any function involving only *positive integral* powers of a, we shall have

$$f(\mathrm{D}+a)u=e^{-ax}f(\mathrm{D})e^{ax}u.$$

Again, if this be transformed by assuming $e^x=y$, we have $\frac{dy}{dx}=y$, and

$$\therefore\ \left(\frac{d}{dx}\right)u=\frac{dy}{dx}\left(\frac{d}{dy}\right)u=\left(y\frac{d}{dy}\right)u=y\mathrm{D}'u.$$

Hence the foregoing result may be exhibited as follows:—

$$f(y\mathrm{D}'+a)u=y^{-a}f(y\mathrm{D}')y^a u.$$

This may be written

$$f(x\mathrm{D}+a)u=x^{-a}f(x\mathrm{D})x^a u.$$

90. The interpretation of negative and fractional powers of a symbol of operation is a subject necessarily suggested by the introduction of such symbols. We pass over all allusion to the case of fractional powers, as no satisfactory theory for their interpretation has as yet been arrived at. The interpretation of an integer negative power of a symbol is easily established, and is in all cases of the nature of an inverse problem.

For instance let π be a symbol of operation such that

$$\pi u=v,$$

then, if v be given and u unknown, we may write

$$u=\pi^{-1}v,$$

and the problem contained in the inverse symbol of operation will be answered, when, by any process, we have determined u so as to satisfy the equation $\pi u=v$, or $\pi\pi^{-1}v=v$. In other words, we define the inverse symbol π^{-1} to be that which the direct operation π simply annuls; and this is in accordance with the analogy of ordinary algebra.

For example, since $\mathrm{D}f(x)=f'(x)$, we write $\mathrm{D}^{-1}f'(x)=f(x)$, and the symbol D^{-1} is equivalent to an integration. In like manner D^{-n} is equivalent to n successive integrations.

Similarly the symbol $(\mathrm{D}+a)^{-n}$ is regarded as the inverse of the symbol $(\mathrm{D}+a)^n$, *i.e.*, such that

$$(\mathrm{D}+a)^n(\mathrm{D}+a)^{-n}u=u.$$

We now proceed to investigate how far the equation

$$f(\mathrm{D}+a)u=e^{-ax}f(\mathrm{D})e^{ax}u$$

holds for inverse symbols.

We have already seen that when n is a positive integer

$$(\mathrm{D}+a)^n u=e^{-ax}\mathrm{D}^n e^{ax}u=v, \text{ suppose; } \therefore\ u=(\mathrm{D}+a)^{-n}v.$$

Moreover from the equation

$$e^{-ax}\mathrm{D}^n e^{ax}u=v$$

we get $\quad \mathrm{D}^n e^{ax}u=e^{ax}v,$

or $\quad u=e^{-ax}\mathrm{D}^{-n}e^{ax}v.$

Consequently $\quad (\mathrm{D}+a)^{-n}v=e^{-ax}\mathrm{D}^{-n}e^{ax}v.$

Hence we infer that the symbolic equation also holds for negative powers of D.

91. In general, since

$$\mathrm{D}.e^{\phi(x)}u=e^{\phi(x)}\{\mathrm{D}+\phi'(x)\}u,$$

we have $\quad \{\mathrm{D}+\phi'(x)\}u=e^{-\phi(x)}\mathrm{D}e^{\phi(x)}u.$

Again

$$\begin{aligned}\{\mathrm{D}+\phi'(x)\}^2u&=e^{-\phi(x)}\mathrm{D}e^{\phi(x)}e^{-\phi(x)}\mathrm{D}e^{\phi(x)}u,\\&=e^{-\phi(x)}\mathrm{D}^2e^{\phi(x)}u;\end{aligned}$$

and in general

$$\{\mathrm{D}+\phi'(x)\}^n u=e^{-\phi(x)}\mathrm{D}^n e^{\phi(x)}u,$$

where n is an integer.

From this we conclude that in all interpretable cases we have

$$f\{\mathrm{D}+\phi'(x)\}u=e^{-\phi(x)}f(\mathrm{D})e^{\phi(x)}u.$$

The results here given have been generalized and extensively employed in the integration of differential equations by Boole. See *Philosophical Transactions*, 1844; also Boole's *Differential Equations*, chapter xvii.

92. We conclude this short account of symbolic methods by applying them to establish one or two well-known formulæ.

It has been shown already (§ 84) that we may write

$$(e^{h\mathrm{D}}-1)\phi(x)=\phi(x+h)-\phi(x).$$

Hence $\quad \phi(x)=(e^{h\mathrm{D}}-1)^{-1}\{\phi(x+h)-\phi(x)\}.$

Multiplying by h, and operating on both sides with the symbol of differentiation D, we get

$$h\phi'(x)=\left(\frac{h\mathrm{D}}{e^{h\mathrm{D}}-1}\right)\left\{\phi(x+h)-\phi(x)\right\}.$$

But, by analogy from § 53, we may write

$$\begin{aligned}&\left(\frac{h\mathrm{D}}{e^{h\mathrm{D}}-1}\right)\Big(\phi(x+h)-\phi(x)\Big)\\&=\left(1-\frac{h\mathrm{D}}{2}+\frac{\mathrm{B}_1h^2\mathrm{D}^2}{1.2}-\frac{\mathrm{B}_2h^4\mathrm{D}^4}{1.2.3.4}+\ \ldots\ \right)\Big(\phi(x+h)-\phi(x)\Big)\\&=\phi(x+h)-\phi(x)-\frac{h}{2}\left\{\phi'(x+h)-\phi'(x)\right\}\\&\quad+\frac{\mathrm{B}_1h^2}{1\,.\,2}\left\{\phi''(x+h)-\phi''(x)\right\}\\&\quad-\frac{\mathrm{B}_2h^4}{1.2.3.4}\left\{\phi^{\text{iv}}(x+h)-\phi^{\text{iv}}(x)\right\}+\text{etc.}\end{aligned}$$

Hence

$$\phi(x+h)=\phi(x)+\frac{h}{2}\left\{\phi'(x+h)+\phi'(x)\right\}$$
$$-\frac{h^2}{12}\left\{\phi''(x+h)-\phi''(x)\right\}$$
$$+\frac{h^4}{720}\left\{\phi^{\text{iv}}(x+h)-\phi^{\text{iv}}(x)\right\}-\ldots.$$
$$+(-1)^n\frac{B_nh^{2n}}{1.2\ldots 2n}\left\{\phi^{2n}(x+h)-\phi^{2n}(x)\right\}+\text{etc.}$$

This result is due to Stirling, and has important applications.

To complete this proof it is necessary to consider the question of the convergency or divergency of this series. On this investigation see Bertrand, *Calcul Intégral*, Art. 374.

93. Again, in the calculus of finite differences, if we consider the finite symbol of summation Σ as the inverse to that of finite differences Δ, we have

$$\Sigma\phi(x)=\Delta^{-1}\phi(x)=\frac{1}{e^{D}-1}\phi(x)$$
$$=\left(D^{-1}-\tfrac{1}{2}+\frac{B_1D}{1.2}-\frac{B_2D^3}{1.2.3.4}+\ldots\right)\phi(x)$$
$$=\int\phi(x)dx-\tfrac{1}{2}\phi(x)+\frac{B_1}{1.2}\phi'(x)-\frac{B_2}{1.2.3.4}\phi'''(x)+\text{etc.}$$
$$=C+\int\phi(x)dx-\frac{\phi(x)}{2}+\frac{1}{12}\phi'(x)-\frac{1}{720}\phi'''(x)+\frac{1}{30240}\phi^{\text{v}}(x)\ldots$$

This theorem is due to Euler; the foregoing demonstration was given by Gregory (*Camb. Math. Journal*, 1837).

On the limits of the remainder after n terms in this series, see Boole's *Finite Differences*, pp. 91–93; also Mr. J. W. L. Glaisher, in *Quarterly Journal of Mathematics*, 1872.

In concluding this brief account of symbolic methods we may observe that the general principles of the theory of operations have been studied in a comprehensive manner by Grassmann, and by Hankel, who applied them to the general theory of complex variables and of quaternions. See Grassmann's *Ausdehnungslehre* (1862), and Hankel's *Vorlesungen über die Complexen Zahlen*, 1867. The reader will find Grassmann's method fully discussed in Hoüel's *Calcul Infinitésimal*, vol. i.

We add a few miscellaneous examples of these methods.

(1) Prove the symbolic equation

$$x^nD^nu=xD(xD-1)(xD-2)\ \ldots\ (xD-n+1)u.$$

(2) Prove that

$$D^r(e^{ax}x^n)=\left(\frac{x}{a}\right)^{n-r}D^n(e^{ax}x^r).$$

(3) Prove the symbolic equation in finite differences

$$(E-a)^nX=a^{n+x}\Delta^na^{-n}X,$$

where E is the symbol e^D (Gregory, *Camb. Math. Jour.*, 1837).

(4) If π and ρ be symbols of operation such that

$$\pi\rho-\rho\pi=\rho_1,\quad \pi\rho_1-\rho_1\pi=\rho_2,\quad \pi\rho_2-\rho_2\pi=\rho_3\ \ldots$$

prove the following symbolic equation

$$f(\pi)\rho=\rho f(\pi)+\rho_1f'(\pi)+\frac{\rho_2}{1.2}f''(\pi)+\ \ldots$$

See Donkin, *Camb. and Dub. Math. Jour.*, 1850.

(5) From the preceding the following symbolic equations can be readily deduced.

$$f\left(D+\frac{X'}{X}\right)=f(D)+\frac{X'}{X}f'(D)+\frac{1}{1.2}\frac{X''}{X}f''(D)+\ldots$$
$$f\left(x+\frac{\phi'(D)}{\phi(D)}\right)=f(x)+f'(x)\frac{\phi'(D)}{\phi(D)}+\frac{f''(x)}{1.2}\frac{\phi''(D)}{\phi(D)}+\ \ldots$$

(Donkin, *ibid.*)

(6) Every differential equation of the form

$$\left\{(a+bx+cx^2+\ldots)D^n+(a'+b'x+\ldots)D^{n-1}+\ldots\right\}u=X$$

can be transformed into the shape

$$\left\{f_0(xD)+f_1(xD)x+f_2(xD)x^2+\ \ldots\right\}u=X.\quad\text{(Boole.)}$$

(7) Apply the method of operation to the proof of Herschel's expansion for $F(e^t)$ (*Philosophical Transactions*, 1816).

If we make $\theta=0$ in the equation

$$f(D)\,e^{t\theta}=e^{t\theta}f(t),$$

we have

$$f(t)=f(D)e^{0t},\text{ where D represents the symbol }\frac{d}{d0}.$$

If now $f(t)=F(e^t)$, we get

$$F(e^t)=F(e^D)\,.\,e^{0t}=F(1+\Delta)e^{0t}$$
$$=F(1+\Delta)\left\{1+0t+\frac{0^2.t^2}{1.2}+\ \ldots\ \right\}$$
$$=F(1)+tF(1+\Delta).0+\frac{t^2}{1.2}F(1+\Delta).0^2+\text{etc.}$$

(Gregory, *Camb. Math. Jour.*, 1838.)

(8) Prove the equation.

$$f(D)\phi(e^x)e^{rx}=\phi(E)f(r)e^{rx},$$

where D represents $\frac{d}{dx}$, and E represents $e^{\frac{d}{dr}}$.

Also $$f\left(\frac{d}{dx}+r\right)\phi(x)=\phi\left(\frac{d}{dr}+x\right)f(r).$$

(Bronwin, *Camb. and Dub. Math. Jour.*, 1848.)

(9) Prove the symbolic equation

$$\phi\left(\frac{d}{dD}\right)f(D)X=f(D)\phi(x-\dot{x})X,$$

where $\dot{x}$ is to be regarded as a variable independent of the operation D, but which, after the operations, is to be replaced by x. (Crofton, *Quar. Math. Jour.*, 1879; also Donkin, *Camb. and Dub. Math. Jour.*, 1850.)

Change of Independent Variable.

94. In the application of the calculus it is often necessary to adopt in our equations new independent variables instead of those originally selected.

Thus, suppose it be required to transform a function of $y, x, \frac{dy}{dx}, \frac{d^2y}{dx^2}$, etc., into a function of $y, t, \frac{dy}{dt}, \frac{d^2y}{dt^2}$, x being supposed a function of t.

Let the functions $\frac{dx}{dt}, \frac{d^2x}{dt^2}$, etc., be represented by x', x'', etc., then we have in all cases

$$\frac{du}{dx}=\frac{1}{x'}\frac{du}{dt},\quad \therefore\ \frac{dy}{dx}=\frac{1}{x'}\frac{dy}{dt};$$

also $$\frac{d^2y}{dx^2}=\frac{d}{dx}\left(\frac{1}{x'}\frac{dy}{dt}\right)=\frac{1}{x'}\frac{d}{dt}\left(\frac{1}{x'}\frac{dy}{dt}\right)=\frac{1}{x'^3}$$
$$x'\frac{d^2y}{dt^2}-x''\frac{dy}{dt}.$$

Again $$\frac{d^3y}{dx^3}=\frac{d}{dx}\left(\frac{x'\frac{d^2y}{dt^2}-x''\frac{dy}{dt}}{x'^3}\right)=\frac{1}{x'}\frac{d}{dt}\left(\frac{x'\frac{d^2y}{dt^2}-x''\frac{dy}{dt}}{x'^3}\right)$$
$$=\frac{1}{x'^5}\left\{x'^2\frac{d^3y}{dt^3}-3x'x''\frac{d^2y}{dt^2}+\frac{dy}{dt}\left(3(x'')^2-x'x''x'''\right)\right\};$$

and so on for differentials of higher order.

If y be taken as the independent variable, we have

$$\frac{dy}{dt}=1,\ \frac{d^2y}{dt^2}=0,\text{ etc.}$$

Hence $$\frac{dy}{dx}=\frac{1}{\frac{dx}{dy}},\quad \frac{d^2y}{dx^2}=-\frac{1}{\left(\frac{dx}{dy}\right)^3}\cdot\frac{d^2x}{dy^2},$$
$$\frac{d^3y}{dx^3}=\frac{1}{\left(\frac{dx}{dy}\right)^5}\left\{3\left(\frac{d^2x}{dy^2}\right)^2-\frac{dx}{dy}\frac{d^3x}{dy^3}\right\},\text{ etc.}$$

The formulæ for the change of the independent variable were given for the first time in the *Traité des infiniment petites* of L'Hôpital. The general theory of transformation was discussed at considerable extent by Euler in his *Calc. Diff.*

In the case of two independent variables, suppose we are given

$$x=\phi(r,\theta),\quad y=\psi(r,\theta).$$

Then $$\frac{dv}{dr}=\frac{dv}{dx}\frac{dx}{dr}+\frac{dv}{dy}\frac{dy}{dr};$$
$$\frac{dv}{d\theta}=\frac{dv}{dx}\frac{dx}{d\theta}+\frac{dv}{dy}\frac{dy}{d\theta}.$$

Hence $$\frac{dv}{dx}=\frac{\frac{dv}{d\theta}\frac{dy}{dr}-\frac{dv}{dr}\frac{dy}{d\theta}}{\frac{dx}{d\theta}\frac{dy}{dr}-\frac{dx}{dr}\frac{dy}{d\theta}};$$
$$\frac{dv}{dy}=\frac{\frac{dv}{d\theta}\frac{dx}{dr}-\frac{dv}{dr}\frac{dx}{d\theta}}{\frac{dx}{dr}\frac{dy}{d\theta}-\frac{dy}{dr}\frac{dx}{d\theta}}.$$

In like manner $\frac{d^2v}{dx^2}, \frac{d^2v}{dy^2}$ can be deduced, but their general values are too complicated for insertion here.

A case which commonly arises is in the transformation from rectangular to polar co-ordinates.

In this case, we have $x=r\cos\theta$, $y=r\sin\theta$, and

$$\frac{dv}{dx}=\cos\theta\frac{dv}{dr}-\frac{\sin\theta}{r}\frac{dv}{d\theta},$$
$$\frac{dv}{dy}=\sin\theta\frac{dv}{dr}+\frac{\cos\theta}{r}\frac{dv}{d\theta}.$$

Hence $\frac{d^2v}{dx^2} = \left(\cos\theta\frac{d}{dr} - \frac{\sin\theta}{r}\frac{d}{d\theta}\right)\left(\cos\theta\frac{dv}{dr} - \frac{\sin\theta}{r}\frac{dv}{d\theta}\right)$

$$= \cos^2\theta\frac{d^2v}{dr^2} + \frac{2\sin\theta\cos\theta}{r}\left(\frac{1}{r}\frac{dv}{d\theta} - \frac{d^2v}{drd\theta}\right)$$

$$+ \frac{\sin^2\theta}{r}\frac{dv}{dr} + \frac{\sin^2\theta}{r^2}\frac{d^2v}{d\theta^2}.$$

The corresponding value of $\frac{d^2v}{dy^2}$ is got by substituting $\frac{\pi}{2}-\theta$ instead of θ in the last equation. Hence we easily find

$$\frac{d^2v}{dx^2} + \frac{d^2v}{dy^2} = \frac{d^2v}{dr^2} + \frac{1}{r}\frac{dv}{dr} + \frac{1}{r^2}\frac{d^2v}{d\theta^2}.$$

95. Another important case, which is of extensive application in geometry, is that of linear transformations.

Let us consider the case of three variables, and suppose

$$x = aX + bY + cZ,\ y = a'X + b'Y + c'Z,\ z = a''X + b''Y + c''Z,$$

then $\frac{dv}{dX} = a\frac{dv}{dx} + a'\frac{dv}{dy} + a''\frac{dv}{dz},$

$$\frac{dv}{dY} = b\frac{dv}{dx} + b'\frac{dv}{dy} + b''\frac{dv}{dz},$$

$$\frac{dv}{dZ} = c\frac{dv}{dx} + c'\frac{dv}{dy} + c''\frac{dv}{dz},$$

$$\frac{d^2v}{dX^2} = \left(a\frac{d}{dx} + a'\frac{d}{dy} + x''\frac{d}{dz}\right)^2 v$$

$$= a^2\frac{d^2v}{dx^2} + 2aa'\frac{d^2v}{dxdy} + 2aa''\frac{d^2v}{dxdz} + 2a'a''\frac{d^2v}{dydz}$$

$$+ a'^2\frac{d^2v}{dy^2} + a''^2\frac{d^2v}{dz^2},$$

. . . .

Again, if we suppose x', y', z' to be transformed by a similar substitution, *i. e.*,

$$x' = aX' + bY' + cZ',\ y' = a'X' + b'Y' + c'Z',\ \text{etc.},$$

then, if any function $u = \phi(x, y, z)$ transform into $\phi_1(X, Y, Z)$, we shall have

$$\phi(x + kx',\ y + ky',\ z + kz') = \phi_1(X + kX',\ Y + kY',\ Z + kZ').$$

If these be expanded, and like powers of k at both sides be equated, we have

$$\left(x'\frac{d}{dx} + y'\frac{d}{dy} + z'\frac{d}{dz}\right)u = \left(X'\frac{d}{dX} + Y'\frac{d}{dY} + Z'\frac{d}{dZ}\right)u.$$

$$\left(x'\frac{d}{dx} + y'\frac{d}{dy} + z'\frac{d}{dz}\right)^2 u - \left(X'\frac{d}{dX} + Y'\frac{d}{dY} + Z'\frac{d}{dZ}\right)^2 u,\ \text{etc.}$$

Consequently the functions $x'\frac{du}{dx} + y'\frac{du}{dy} + z'\frac{du}{dz}$, etc., are unaltered by linear transformation. These functions have important geometrical relations with the original function. Many applications of these principles will be found in Salmon's *Higher Plane Curves*, as also in his *Geometry of Three Dimensions.*

A few additional examples are added for illustration.

(1) If $x = \tan\theta$,

$$\frac{d^2y}{dx^2} + \frac{2x}{1+x^2}\frac{dy}{dx} + \frac{y}{(1+x^2)^2} = 0$$

transforms into

$$\frac{d^2y}{d\theta^2} + y = 0.$$

(2) If z be a function of x and y, and $u = px + qy - z$, prove that when p and q are taken as independent variables we have

$$\frac{du}{dp} = x,\ \frac{du}{dq} = y,\ \frac{d^2u}{dp^2} = \frac{t}{rt - s^2},\ \frac{d^2u}{dpdq} = \frac{-s}{rt - s^2},\ \frac{d^2u}{dq^2} = \frac{r}{rt - s^2},$$

where p, q, r, s, t denote the partial differential coefficients of z with respect to x and y, of the first and second orders.

(3) In the linear transformations in § 95 the determinant $(ab'c'')$ is called the *modulus* of transformation, and the transformation is said to be *orthogonal* when

$$x^2 + y^2 + z^2 = X^2 + Y^2 + Z^2.$$

In this case the determinant

$$\begin{vmatrix} \frac{d^2u}{dx^2} & \frac{d^2u}{dxdy} & \frac{d^2u}{dxdz} \\ \frac{d^2u}{dxdy} & \frac{d^2u}{dy^2} & \frac{d^2u}{dydz} \\ \frac{d^2u}{dxdz} & \frac{d^2u}{dydz} & \frac{d^2u}{dz^2} \end{vmatrix}$$

is unaltered by the transformation.

Jacobians.

96. We now proceed to a short treatment of a remarkable class of determinants first studied by Jacobi (*De determinantibus functionalibus,* Crelle, 1841), in developing important generalizations of the fundamental principles of the differential and integral calculus.

If $u_1, u_2, u_3, \ldots u_n$ be functions of n independent variables $x_1, x_2, x_3, \ldots x_n$, then the following determinant

$$\begin{vmatrix} \frac{du_1}{dx_1}, & \frac{du_1}{dx_2}, & \frac{du_1}{dx_3}, & \ldots & \frac{du_1}{dx_n} \\ \frac{du_2}{dx_1}, & \frac{du_2}{dx_2}, & \frac{du_2}{dx_3}, & & \frac{du_2}{dx_n} \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \frac{du_n}{dx_1}, & \frac{du_n}{dx_2}, & \frac{du_n}{dx_3}, & & \frac{du_n}{dx_n} \end{vmatrix}$$

was called a *functional determinant* by Jacobi. Such determinants are now more usually known as *Jacobians*, a designation introduced by Professor Sylvester, who largely developed their properties, and gave numerous applications of them in higher algebra, as also in curves and surfaces.

The preceding determinant is frequently represented by the abridged notation

$$\frac{d(u_1, u_2 \ldots u_n)}{d(x_1, x_2 \ldots x_n)}.$$

The following discussion, for brevity, is limited for the most part to the case of three variables, but it can be readily extended to any number.

97. Altering the notation, we suppose u, v, w to represent functions of three independent variables, x, y, z; then (Bertrand, *Liouville's Journal,* 1851), if we attribute to each variable an infinitely small increment, there will result a corresponding increment for each of the functions. If now we choose arbitrarily a number of different systems of increments, there will result a corresponding number of systems of increments for the functions.

Accordingly, representing the increments of x by d_1x, d_2x, d_3x, and similarly for the other variables, we shall have

$$d_1u = \frac{du}{dx}d_1x + \frac{du}{dy}d_1y + \frac{du}{dz}d_1z,$$

$$d_2u = \frac{du}{dx}d_2x + \frac{du}{dy}d_2y + \frac{du}{dz}d_2z,$$

$$d_3u = \frac{du}{dx}d_3x + \frac{du}{dy}d_3y + \frac{du}{dz}d_3z.$$

Consequently, by the fundamental rule for the multiplication of determinants, we shall have

$$\begin{vmatrix} d_1u, & d_1v, & d_1w \\ d_2u, & d_2v, & d_2w \\ d_3u, & d_3v, & d_3w \end{vmatrix} = \begin{vmatrix} d_1x, & d_1y, & d_1z \\ d_2x, & d_2y, & d_2z \\ d_3x, & d_3y, & d_3z \end{vmatrix} \times \begin{vmatrix} \frac{du}{dx} & \frac{du}{dy} & \frac{du}{dz} \\ \frac{dv}{dx} & \frac{dv}{dy} & \frac{dv}{dz} \\ \frac{dw}{dx} & \frac{dw}{dy} & \frac{dw}{dz} \end{vmatrix}.$$

Let the first determinant be represented by (A), the second by (B), and the third, or *Jacobian*, by J, and we get $J = \frac{A}{B}$.

That is to say, the Jacobian is the ratio of the determinant of the system of infinitesimal increments of the functions to that of the increments of the variables.

This may be regarded as a generalization of the definition of the derived function in the case of a single variable.

98. Again, *when the functions* u, v, w *are connected by any relation their Jacobian vanishes.*

For suppose u, v, w to be connected by an equation

$$F(u, v, w,) = 0,$$

for all values of x, y, z; then, since in this case

$$\frac{dF}{dx} = 0,\ \frac{dF}{dy} = 0,\ \frac{dF}{dz} = 0,$$

we have

$$\frac{dF}{du}\frac{du}{dx} + \frac{dF}{dv}\frac{dv}{dx} + \frac{dF}{dw}\frac{dw}{dx} = 0,$$

$$\frac{dF}{du}\frac{du}{dy} + \frac{dF}{dv}\frac{dv}{dy} + \frac{dF}{dw}\frac{dw}{dy} = 0,$$

$$\frac{dF}{du}\frac{du}{dz} + \frac{dF}{dv}\frac{dv}{dz} + \frac{dF}{dw}\frac{dw}{dz} = 0.$$

Consequently, eliminating

$$\frac{dF}{du},\ \frac{dF}{dv},\ \frac{dF}{dw},$$

we get

$$\begin{vmatrix} \frac{du}{dx}, & \frac{du}{dy}, & \frac{du}{dz}, \\ \frac{dv}{dx}, & \frac{dv}{dy}, & \frac{dv}{dz}, \\ \frac{dw}{dx}, & \frac{dw}{dy}, & \frac{dw}{dz}, \end{vmatrix} = 0 .$$

This is an extension of the theorem that when a function of a single variable is constant its derived function is zero.

The converse of the preceding theorem can be established, viz., if $J = 0$, then the functions u, v, w are no longer independent of each other.

These results are readily extended to any number of variables; thus, whenever the functions $u_1, u_2, \ldots u_n$ are connected by a relation, $\frac{d(u_1, u_2, \ldots u_n)}{d(x_1, x_2, \ldots x_n)} = 0$; and conversely.

99. Again, if u, v, w, instead of being given explicitly in terms of x, y, z, be given implicitly, *i.e.*, if they are connected with them by three equations of the form

$$F_1(x, y, z, u, v, w) = 0, \quad F_2(x, y, z, u, v, w) = 0 ,$$
$$F_3(x, y, z, u, v, w) = 0 ,$$

we have, adopting the same notation as before,

$$\frac{dF_1}{dx}d_1x + \frac{dF_1}{dy}d_1y + \frac{dF_1}{dz}d_1z + \frac{dF_1}{du}d_1u + \frac{dF_1}{dv}d_1v + \frac{dF_1}{dw}d_1w = 0 ,$$

or

$$\frac{dF_1}{dx}d_1x + \frac{dF_1}{dy}d_1y + \frac{dF_1}{dz}d_1z = -\frac{dF_1}{du}d_1u - \frac{dF_1}{dv}d_1v - \frac{dF_1}{dw}d_1w ,$$

and similar equations for the increments $d_2x \ldots d_3x$, etc. . . . , as also others derived from the functions F_2, F_3 . . . Hence, as before,

$$\begin{vmatrix} d_1x & d_1y & d_1z \\ d_2x & d_2y & d_2z \\ d_3x & d_3y & d_3z \end{vmatrix} \times \begin{vmatrix} \frac{dF_1}{dx} & \frac{dF_1}{dy} & \frac{dF_1}{dz} \\ \frac{dF_2}{dx} & \frac{dF_2}{dy} & \frac{dF_2}{dz} \\ \frac{dF_3}{dx} & \frac{dF_3}{dy} & \frac{dF_3}{dz} \end{vmatrix}$$

$$= -\begin{vmatrix} d_1u & d_1v & d_1w \\ d_2u & d_2v & d_2w \\ d_3u & d_3v & d_3w \end{vmatrix} . \times \begin{vmatrix} \frac{dF_1}{du} & \frac{dF_1}{dv} & \frac{dF_1}{dw} \\ \frac{dF_2}{du} & \frac{dF_2}{dv} & \frac{dF_2}{dw} \\ \frac{dF_3}{du} & \frac{dF_3}{dv} & \frac{dF_3}{dw} \end{vmatrix}$$

This result, when generalized, may be written as follows:

$$\frac{d(u_1, u_2 \ldots u_n)}{d(x_1, x_2 \ldots x_n)} = (-1)^n \begin{vmatrix} \frac{dF_1}{dx_1} \cdots \frac{dF_1}{dx_n} \\ \frac{dF_2}{dx_1} \cdots \frac{dF_2}{dx_n} \\ \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \\ \frac{dF_n}{dx_1} \cdots \frac{dF_n}{dx_n} \end{vmatrix} \div \begin{vmatrix} \frac{dF_1}{du_1} \cdots \frac{dF_1}{du_n} \\ \frac{dF_2}{du_1} \cdots \frac{dF_2}{du_n} \\ \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \\ \frac{dF_n}{du_1} \cdots \frac{dF_n}{du_n} \end{vmatrix}$$

100. We shall next consider the generalization of the elementary theorem $\frac{dF(u)}{dx} = \frac{dF(u)}{du} \frac{du}{dx}$.

If we suppose ϕ_1, ϕ_2, ϕ_3 to represent functions of u, v, w, while u, v, w are functions of x, y, z, then, adopting the same notation as before, and representing the determinant

$$\begin{vmatrix} d_1\phi_1 & d_1\phi_2 & d_1\phi_3 \\ d_2\phi_1 & d_2\phi_2 & d_2\phi_3 \\ d_3\phi_1 & d_3\phi_2 & d_3\phi_3 \end{vmatrix}$$

by C, we have by § 97

$$\begin{vmatrix} \frac{d\phi_1}{dx} & \frac{d\phi_1}{dy} & \frac{d\phi_1}{dz} \\ \frac{d\phi_2}{dx} & \frac{d\phi_2}{dy} & \frac{d\phi_2}{dz} \\ \frac{d\phi_3}{dx} & \frac{d\phi_3}{dy} & \frac{d\phi_3}{dz} \end{vmatrix} = \frac{C}{B};$$

and similarly

$$\begin{vmatrix} \frac{d\phi_1}{du} & \frac{d\phi_1}{dv} & \frac{d\phi_1}{dw} \\ \frac{d\phi_2}{du} & \frac{d\phi_2}{dv} & \frac{d\phi_2}{dw} \\ \frac{d\phi_3}{du} & \frac{d\phi_3}{dv} & \frac{d\phi_3}{dw} \end{vmatrix} = \frac{C}{A};$$

Hence

$$\begin{vmatrix} \frac{d\phi_1}{dx} & \frac{d\phi_1}{dy} & \frac{d\phi_1}{dz} \\ \frac{d\phi_2}{dx} & \frac{d\phi_2}{dy} & \frac{d\phi_2}{dz} \\ \frac{d\phi_3}{dx} & \frac{d\phi_3}{dy} & \frac{d\phi_3}{dz} \end{vmatrix} = \begin{vmatrix} \frac{d\phi_1}{du} & \frac{d\phi_1}{dv} & \frac{d\phi_1}{dw} \\ \frac{d\phi_2}{du} & \frac{d\phi_2}{dv} & \frac{d\phi_2}{dw} \\ \frac{d\phi_3}{du} & \frac{d\phi_3}{dv} & \frac{d\phi_3}{dw} \end{vmatrix} . \begin{vmatrix} \frac{du}{dx} & \frac{du}{dy} & \frac{du}{dz} \\ \frac{dv}{dx} & \frac{dv}{dy} & \frac{dv}{dz} \\ \frac{dw}{dx} & \frac{dw}{dy} & \frac{dw}{dz} \end{vmatrix}$$

Consequently, the Jacobian of ϕ_1, ϕ_2, ϕ_3 with respect to x, y, z is equal to their Jacobian with respect to u, v, w multiplied by the Jacobian of u, v, w with respect to x, y, z.

This is the required generalization in the case of three variables.

101. Again, if u, v, w be functions of x, y, z, we may regard x, y, z as functions of u, v, w; and it follows immediately that the Jacobian of u, v, w with respect to x, y, z is the reciprocal of the Jacobian of x, y, z with respect to u, v, w; *i.e.*

$$\begin{vmatrix} \frac{du}{dx} & \frac{du}{dy} & \frac{du}{dz} \\ \frac{dv}{dx} & \frac{dv}{dy} & \frac{dv}{dz} \\ \frac{dw}{dx} & \frac{dw}{dy} & \frac{dw}{dz} \end{vmatrix} . \begin{vmatrix} \frac{dx}{du} & \frac{dx}{dv} & \frac{dx}{dw} \\ \frac{dy}{du} & \frac{dy}{dv} & \frac{dy}{dw} \\ \frac{dz}{du} & \frac{dz}{dv} & \frac{dz}{dw} \end{vmatrix} = 1.$$

This, when extended to n variables, is the generalization of the theorem that the derived function of y with respect to x is the inverse of that of x with respect to y.

The preceding demonstrations are readily extended to any number of variables. When generalized for n variables, the results are written in abridged notation thus—

$$\frac{d(\phi_1, \phi_2, \ldots \phi_n)}{d(x_1, x_2, \ldots x_n)} = \frac{d(\phi_1, \phi_2, \ldots \phi_n)}{d(u_1, u_2, \ldots u_n)} \times \frac{d(u_1, u_2, \ldots u_n)}{d(x_1, x_2, \ldots x_n)},$$

and $$\frac{d(u_1, u_2, \ldots u_n)}{d(x_1, x_2, \ldots x_n)} \times \frac{d(x_1, x_2, \ldots x_n)}{d(u_1, u_2, \ldots u_n)} = 1.$$

102. Again, *the Jacobian of any system can be expressed as a monomial.* This result can be established as follows:—

Reverting to our original discussion, it is readily seen that of $2n$ quantities, $x_1, x_2, x_3 \ldots x_n, u_1, u_2, u_3, \ldots u_n$, connected by n equations, when any n are chosen at pleasure the others are capable of determination. Consequently, if $n-1$ of them be supposed to remain invariable, all the others may be regarded as changing simultaneously, and the ratios of their infinitely small increments are determined. Hence we may suppose our n systems of simultaneous increments attributed as in the following table:—

$$\begin{array}{cccccccc} d_1x_1 & d_1x_2 & \ldots & d_1x_n & d_1u_1 & 0 & 0 & . \; 0 \\ 0 & d_2x_2 & \ldots & d_2x_n & d_2u_1 & d_2u_2 & 0 & . \; 0 \\ 0 & 0 & d_3x_3 \, . & d_3x_n & d_3u_1 & d_3u_2 & d_3u_3 & . \; 0 \\ . \; . & . \; . & . \; . & . \; . & . \; . & . \; . & . \; . & . \; . \\ 0 \; . & 0 \; . & 0 \, . \, . & d_nx_n & d_nu_1 & d_nu_2 & \ldots & d_nu_n \end{array}$$

The first line indicates that the first system of increments attributed to $x_1, x_2 \ldots x_n$ are such that $u_2, u_3 \ldots u_n$ do not change; in the second line we suppose that increments of the second system are such that $x_1, u_3 \ldots u_n$ do not change; and so on.

Again, since for these values the determinants A, B, reduce to their diagonal terms, we have, in this case, by § 97,

$$J = \frac{d_1u_1}{d_1x_1} \cdot \frac{d_2u_2}{d_2x_2} \cdot \frac{d_3u_3}{d_3x_3} \cdots \frac{d_nu_n}{d_nx_n} .$$

Also, by what has been stated above, the ratios

$$\frac{d_1u_1}{d_1x_1}, \frac{d_2u_2}{d_2x_2}, \frac{d_3u_3}{d_3x_3} \cdots \frac{d_nu_n}{d_nx_n},$$

can each be determined in this case from the given equations.

Consequently the Jacobian of our system is the continued product of $\frac{du_1}{dx_1}, \frac{du_2}{dx_2}, \ldots \frac{du_n}{dx_n}$.

In order to calculate $\frac{du_1}{dx_1}$ it is necessary to express u_1 as a function of $x_1, u_2, \ldots u_n$; and similarly for u_2, u_3, etc.

103. For example, let it be required to find the Jacobian of the system

$$\begin{aligned} x_1 &= r \cos\theta_1, \\ x_2 &= r \sin\theta_1 \cos\theta_2, \\ x_3 &= r \sin\theta_1 \sin\theta_2 \cos\theta_3, \\ &\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \\ x_{n-1} &= r \sin\theta_1 \sin\theta_2 \ldots \cos\theta_{n-1}, \\ x_n &= r \sin\theta_1 \sin\theta_2 \ldots \sin\theta_{n-1}. \end{aligned}$$

Here, squaring and adding, we get

$$x_1^2 + x_2^2 + \cdots + x_n^2 = r^2.$$

We shall employ this instead of the last equation of the system. Hence, adopting the conditions laid down in § 102, we get

$$\frac{dx_1}{d\theta_1} = -r \sin\theta_1, \ \frac{dx_2}{d\theta_2} = -r \sin\theta_1 \sin\theta_2, \ldots \text{etc.}, \ \frac{dx_n}{dr} = \frac{r}{x_n}.$$

Accordingly, the Jacobian of the system is

$$(-1)^{n-1} \frac{r^n \sin^{n-1}\theta_1 \sin^{n-2}\theta_2 \ldots \sin\theta_{n-1}}{x_n}$$

$$= (-1)^{n-1} r^{n-1} \sin^{n-2}\theta_1 \sin^{n-3}\theta_2 \ldots \sin\theta_{n-2}.$$

104. Again, suppose $u_1, u_2, \ldots u_n$ to be the partial derived functions of a given function of the variables $x_1, x_2, \ldots x_n$; *i.e.*, let

$$u_1 = \frac{df}{dx_1}, \ u_2 = \frac{df}{dx_2}, \ \ldots \ u_n = \frac{df}{dx_n}.$$

The Jacobian becomes

$$\begin{vmatrix} \dfrac{d^2f}{dx_1^2} & \dfrac{d^2f}{dx_1dx_2} & \ldots & \dfrac{d^2f}{dx_1dx_n} \\ \dfrac{d^2f}{dx_2dx_1} & \dfrac{d^2f}{dx_2^2} & & \dfrac{d^2f}{dx_2dx_n} \\ \cdot & \cdot & \cdot & \cdot \\ \dfrac{d^2f}{dx_ndx_1} & \dfrac{d^2f}{dx_ndx_2} & & \dfrac{d^2f}{dx_n^2} \end{vmatrix}.$$

Such a determinant is called the *Hessian* of the function $f(x_1, x_2, \ldots x_n)$, after Hesse, who first introduced such determinants into analysis, applying them in many investigations of fundamental importance in the theory of curves and surfaces.

105. Again, in the Jacobian

$$\frac{d(y_1, y_2 \ldots y_n)}{d(x_1, x_2 \ldots x_n)},$$

if the functions $y_1, y_2, \ldots$ are fractions with the same denominator, *i.e.*, such that

$$y_1 = \frac{u_1}{u}, \quad y_2 = \frac{u_2}{u}, \ \ldots \ y_n = \frac{u_n}{u},$$

we have

$$\begin{aligned} u^2 \frac{dy_1}{dx_k} &= u \frac{du_1}{dx_k} - u_1 \frac{du}{dx_k}, \\ u^2 \frac{dy_2}{dx_k} &= u \frac{du_2}{dx_k} - u_2 \frac{du}{dx_k}, \\ &\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \end{aligned}$$

Hence

$$u^{2n+1} \frac{d(y_1, y_2 \ldots y_n)}{d(x_1, x_2 \ldots x_n)}$$

$$= \begin{vmatrix} u, & 0, & \ldots & 0, \\ u_1, & u\dfrac{du_1}{dx_1} - u_1\dfrac{du}{dx_1} & \ldots & u\dfrac{du_1}{dx_n} - u_1\dfrac{du}{dx_n} \\ \cdot & \cdot & \cdot & \cdot \\ u_n, & u\dfrac{du_n}{dx_1} - u_n\dfrac{du}{dx_1} & \ldots & u\dfrac{du_n}{dx_n} - u_n\dfrac{du}{dx_n} \end{vmatrix}.$$

From this, by elementary properties of determinants, we get

$$u^{2n+1} \frac{d(y_1, y_2 \ldots y_n)}{d(x_1, x_2 \ldots x_n)} = \begin{vmatrix} u, & u\dfrac{du}{dx_1} & \ldots & u\dfrac{du}{dx_n} \\ u_1, & u\dfrac{du_1}{dx_1} & \ldots & u\dfrac{du_1}{dx_n} \\ \cdot & \cdot & \cdot & \cdot \\ u_n, & u\dfrac{du_n}{dx_1} & \ldots & n\dfrac{du_n}{dx_n} \end{vmatrix}.$$

Hence

$$\frac{d(y_1, y_2, \ldots y_n)}{d(x_1, x_2, \ldots x_n)} = \frac{1}{u^{n+1}} \begin{vmatrix} u & u_1 & \ldots & u_n \\ \dfrac{du}{dx_1} & \dfrac{du_1}{dx_1} & \ldots & \dfrac{du_n}{dx_1} \\ \cdot & \cdot & \cdot & \cdot \\ \dfrac{du}{dx_n} & \dfrac{du_1}{dx_n} & \ldots & \dfrac{du_n}{dx_n} \end{vmatrix}.$$

This latter determinant has been denoted by

$$K(u, u_1 \ldots u_n).$$

It possesses interesting properties. For example, if $u, u_1, \ldots u_n$ are connected by any homogeneous relation, then

$$K(u, u_1, \ldots u_n) = 0.$$

This follows from § 98, since the quantities $y_1, y_2, \ldots y_n$ are in this case connected by an equation.

It is seen without difficulty that Jacobians and Hessians are covariants. That is, if the functions be transformed by linear substitution (§ 95), the Jacobian of the transformed functions is equal to the original Jacobian multiplied by the modulus of transformation; and similarly the Hessian of the transformed function is equal to that of the original function multiplied by the square of the modulus. It can also be seen that, when the transformation is *orthogonal*, the Jacobian and Hessian are unaltered by the transformation.

PART II.

INTEGRAL CALCULUS.

106. The integral calculus may be said to have taken its origin from the methods employed by Cavalieri, Wallis, and others, for the determination of the quadrature of curves and the cubature of surfaces. These methods, as we have seen, consisted in the division of the required area, or volume, into an indefinite number of thin slices, or "elements;" and then from the law connecting their successive values the sum of all the elements was determined—or rather the "limit" to which that sum approached when the number of elements was indefinitely increased. The processes thus employed were developed and reduced to a suitable notation by Newton and Leibnitz. Thus, adopting the more modern nomenclature, if $\phi(x)$ be a function of x which is finite for all values of x between the limits x_0 and X, and if we suppose the interval $X - x_0$ divided into n parts, $x_1 - x_0$, $x_2 - x_1$, $x_3 - x_2$, $\ldots X - x_{n-1}$, then multiplying each element by the corresponding value of the function, *i.e.*, $x_1 - x_0$ by $\phi(x_0)$ etc., the sum

$$\begin{aligned} S = (x_1 - x_0)\,\phi(x_0) + (x_2 - x_1)\phi\,(x_1) \ldots \\ + (X - x^{n-1})\phi\,(x^{n-1}) \end{aligned}$$

has, by elementary algebra, a finite value, which may be represented by $(X = x_0)\ \phi(\xi)$, where $\phi(\xi)$ lies between the greatest and the least value $\phi(x)$ admits of between the limits.

If, now, we suppose the number of elements increased beyond limit, so that $x_1 - x_0$, $x_2 - x_1$, etc., may be regarded as each becoming indefinitely small, then ultimately the value of S attains to a certain limit, which depends only on the form of the function $\phi(x)$, and on the extreme values X and x_0. In this stage, introducing the symbol of integration $\int$, and adopting the notation $\int_{x_0}^{X} \phi(x)dx$, instead of S, we write

$$\int^{X} \phi(x)dx = \text{lim.} \Big[(x_1 - x_0)\phi(x_0) + (x_2 - x_1)\phi(x)_1 + \ldots$$

$$+ (X - x_{n-1})\phi(x_{n-1}) \Big] = (X - x_0)\phi \Big\{ x_0 + \theta(X - x_0) \Big\},$$

in which θ lies between 0 and 1.

For greater simplicity, it is usual to suppose that the increments $x_1 - x_0$, $x_2 - x_1 \ldots X - x_{n-1}$ are all equal. In this case their common value h is equal to the fraction $\dfrac{X - x_0}{n}$; and S becomes

$$h\{f(x_0) + f(x_0 + h) + f(x_0 + 2h) + \ldots + f(X - 2h) + f(X - h)\}$$

Again $f\{x_0 + \theta\,(X - x_0)\}$ represents the *mean* value of $f(x)$, as x proceeds by equal infinitesimal increments from the value x_0 to X. The application of the integral calculus to the solution of questions on mean or average values is founded on the result here given. Thus, denoting the mean value of $\phi(x)$, between the limits X and x_0 by $M\phi(x)$, we have

$$M\phi(x) = \frac{1}{X - x_0} \int_{x_0}^{X} \phi(x)dx.$$

107. If in the definite integral $\int_{x_0}^{X} \phi(x)dx$ the upper limit X be conceived to vary, x_0 remaining constant, the integral itself will vary; and if we replace X, regarded as variable, by x, the integral may be regarded as a new function, F(x), of x, determined by the equation

$$F(x) = \int^{x} \phi(x)dx = (x - x_0)\phi\Big[x_0 + \theta(x - x_0)\Big].$$

This function vanishes when $x = x_0$; $\therefore F(x_0) = 0$.

Also, by the differential calculus (§ 46) we have

$$\mathrm{F}(x) = (x - x_0)\mathrm{F}'\Big[x_0 + \theta(x - x_0)\Big].$$

Consequently

$$\phi\Big[x_0 + \theta(x - x_0)\Big] = \mathrm{F}'\Big[x_0 + \theta(x - x_0)\Big].$$

Again, making $x = x_0$, we get

$$\phi(x_0) = \mathrm{F}'(x_0)\,;$$

and, since x_0 may have any value, we have in general

$$\phi(x) = \mathrm{F}'(x)\,.$$

Accordingly we may write

$$\int_{x_0}^{\mathrm{X}} \mathrm{F}'(x)dx = \mathrm{F}(\mathrm{X}) - \mathrm{F}(x_0)\,.$$

Hence the process of integration is reduced to the determination of a function $\mathrm{F}(x)$ when its derived function $\mathrm{F}'(x)$ is known.

We shall illustrate these preliminary remarks by one or two examples.

Ex. 1. Find the limit of the sum of the series

$$\frac{n}{n^2 + 1^2} + \frac{n}{n^2 + 2^2} \cdot\cdot\cdot + \frac{n}{2n^2}\,,$$

when n is indefinitely increased.

Let $dx = \dfrac{1}{n}$, and the limit of the series is easily seen to be represented by

$$\int_0^1 \frac{dx}{1 + x^2}, \text{ or is } \frac{\pi}{4} \text{ since } \frac{d}{dx}\,(\tan^{-1}x) = \frac{1}{1 + x^2}\,.$$

Ex. 2. Find the limit of the sum

$$\frac{1}{\sqrt{n^2 - 1^2}} + \frac{1}{\sqrt{n^2 - 2^2}} + \frac{1}{\sqrt{n^2 - 3^2}} \cdot \cdot \cdot + \frac{1}{\sqrt{n^2 - (n-1)^2}}\,,$$

when n is indefinitely increased.

Here the required limit $= \displaystyle\int_0^1 \frac{dx}{\sqrt{1 - x^2}} = \frac{\pi}{2}\,.$

108. We might have started from the preceding result as the definition of the integral calculus, and regarded this calculus as the inverse of the differential. Thus, as in the differential calculus we investigate the rules for proceeding from any primitive function $\mathrm{F}(x)$ to its derived function $\mathrm{F}'(x)$, so in the integral calculus our object is the converse, viz., to determine $\mathrm{F}(x)$, when $\mathrm{F}'(x)$ is given; or, in the language of Newton, "to find the fluent of a given fluxion."

It may be here remarked that it has been shown from geometrical considerations, in § 23, that such a function always exists.

In the differential calculus rules have been laid down for the method of determining the differential of any function. There are, however, no direct rules for the inverse process, exact by retracing the steps by which the derived has been deduced from the original function.

Accordingly, the integral calculus is based on the differential, and to each result in the differential calculus corresponds another in the integral. Moreover, as $\mathrm{F}(x)$ and $\mathrm{F}(x) + \mathrm{C}$ (where C is any arbitrary quantity that does not vary with x) have the same differential, it follows that to find the general integral of $\mathrm{F}'(x)dx$ we must add an arbitrary constant to $\mathrm{F}(x)$.

109. The following elementary integrals (omitting arbitrary constants) are easily arrived at, and are called fundamental integrals, to which all others that admit of integration in finite terms are ultimately reducible—excluding higher transcendental functions:—

$$\int x^n dx = \frac{x^{n+1}}{n+1}, \quad \int \frac{dx}{x} = \log x,$$

$$\int \sin x\, dx = -\cos x, \qquad \int \cos x\, dx = \sin x,$$

$$\int \frac{dx}{\cos^2 x} = \tan x\,, \quad \int \frac{dx}{\sin^2 x} = -\cot x\,,$$

$$\int \frac{dx}{\sqrt{a^2 - x^2}} = \sin^{-1}\frac{x}{a}, \quad \int \frac{dx}{\sqrt{a^2 + x^2}} = \log\,(x + \sqrt{a^2 + x^2}),$$

$$\int \frac{dx}{a^2 + x^2} = \frac{1}{a}\tan^{-1}\frac{x}{a}, \quad \int a^x dx = \frac{a^x}{\log a}\,.$$

110. A number of integrals can readily be reduced to one or other of the above forms. A few elementary cases, such as frequently occur in practice, are here given. We commence with the integral

(1) $$\int \frac{dx}{(x - \alpha)(x - \beta)}\,.$$

Here $$\frac{1}{(x - \alpha)(x - \beta)} = \frac{1}{\alpha - \beta}\left(\frac{1}{x - \alpha} - \frac{1}{x - \beta}\right).$$

$$\therefore \int \frac{dx}{(x - \alpha)(x - \beta)} = \frac{1}{\alpha - \beta}\log\frac{x - \alpha}{x - \beta}.$$

(2) More generally, the integral

$$\int \frac{dx}{a + 2bx + cx^2}$$

may be written in the form

$$\int \frac{c\,dx}{(cx + b)^2 + ac - b^2}\,,$$

or, substituting z for $cx + b$,

$$\int \frac{dz}{z^2 + ac - b^2}\,.$$

The form of this integral depends on the sign of $ac - b^2$.

If $ac - b^2 > 0$, we have

$$\int \frac{dx}{a + 2bx + cx^2} = \frac{1}{\sqrt{ac - b^2}}\tan^{-1}\frac{cx + b}{\sqrt{ac - b^2}}.$$

If $ac - b^2 = 0$,

$$\int \frac{dx}{a + 2bx + cx^2} = \frac{-1}{cx + b}\,.$$

If $ac - b^2 < 0$, the integral comes under (1), and we have

$$\int \frac{dx}{a + 2bx + cx^2} = \frac{1}{2\sqrt{b^2 - ac}}\log\frac{cx + b - \sqrt{b^2 - ac}}{cx + b + \sqrt{b^2 - ac}}\,.$$

(3) Again, since

$$\frac{l + mx}{a + 2bx + cx^2} = \frac{m}{c}\,\frac{b + cx}{a + 2bx + cx^2} + \frac{lc - mb}{c}\,\frac{1}{a + 2bx + cx^2}$$

we have

$$\int \frac{(l + mx)dx}{a + 2bx + cx^2} = \frac{m}{c}\int \frac{(b + cx)dx}{a + 2bx + cx^2} + \frac{lc - mb}{c}\int \frac{dx}{a + 2bx + cx^2}.$$

The integral of $\dfrac{(b + cx)dx}{a + 2bx + cx^2}$ is $\frac{1}{2}\log\,(a + 2bx + cx^2)$, and the latter integral has been obtained in (2).

(4) Next, to find $$\int \frac{dx}{\sin x \cos x}\,.$$

Here

$$\int \frac{dx}{\sin x \cos x} = \int \frac{1}{\tan x}\,\frac{dx}{\cos^2 x} = \int \frac{d(\tan x)}{\tan x} = \log\,(\tan x)\,.$$

In like manner,

(5) $$\int \frac{dx}{\sin x} = \int \frac{d\left(\dfrac{x}{2}\right)}{\sin\dfrac{x}{2}\cos\dfrac{x}{2}} = \log\left(\tan\frac{x}{2}\right)\cdot$$

Hence we get $$\int \frac{dx}{\cos x} = \log\,.\,\tan\left(\frac{x}{2} + \frac{\pi}{4}\right)\cdot$$

(6) Again $\int \tan^2 x\, dx = \int \sec^2 x\, dx - \int dx = \tan x - x.$

111. The number of independent fundamental formulæ must ultimately be the same as the number of independent kinds of functions in analysis. The ordinary elementary functions may be briefly classed as follows: (1) algebraic functions, powers and roots, such as x^m, for fixed numerical values of m, etc.; (2) trigonometrical functions, $\sin x$, $\tan x$, etc., and their inverse functions, circular functions, $\sin^{-1}x$, $\tan^{-1}x$, etc.; (3) exponentials a^x, etc., and their inverse functions, logarithms.

Several other transcendental functions have been introduced into analysis, such as elliptic and hyper-elliptic functions, gamma-functions, and others. We propose subsequently to give a short account of the elementary properties of some of these functions.

112. The reduction of an integration to one or more of the preceding elementary forms is usually effected by one or other of the following methods: (1) transformation to a new variable; (2) integration by parts; (3) decomposition into partial fractions; (4) successive reduction; (5) rationalization. Examples of these methods will appear in succeeding paragraphs.

113. The method of integration by *substitution* corresponds to a change of the independent variable. We shall exemplify it by a few simple cases.

Ex. 1. Let $u = \displaystyle\int \frac{x^m dx}{(a + bx)^n}$, m being a positive integer.

Assume $a + bx = z$, and the integral transforms into

$$\frac{1}{b^{m+1}}\int \frac{(z - a)^m dz}{z^n}\,.$$

If $(z - a)^m$ be expanded by the binomial theorem, each term can be separately integrated.

Ex. 2. $$u = \int \frac{dx}{(x+\alpha)\sqrt{a+2bx+cx^2}}.$$

Let $x + \alpha = \frac{1}{z}$, and the integral transforms into

$$-\int \frac{dz}{\sqrt{a' + 2b'z + c'z^2}},$$

where $a' = c$, $b' = b - c\alpha$, $c' = a - 2b\alpha + c\alpha^2$.

Ex. 3. $$u = \int \frac{dx}{(a+cx^2)^{\frac{3}{2}}}.$$

Let $x = \frac{1}{z}$, and we get

$$u = \int \frac{-zdz}{(az^2+c)^{\frac{3}{2}}} = \frac{1}{a(az^2+c)^{\frac{1}{2}}} = \frac{x}{a(a+cx^2)^{\frac{1}{2}}}.$$

Ex. 4. $$u = \int \frac{dx}{(a+2bx+cx^2)^{\frac{3}{2}}}.$$

Here $$u = \int \frac{c^{\frac{3}{2}}dx}{\{ac - b^2 + (cx+b)^2\}^{\frac{3}{2}}}.$$

Let $cx + b = z$, and it transforms into the preceding integral; hence

$$u = \frac{cx+b}{(ac-b^2)(a+2bx+cx^2)^{\frac{1}{2}}}.$$

Ex. 5. $$u = \int \frac{dx}{(a'+c'x^2)(a+cx^2)^{\frac{1}{2}}}.$$

Let $(a+cx^2)^{\frac{1}{2}} = xz$, then

$$\frac{dx}{(a+cx^2)^{\frac{1}{2}}} = \frac{dz}{c - z^2},$$

and the integral transforms into

$$\int \frac{dz}{(a'c - c'a) - a'z^2}.$$

Ex. 6. $$u = \int \frac{dx}{\sqrt{(\alpha - x)(x - \beta)}}.$$

Let $x = \alpha \sin^2\theta + \beta \cos^2\theta$, and we get

$$\frac{dx}{\sqrt{(\alpha - x)(x-\beta)}} = 2d\theta,$$

$$\therefore \int \frac{dx}{\sqrt{(\alpha - x)(x - \beta)}} = 2\theta = 2\sin^{-1}\sqrt{\frac{x-\beta}{\alpha-\beta}}.$$

Ex. 7. $$u = \int \frac{dx}{x}\sqrt{\frac{\alpha^2 - x^2}{x^2 - \beta^2}}.$$

Here $$du = \frac{\alpha^2 dx}{x\sqrt{(\alpha^2 - x^2)(x^2 - \beta^2)}} - \frac{xdx}{\sqrt{(\alpha^2-x^2)(x^2-\beta^2)}}.$$

If we make $x^2 = \frac{1}{z}$ in the former, and $x^2 = y$ in the latter, they each reduce to the preceding example.

Ex. 8. $$\int \frac{dx}{a + b\cos x}.$$

Here $$u = \int \frac{dx}{(a+b)\cos^2\frac{x}{2} + (a-b)\sin^2\frac{x}{2}},$$

$$= \int \frac{\sec^2\frac{x}{2}dx}{a + b + (a-b)\tan^2\frac{x}{2}} = 2\int \frac{dz}{a+b+(a-b)z^2},$$

where $z = \tan\frac{x}{2}$.

This integral is a circular or a logarithmic function, according as $a >$, or, $< b$.

(1) Let $a > b$, and suppose $b = a\cos\alpha$, then we have

$$u = \frac{1}{a}\int \frac{dz}{\cos^2\frac{\alpha}{2} + z^2\sin^2\frac{\alpha}{2}} = \frac{2}{a\sin\alpha}\tan^{-1}\left(\tan\frac{\alpha}{2}\tan\frac{x}{2}\right).$$

(2) If $a < b$, let $a = b\cos\alpha$, then

$$u = \int \frac{dz}{\cos^2\frac{\alpha}{2} - z^2\sin^2\frac{\alpha}{2}}$$

$$= \frac{1}{b\sin\alpha}\log\frac{\cos\frac{\alpha}{2} + \sin\frac{\alpha}{2}\tan\frac{x}{2}}{\cos\frac{\alpha}{2} - \sin\frac{\alpha}{2}\tan\frac{x}{2}},$$

$$= \frac{1}{b\sin\alpha}\log\frac{\cos\frac{\alpha - x}{2}}{\cos\frac{\alpha + x}{2}},$$

(3) If $a = b$, the value of the integral is

$$\frac{1}{a}\tan\frac{x}{2}.$$

114. The substitution of an imaginary expression for a constant in an integral is often useful in evaluating integrals. For example, if in the equation

$$\int e^{ax}dx = \frac{e^{ax}}{a}$$

we substitute[1] $a + i\beta$ for a, it becomes

$$\int e^{ax}(\cos\beta x + i\sin\beta x)dx = \frac{e^{ax}(\cos\beta x + i\sin\beta x)}{\alpha + i\beta}$$
$$= \frac{e^{ax}(\cos\beta x + i\sin\beta x)(\alpha - i\beta)}{\alpha^2 + \beta^2}.$$

Hence, equating the real and also the imaginary parts, we get

$$\int e^{ax}\cos\beta x\,dx = \frac{e^{ax}(\alpha\cos\beta x + \beta\sin\beta x)}{\alpha^2+\beta^2}.$$
$$\int e^{ax}\sin\beta x\,dx = \frac{e^{ax}(\alpha\sin\beta x - \beta\cos\beta x)}{\alpha^2+\beta^2},$$

omitting the arbitrary constants. These results can be easily verified.

115. The method of *integration by parts* depends on the following equation, which is deduced immediately from the relation $d(uv) = udv + vdu$:

$$\int udv = uv - \int vdu.$$

Hence, the determination of the former integral is reduced to that of the latter, and *vice versa*.

Ex. 1. To find

$$\int \tan^{-1}x\,dx.$$

Here

$$\int \tan^{-1}x\,dx = \tan^{-1}x - \int \frac{xdx}{1+x^2} = x\tan^{-1}x - \tfrac{1}{2}\log(1+x^2).$$

Ex. 2. Next to find

$$\int x^n \log x\,dx.$$

Let

$$u = \log x, \quad v = \frac{x^{n+1}}{n+1};$$

then

$$\int x^n\log x\,dx = \frac{x^{n+1}}{n+1}\log x - \int \frac{x^n dx}{n+1} = \frac{x^{n+1}}{n+1}\left(\log x - \frac{1}{n+1}\right).$$

Ex. 3. Again, to find

$$\int \log(x + \sqrt{x^2+a^2})dx.$$

$$\int \log(x+\sqrt{x^2+a^2})dx = x\log(x+\sqrt{x^2+a^2}) - \int \frac{xdx}{\sqrt{x^2+a^2}}$$
$$= x\log(x + \sqrt{x^2+a^2}) - \sqrt{x^2+a^2}.$$

Ex. 4. $$\int (\log x)^n dx.$$

$$\int (\log x)^n dx = x(\log x)^n - n\int (\log x)^{n-1}dx$$

$$= x(\log x)^n - nx(\log x)^{n-1} + n(n-1)\int (\log x)^{n-2}dx.$$

Accordingly, by successive applications of this formula, the integral can be found whenever n is a *positive* integer. If n be a negative integer, the integral finally depends on $\int \frac{dx}{\log x}$, a form to be subsequently considered.

Ex. 5. $$\int x^m(\log x)^n dx.$$

This is at once reduced to the preceding by making $z = x^{m+1}$.

Ex. 6. $$\int x^m e^{ax}dx.$$

This is immediately reducible to Ex. 4 by making $e^{ax} = z$. It can also be deduced directly, since

$$\int x^m e^{ax}dx = \frac{x^m e^{ax}}{a} - \frac{m}{a}\int e^{a}xx^{m-1}dx.$$

Ex. 7. $$\int \frac{e^x x}{(1+x)^2}dx.$$ *Ans.* $\frac{e^x}{1+x}$.

116. In general, if

$$\Theta = u\frac{d^nv}{dx^n} - \frac{du}{dx}\frac{d^{n-1}v}{dx^{n-1}} + \frac{d^2u}{dx^2}\frac{d^{n-2}v}{dx^{n-2}} - \ldots + (-1)^n\frac{d^nu}{dx^n}v$$

---

[1] We shall throughout represent the imaginary symbol $\sqrt{-1}$ by i, according to the usual notation.

we have

$$\int u\frac{d^{n+1}v}{dx^{n+1}}\,dx = \Theta + (-1)^{n+1}\int v\,\frac{d^{n+1}u}{dx^{n+1}}dx\,.$$

This result is readily proved by successive applications of the method of integration by parts, or can at once be verified by differentiation.

As an example, let us consider the integral

$$\int F(x)e^{ax}dx\,,$$

where $F(x)$ represents a rational integer algebraic function of x, of the degree n.

Let $u = F(x)$, and $v = \frac{e^{ax}}{a^{n+1}}$, then $\frac{d^{n+1}u}{dx^{n+1}} = 0$;

consequently we have

$$\int e^{ax}F(x)dx = \frac{e^{ax}}{a}\left[F(x) - \frac{F'(x)}{a} + \ldots + (-1)^n\frac{F^n(x)}{a^n}\right].$$

This result can be also readily obtained by aid of the symbolic theorem of § 90, thus,

$$\begin{aligned} D^{-1}\,.\,e^{ax}F(x) &= e^{ax}(D+a)^{-1}F(x) \\ &= \frac{e^{ax}}{a}\left(1+\frac{D}{a}\right)^{-1}F(x) \\ &= \frac{e^{ax}}{a}\left[1 - \frac{D}{a} + \frac{D^2}{a^2} - \ldots + (-1)^n\frac{D^n}{a^n}\right]F(x)\,, \end{aligned}$$

the remaining terms being neglected since $D^{n+1}F(x) = 0$. This result plainly coincides with that previously found.

More generally, if $F(x, e^{ax}, e^{bx}, \ldots e^{kx})$ represents a rational integer function of x, e^{ax}, e^{bx}, . . . the integral of

$$F(x, e^{ax}, e^{bx}, \ldots e^{kx})dx$$

can be determined. For, this function, being composed of products of integer positive powers of x, e^{ax}, etc., will consist of a number of terms of the form $Ax^m e^{lax}e^{nb}{}_x \ldots$ or $Ax^m e^{(la+nb+\ldots)x}$, each of which can be integrated by the preceding method.

Again the form

$$\int F(x, \log x)dx,$$

is reducible to

$$\int F(e^z, z)e^z dz,$$

by making $x = e^z$, and consequently, when F represents an integer algebraic function, is integrable by the method considered above.

117. We next proceed to give a brief account of the treatment of the integral $\int\frac{f(x)}{\phi(x)}dx$, in which $f(x)$ and $\phi(x)$ are rational algebraic functions of x.

This class of integrals early engaged the attention of mathematicians. For example, Leibnitz and John Bernoulli, in the *Acta Eruditorum* (1702 and 1703), showed that such integrals depended on the method of *partial fractions.* The processes there given were simplified and generalized by Euler (*Introductio in Analysin Infinitorum*, 1748).

When the degree of $f(x)$ is not less than that of $\phi(x)$, the expression $\frac{f(x)}{\phi(x)}$ can by division be reduced to an integer along with a fractional part; we may, therefore, suppose that we have reduced the degree of $f(x)$ to less than that of $\phi(x)$. Then, a being a simple root of $\phi(x) = 0$, we may assume $\phi(x) = (x-a)\chi(x)$, where $\chi(x)$ is not divisible by $x - a$.

If we now make

$$\frac{f(x)}{\phi(x)} = \frac{A}{x-a} + \frac{f_1(x)}{\chi(x)}\,,$$

we have

$$\frac{f(x)}{\phi(x)} = \frac{A\chi(x) + (x-a)f_1(x)}{(x-a)\chi(x)}\,,$$

$$\therefore\ f(x) = A\chi(x) + (x-a)f_1(x)\,.$$

This gives

$$f_1(x) = \frac{f(x) - A\chi(x)}{x-a}\,.$$

In order that the second member should be an integer expression, $f(x) - A\chi(x)$ must be divisible by $x - a$; hence we get

$$A = \frac{f(a)}{\chi(a)} = \frac{f(a)}{\phi'(a)}.$$

In like manner, if b be a second simple root of $\phi(x) = 0$, and consequently a root of $\chi(x) = 0$, we may make $\chi(x) = (x-b)\psi(x)$. Hence we get

$$\frac{f_1x}{\chi(x)} = \frac{B}{x-b} + \frac{f_2(x)}{\psi(x)}\,;$$

from which it follows that

$$B = \frac{f(b)}{\phi'(b)}\,.$$

Finally if a, b, . . . l represent all the roots of $\phi(x) = 0$, no two of which are equal, we shall have

$$\frac{f(x)}{\phi(x)} = \frac{A}{x-a} + \frac{B}{x-b} + \ldots + \frac{L}{x-l}\,,$$

where $A = \frac{f(a)}{\phi'(a)}$, $B = \frac{f(b)}{\phi'(b)} \ldots L = \frac{f(l)}{\phi'(l)}$.

Hence

$$\int\frac{f(x)}{\phi(x)}dx$$

$$= \frac{f(a)}{\phi'(a)}\log(x-a) + \frac{f(b)}{\phi'(b)}\log(x-b) + \ldots + \frac{f(l)}{\phi'(l)}\log(x-l)\,.$$

In the general case of multiple roots, we may suppose

$$\phi(x) = (x-a)^{\alpha}(x-b)^{\beta} \ldots (x-l)^{\lambda},$$

and assume

$$\begin{aligned} \frac{f(x)}{\phi(x)} = {} & \frac{A_1}{x-a} + \frac{A_2}{(x-a)^2} \ldots + \frac{A_\alpha}{(x-a)^\alpha} \\ & + \frac{B_1}{x-b} + \frac{B_2}{(x-b)^2} \ldots + \frac{B_\beta}{(x-b)^\beta} \\ & \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \\ & + \frac{L_1}{x-l} + \frac{L_2}{(x-l)^2} \ldots + \frac{L_\lambda}{(x-l)^\lambda}\,. \end{aligned}$$

The constants $A_1, A_2 \ldots B_1, B_2 \ldots L_1 \ldots L_\lambda$, can be determined by ordinary algebraic methods, and each term is immediately integrable. The preceding is called the method of integration by decomposition into partial fractions.

The method here given applies also to the case where $\phi(x) = 0$ has imaginary roots. In that case it is usually, however, simpler to employ a somewhat different treatment. Thus, to a pair of imaginary roots $\alpha \pm i\beta$ corresponds a partial fraction of the form

$$\frac{Lx + M}{(x-\alpha)^2 + \beta^2}\,.$$

Also, for n pairs of equal imaginary roots, we have additional terms of the form

$$\frac{L_2x + M_2}{\{(x-\alpha)^2 + \beta^2\}^2}\,, \quad \frac{L_3x + M_3}{\{(x-\alpha)^2 + \beta^2\}^3}\,, \quad \ldots \quad \frac{L_nx + M_n}{\{(x-\alpha)^2 + \beta^2\}^n}\,.$$

Each of these expressions consists of two parts, one of which can be immediately integrated. For example,

$$\frac{(L_nx + M_n)dx}{\{(x-\alpha)^2 + \beta^2\}^n} = \frac{L_n(x-\alpha)dx}{\{(x-\alpha)^2 + \beta^2\}^n} + \frac{(L_n\alpha + M)dx}{\{(x-\alpha)^2 + \beta^2\}^n}\,;$$

the former can be at once found; the consideration of the latter class of expressions is postponed for the present.

Many integrals of the form here considered may be determined by a transformation, without the employment of the method of partial fractions.

For example,

$$\int\frac{x^{n-1}dx}{ax^{2n} + 2bx^n + c}$$

is at once reduced to an elementary form by making $x^n = z$.

Again

$$\int\frac{dx}{(x-a)^m(x-b)^n}$$

is reduced to depend on

$$\int\frac{(1-z)^{m+n-2}}{z^m}\,dz$$

by making $z = \frac{x-a}{x-b}$.

Ex. 1. To find $\int\frac{x^5dx}{x^3-1}$, assume $z = x^3$;

then $x^5dx = \frac{1}{3}zdz$, and we get

$$\int\frac{x^5dx}{x^3-1} = \frac{1}{3}\int\frac{zdz}{z-1} = \frac{1}{3}z + \frac{1}{3}\log(z-1) = \frac{x^3}{3} + \frac{1}{3}\log(x^3-1).$$

Ex. 2. To find $\int\frac{dx}{x(a+bx^n)}$.

Let $x^n = \frac{1}{z}$, then $\frac{dx}{x} = -\frac{1}{n}\,\frac{dz}{z}$,

and

$$\int\frac{dx}{x(a+bx^n)} = -\frac{1}{n}\int\frac{dz}{az+b} = \frac{1}{na}\log\left(\frac{x^n}{a+bx^n}\right).$$

Ex. 3. $\int\frac{dx}{x^4(a+bx^3)}$.

Let $x^3 = \frac{1}{z}$, and we get

$$\int\frac{dx}{x^4(a+bx^3)} = -\tfrac{1}{3}\int\frac{zdz}{az+b} = -\frac{z}{3a}+\frac{b}{3a^2}\log(az+b)$$
$$= -\frac{1}{3ax^3}+\frac{b}{3a^2}\log\left(\frac{a+bx^3}{x^3}\right).$$

Ex. 4. To find $\displaystyle\int\frac{dx}{1-2x^2\cos\theta+x^4}$.

Here
$$\int\frac{dx}{1-2x^2\cos\theta+x^4}$$
$$=\int\frac{dx}{(1+2x\cos\frac{1}{2}\theta+x^2)\,(1-2x\cos\frac{1}{2}\theta+x^2)}$$
$$=\frac{1}{4\cos\frac{1}{2}\theta}\int\frac{(x+2\cos\frac{1}{2}\theta)dx}{1+2x\cos\frac{1}{2}\theta+x^2}$$
$$-\frac{1}{4\cos\frac{1}{2}\theta}\int\frac{(x-2\cos\frac{1}{2}\theta)dx}{1-2x\cos\frac{1}{2}\theta+x^2}$$
$$=\frac{1}{8\cos\frac{1}{2}\theta}\log\frac{1+2x\cos\frac{1}{2}\theta+x^2}{1-2x\cos\frac{1}{2}\theta+x^2}$$
$$+\frac{1}{4\sin\frac{1}{2}\theta}\left\{\tan^{-1}\frac{x+\cos\frac{1}{2}\theta}{\sin\frac{1}{2}\theta}+\tan^{-1}\frac{x-\cos\frac{1}{2}\theta}{\sin\frac{1}{2}\theta}\right\}$$
$$=\frac{1}{8\cos\frac{1}{2}\theta}\log\frac{1+2x\cos\frac{1}{2}\theta+x^2}{1-2x\cos\frac{1}{2}\theta+x^2}$$
$$+\frac{1}{4\sin\frac{1}{2}\theta}\tan^{-1}\frac{2x\sin\frac{1}{2}\theta}{1-x^2}.$$

Ex. 5. Find the integral of
$$\frac{dx}{a+2bx^2+cx^4}$$
when $\qquad ac>b^2.$

It is easily seen from the last that its value may be written
$$\frac{1}{8\kappa\sqrt{a}}\log\frac{\sqrt{a}+2\kappa x+x^2\sqrt{c}}{\sqrt{a}-2\kappa x+x^2\sqrt{c}}$$
$$+\frac{1}{4\sqrt{a(b+\kappa^2)}}\tan^{-1}\frac{2x\sqrt{b+\kappa^2}}{\sqrt{a}-x^2\sqrt{c}},$$
where
$$\kappa=\sqrt{\frac{\sqrt{ac}-b}{2}}.$$

118. Several general classes of integrals can be easily reduced by a transformation to depend on those of the preceding article.

For example, the integral
$$\int f(e^{ax})dx$$
reduces to $\int f(z)\frac{dz}{z}$, by making $e^{ax}=z$; and, accordingly, it can be integrated whenever $f(z)$ is a rational algebraic function of z.

Again, if we take $\tan\frac{1}{2}x=z$, we get
$$\sin x=\frac{2z}{1+z^2},\ \cos x=\frac{1-z^2}{1+z^2},\ dx=\frac{2dz}{1+z^2},$$
and, the expression
$$f(\sin x,\cos x)dx,$$
transforms into
$$f\left(\frac{2z}{1+z^2},\ \frac{1-z^2}{1+z^2}\right)\frac{2dz}{1+z^2}.$$

Consequently, whenever $f(\sin x, \cos x)$ is a rational function, the integration of $f(\sin x, \cos x)dx$ is reducible by the method of partial fractions.

119. Functions of this latter class are, however, usually more readily integrated by other processes. Thus, when $f(\sin x, \cos x)$ is a rational and integer function, its integration depends on that of the sum of a number of expressions of the form $\sin^m x\cos^n x\,dx$. As a number of other forms are readily reducible to this type, it is proposed to devote a short space to its discussion here.

In the first place it should be observed that whenever m or n is an odd integer, the expression $\sin^m x\cos^n x\,dx$ can be immediately integrated. For, if we suppose $n=2r+1$, the integral transforms into
$$\int z^m(1-z^2)^r dz,$$
by making $z=\sin x$. Hence, as r is by hypothesis a positive integer, $(1-z^2)^r$ can be expanded in a finite number of terms, and the integral thus immediately obtained.

Again, if $m+n$ be an even negative integer, the expression can be readily integrated; for, by assuming $z=\tan x$, we get
$$\int\sin^m x\cos^n x dx=\int z^m\left(1+z^2\right)^{\frac{m+n}{2}-1}dz.$$
This integral can be readily obtained by expansion.

120. When neither of these methods is applicable it is usual to find the integral of $\sin^m x\cos^n x dx$ by the method of successive reduction.

The formulæ of reduction can be easily obtained by the method of integration by parts; thus
$$\int\sin^m x\cos^n x dx=\int\cos^{n-1}x\sin^m x d(\sin x)$$
$$=\int\frac{\cos^{n-1}x}{m+1}d(\sin^{m+1}x)=\frac{\cos^{n-1}x\sin^{m+1}x}{m+1}+\frac{n-1}{m+1}$$
$$\int\sin^{m+2}x\cos^{n-2}x dx.$$

Again, $\int\sin^{m+2}x\cos^{n-2}x dx=\int\sin^m x(1-\cos^2 x)\cos^{n-2}x dx$
$=\int\sin^m x\cos^{n-2}x dx-\int\sin^m x\cos^n x dx.$

Substituting in the former equation, and transposing the latter integral to the other side of the equation, we get
$$\int\sin^m x\cos^n x dx=\frac{\sin^{m+1}x\cos^{n-1}x}{m+n}+\frac{n-1}{m+n}$$
$$\int\sin^m x\cos^{n-2}x dx.$$

Hence, when n is positive, the integral of $\sin^m x\cos^n xdx$ depends on that of $\sin^m x\cos^{n-2}x dx$. The corresponding formulæ in which the degree of $\sin x$ is reduced can be immediately found.

It should be noted that these formulæ of reduction are perfectly general, and hold whether m and n be positive or negative, integer or fractional. Accordingly, changing the sign of m, our first equation may be written thus:—
$$\int\frac{\cos^n x}{\sin^m x}dx=-\frac{\cos^{n-1}x}{(m-1)\sin^{m-1}x}-\frac{n-1}{m-1}\int\frac{\cos^{n-2}x}{\sin^{m-2}x}dx.$$

121. These formulæ of reduction, as well as many others, can be readily established by differentiation. For example, since
$$\frac{d}{dx}(\sin^m x\cos^n x)=m\sin^{m-1}x\cos^{n+1}x-n\sin^{m+1}x\cos^{n-1}x$$
$$=m\sin^{m-1}x\cos^{n-1}x-(m+n)\sin^{m+1}x\cos^{n-1}x,$$
the integration of the expression $\sin^{m+1}x\cos^{n-1}xdx$ depends on that of $\sin^{m-1}x\cos^{n-1}xdx$; and similarly in other cases.

It may be noted that the integral (§ 118)
$$\int\frac{dx}{\{(x-\alpha)^2+\beta^2\}^n}$$
is at once reduced to the class here considered by making $x-\alpha=\beta\tan\theta$, when it becomes
$$\frac{1}{\beta^{2n-1}}\int\cos^{2n-2}\theta d\theta.$$

To find $\qquad\int\tan^n xdx.$

Here $\qquad\int\tan^n xdx=\int\tan^{n-2}x(\sec^2 x-1)dx$
$$=\frac{\tan^{n-1}x}{n-1}-\int\tan^{n-2}xdx$$
$$=\frac{\tan^{n-1}x}{n-1}-\frac{\tan^{n-3}x}{n-3}+\text{etc.}$$

Next, let us consider the integral
$$\int\frac{dx}{(a\cos x+b\sin x)^n}.$$

Let $\tan\alpha=\frac{a}{b}$, and we get
$$a\cos x+b\sin x=(a^2+b^2)^{\frac{1}{2}}\sin(x+\alpha).$$

Hence, making $x+\alpha=z$, the integral transforms into
$$(a^2+b^2)^{-\frac{n}{2}}\int\frac{dz}{\sin^n z}.$$

122. In many applications the results depend on integrals of the form here discussed when taken between the limits 0 and $\frac{\pi}{2}$. Such definite integrals are easily found when the indices m and n are positive integers.

Commencing with the simple case of $\int_0^{\frac{\pi}{2}}\sin^n xdx$, we have, since $\sin x \cos^{n-1}x$ vanishes for both limits,

$$\int_0^{\frac{\pi}{2}} \cos^n x dx = \frac{n-1}{n}\int_0^{\frac{\pi}{2}} \cos^{n-2}x dx.$$

By successive applications of this formula the definite integral in question can be always found when n is a positive integer; its form, however, depends on whether the index n is even or odd.

(1) Suppose n even, and equal to $2r$,

then $$\int_0^{\frac{\pi}{2}} \cos^{2r}x dx = \frac{2r-1}{2r}\int_0^{\frac{\pi}{2}} \cos^{2r-2}x dx,$$

and, accordingly, by successive applications, we get

$$\int_0^{\frac{\pi}{2}} \cos^{2r}x dx = \frac{1\,.\,3\,.\,5\,.\,.\,.\,(2r-1)}{2\,.\,4\,.\,6\,.\,.\,.\quad 2r}\,\frac{\pi}{2}.$$

(2) If n be odd, and equal to $2r+1$, we get in like manner

$$\int_0^{\frac{\pi}{2}} \cos^{2r+1}x dx = \frac{2\,.\,4\,.\,6\,.\,.\,.\quad 2r}{3\,.\,5\,.\,7\,.\,.\,.\,(2r+1)}$$

It is evident that in all cases

$$\int_0^{\frac{\pi}{2}} \sin^n x dx = \int_0^{\frac{\pi}{2}} \cos^n x dx.$$

(3) In like manner, we have

$$\int_0^{\frac{\pi}{2}} \sin^m x \cos^n x dx = \frac{n-1}{m+n}\int_0^{\frac{\pi}{2}} \sin^m x \cos^{n-2}x dx.$$

As in the former case, the value of this definite integral depends on whether the indices are odd or even.

First suppose n odd, and equal $2r+1$,

then

$$\int_0^{\frac{\pi}{2}} \sin^m x \cos^{2r+1}x dx = \frac{2r}{m+2r+1}\int_0^{\frac{\pi}{2}} \sin^m x \cos^{2r-1}x dx.$$

Hence $$\int_0^{\frac{\pi}{2}} \sin^m x \cos^{2r+1}x dx$$

$$= \frac{2r(2r-2)\,.\,.\,.\,2}{(2r+m+1)(2r+m-1)\,.\,.\,.\,(m+3)}\int_0^{\frac{\pi}{2}} \sin^m x \cos x dx$$

$$= \frac{2\,.\,4\,.\,6\,.\,.\,.\,2r}{(m+1)(m+3)\,.\,.\,.\,(m+2r+1)}.$$

Next let n be even, and equal to $2r$, then

$$\int_0^{\frac{\pi}{2}} \sin^{2m}x \cos^{2r}x dx = \frac{2r-1}{2(m+r)}\int_0^{\frac{\pi}{2}} \sin^{2m}x \cos^{2r-2}x dx.$$

Hence as before,

$$\int_0^{\frac{\pi}{2}} \sin^{2m}x \cos^{2r}x dx$$

$$= \frac{1\,.\,3\,.\,5\,.\,.\,.\,(2r-1)}{(2m+2)\,.\,.\,.\,(2m+2r)}\int_0^{\frac{\pi}{2}} \sin^{2m}x dx$$

$$= \frac{1\,.\,3\,.\,5\,.\,.\,.\,(2r-1)\,.\,1\,.\,3\,.\,5\,.\,.\,.\,(2m-1)}{2\,.\,4\,.\,6\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,.\,(2m+2r)}\,.\,\frac{\pi}{2}.$$

When m and n are both fractional these definite integrals are reducible to Eulerian integrals,—functions of which a short discussion will be subsequently given.

The following examples are given for the purpose of illustrating the preceding results.

Ex. 1. $\int_0^1 (1-x^2)^m dx$, where m is an integer.

Ans. $\dfrac{2\,.\,4\,.\,6\,.\,.\,.\,(2m)}{3\,.\,5\,.\,7\,.\,.\,.\,(2m+1)}$.

Ex. 2. $\int_0^{\frac{\pi}{2}} \cos^5 x \sin^{\frac{2}{3}}x dx$, *Ans.* $\dfrac{3\,.\,6\,.\,12}{5\,.\,11\,.\,17}$.

Ex. 3. $\int_0^{\infty} \dfrac{dx}{(a^2+x^2)^n}$, where n is an integer.

Ans. $\dfrac{\pi}{2a^{2n-1}}\,.\,\dfrac{1\,.\,3\,.\,5\,.\,.\,.\,(2n-3)}{2\,.\,4\,.\,6\,.\,.\,.\,(2n-2)}$.

Ex. 4. $\int_0^{\frac{\pi}{2}} \cos^{n+2r}x \cos nx\, dx$.

Ans. $\dfrac{\pi}{2^{n+2r+1}}\;\dfrac{(n+2r)\,(n+2r-1)\,.\,.\,.\,(n+r+1)}{1\,.\,2\,.\,3\quad .\,.\,.\quad r}$.

Ex. 5. To deduce Wallis's value for π by aid of the definite integrals considered in this article.

When m is positive, we have, for all values of x between 0 and $\frac{\pi}{2}$, $\sin^{2m-1}x > \sin^{2m}x > \sin^{2m+1}x$; accordingly,

$$\int_0^{\frac{\pi}{2}} \sin^{2m-1}x dx > \int_0^{\frac{\pi}{2}} \sin^{2m}x dx > \int_0^{\frac{\pi}{2}} \sin^{2m+1}x dx,$$

$$\therefore\ \frac{1\,.\,3\,.\,5\,.\,.\,.\,(2m-1)}{2\,.\,4\,.\,6\,.\,.\,.\quad 2m}\,\frac{\pi}{2} \text{ lies between}$$

$$\frac{2\,.\,4\,.\,6\,.\,.\,.\,(2m-2)}{3\,.\,5\,.\,7\,.\,.\,.\,(2m-1)} \text{ and } \frac{2\,.\,4\,.\,6\,.\,.\,.\quad 2m}{3\,.\,5\,.\,7\,.\,.\,.\,(2m+1)};$$

but when m is indefinitely increased the latter fractions tend to equality, and, consequently, we have the well-known formula of Wallis, viz.:—

$$\frac{\pi}{2} = \text{limit of } \frac{2\,.\,2}{1\,.\,3}\,.\,\frac{4\,.\,4}{3\,.\,5}\,.\,\frac{6\,.\,6}{5\,.\,7}\,.\,.\,.$$

123. As a further example of the method of successive reduction, we shall consider the integral

$$\int x^{m-1}(1-x)^{n-1}dx.$$

Here, integrating by parts, we have

$$\int x^{m-1}(1-x)^{n-1}dx = \frac{x^m(1-x)^{n-1}}{m} + \frac{n-1}{m}\int x^m(1-x)^{n-2}dx.$$

Again,

$$\int x^m(1-x)^{n-2}dx = \int x^{m-1}(1-x)^{n-2}dx - \int x^{m-1}(1-x)^{n-1}dx.$$

Substituting, and transposing, we get

$$\int x^{m-1}(1-x)^{n-1}dx = \frac{x^m(1-x)^{n-1}}{m+n-1}$$

$$+ \frac{n-1}{m+n-1}\int x^{m-1}(1-x)^{n-2}dx.$$

By successive applications of this relation the proposed integral can be found whenever n is a positive integer. It can be determined in like manner when m is a positive integer. The integral of $x^m(a+bx)^n dx$ readily admits of similar treatment.

The preceding is a simple case of the integration of what are styled *binomial differentials, i.e.*, differentials of the form $x^m(a+bx^n)^{\frac{p}{q}}dx$,—in which m, n, p, q represent any numbers, positive or negative. We propose to determine in what cases such differentials can be immediately integrated by a transformation.

Assume $a + bx^n = z^q$, then $x = \left(\dfrac{z^q-a}{b}\right)^{\frac{1}{n}}$, and we get

$$x^m(a+bx^n)^{\frac{p}{q}}\,dx = \frac{q}{nb^{\frac{m+1}{n}}}\,z^{p+q-1}(z^q-a)^{\frac{m-n+1}{n}}dz.$$

The latter can be immediately integrated when $\dfrac{m+1}{n}$ is an integer.

Again, substituting $\dfrac{1}{z}$ for x, the expression $x^m(a+bx^n)^{\frac{p}{q}}dx$ becomes $-z^{-m-n\frac{p}{q}-2}\,.\,(az^n+b)^{\frac{p}{q}}dz$. This can be integrated whenever $\dfrac{m+1}{n}+\dfrac{p}{q}$ is an integer.

It can be shown that when neither of these conditions is fulfilled the integral of the binomial differential cannot be expressed except by infinite series.

124. *Irrational Functions.*—We shall next briefly consider the method of proceeding in the case of *irrational* expressions.

Suppose $F(x, \sqrt{X})dx$ to represent the expression whose integration is sought, where F is a rational algebraic function, and X is a rational integer polynomial of any degree in x. Here, since even powers of $\sqrt{X}$ are rational and odd powers contain $\sqrt{X}$ as a factor, it is plain that $F(x, \sqrt{X})$ can be always reduced to the form

$$\frac{P+Q\sqrt{X}}{P'+Q'\sqrt{X}},$$

where P, Q, P′, Q′ are rational algebraic functions of x. Again, if this be multiplied by $P'-Q'\sqrt{X}$, it is reducible to the form

$$M+N\sqrt{X}, \text{ or to } M+\frac{NX}{\sqrt{X}}$$

where M and N are rational functions. Consequently integrals of the proposed form are reducible in general to two parts, of which one is rational, and the other is of the form

$$\int\frac{f(x)}{\phi(x)}\,\frac{dx}{\sqrt{X}}.$$

It can be shown that, when X contains powers of x beyond the second, such integrals cannot be reduced to any of the elementary forms given at the commencement; and, accordingly, they depend on higher transcendental functions. When X is a cubic or a biquadratic, such integrals are reducible to elliptic functions, of which a short account shall be given below. When X is a polynomial of higher degree, the integrals are usually styled hyper-elliptic integrals. They were first treated of in a general manner by Abel.

125. We shall at present consider only the case where X is a quadratic, of the form $a+2bx+cx^2$. The integral

$$\int\frac{f(x)}{\phi(x)}\,\frac{dx}{\sqrt{a+2bx+cx^2}}$$

can be rendered rational in different ways.

(1) First, let the roots of $a+2bx+cx^2=0$ be real, and suppose $a+2bx+cx^2=c(x-\alpha)(x-\beta)$.

If c be positive, we assume $x-\alpha=(x-\beta)z^2$, or $x=\dfrac{\alpha-\beta z^2}{1-z^2}$; then

$$\sqrt{X}=(\alpha-\beta)\sqrt{c}\,\frac{z}{1-z^2}, \text{ and } dx=\frac{2(\alpha-\beta)zdz}{(1-z^2)^2},$$

$$\therefore\ \frac{dx}{\sqrt{X}}=\frac{2}{\sqrt{c}}\,\frac{dx}{1-z^2}.$$

Hence the transformed expression is a rational function of z.

If c be negative, we make $x=\dfrac{\alpha+\beta z^2}{1+z^2}$, and the transformed expression is rational, in like manner.

When the roots α and β are imaginary this method of transformation introduces imaginary forms into our results. In such cases it is usually more advantageous to adopt a different treatment.

For instance, if we assume

$$\sqrt{a+2bx+cx^2}=z-x\sqrt{c},$$

we get $$a+2bx=z^2-2xz\sqrt{c}.$$

Hence $$x=\frac{z^2-a}{2(b+z\sqrt{c})};$$

and $$\frac{dx}{\sqrt{a+2bx+cx^2}}=\frac{dz}{b+z\sqrt{c}}.$$

This substitution consequently furnishes a rational function in z.

Again, when c is negative the expression becomes rational by the assumption

$$\sqrt{a+2bx+cx^2}=\sqrt{a}+xz.$$

In general, if we substitute $\dfrac{\lambda+2\mu z+\nu z^2}{\lambda'+2\mu' z+\nu' z^2}$ for x, where λ, λ', μ, μ', ν, ν' satisfy the equations $\mu^2-\lambda\nu=a$, $\lambda'\nu+\lambda\nu'-2\mu\mu'=2b$, $\mu'^2-\lambda'\nu'=c$, it can be shown without difficulty that

$$\frac{dx}{\sqrt{a+2bx+cx^2}}=\frac{dz}{\lambda'+2\mu' z+\nu' z^2};$$

and accordingly the function

$$\frac{f(x)}{\phi(x)}\,\frac{dx}{\sqrt{a+2bx+cx^2}}$$

becomes rational by this transformation.

This last is a particular case of the general method adopted by Jacobi (*Fundamenta nova theoriæ functionum ellipticarum*) for the transformation of elliptic integrals.

126. The class of integrals here discussed admits also of another mode of treatment.

Thus it can be shown that, if F(x) is an integer rational function of the degree n, then

$$\int\frac{F(x)dx}{\sqrt{a+2bx+cx^2}}=\alpha\int\frac{dx}{\sqrt{a+2bx+cx^2}}$$
$$+\phi(x)\sqrt{a+2bx+cx^2},$$

in which α is a constant, and $\phi(x)$ is at most of the degree $n-1$ in x. For, if we differentiate the expression

$$x^m\sqrt{a+2bx+cx^2}$$

with respect to x, we readily obtain, after the integration of both sides, and the substitution of X for $a+2bx+cx^2$,

$$x^m\sqrt{X}=(m+1)c\int\frac{x^{m+1}dx}{\sqrt{X}}$$
$$+(2m+1)b\int\frac{x^m dx}{\sqrt{X}}+ma\int\frac{x^{m-1}dx}{\sqrt{X}}.$$

Hence, making $m=0, 1, 2, 3 \ldots$ in succession, it is easily seen that $\displaystyle\int\frac{x^n dx}{\sqrt{X}}$ is expressible in terms of $\displaystyle\int\frac{dx}{\sqrt{X}}$ and of an algebraic expression of the form $\phi(x)\sqrt{X}$, where $\phi(x)$ is of the degree $n-1$ at highest.

Again, by the method of partial fractions the integral

$$\int\frac{f(x)}{\phi(x)}\,\frac{dx}{\sqrt{a+2bx+cx^2}}$$

reduces to terms such as the preceding, along with terms of the form

$$\int\frac{dx}{(x-\alpha)^n\sqrt{a+2bx+cx^2}}.$$

If in this latter we substitute $\dfrac{1}{z}$ for $x-\alpha$, it reduces to the form

$$\int\frac{z^{n-1}dz}{\sqrt{A+2Bz+Cz^2}},$$

in which $A=c$, $B=-b-c\alpha$, $C=a+2b\alpha+c\alpha^2$.

127. Integrals of the form here discussed may also be treated by the method of indeterminate coefficients. Thus, writing X for $a+2bx+cx^2$, and differentiating the equation at the commencement of § 126, we get

$$\frac{F(x)}{\sqrt{X}}=\frac{\alpha}{\sqrt{X}}+\phi'(x)\sqrt{X}+\frac{\phi(x)(b+cx)}{\sqrt{X}},$$

or $$F(x)=\alpha+\phi'(x)(a+2bx+cx^2)+\phi(x)(b+cx).$$

Hence, by equating coefficients of like powers of x, the value of α and of the coefficients in $\phi(x)$ can be determined.

For example, let it be proposed to find

$$\int\frac{x^3dx}{\sqrt{a+2bx+cx^2}}.$$

Writing $\lambda+2\mu x+\nu x^2$ for $\phi(x)$, we get

$$x^3=\alpha+2(a+2bx+cx^2)(\mu+\nu x)+(\lambda+2\mu x+\nu x^2)(b+cx),$$

from which we deduce

$$\nu=\frac{1}{3c},\ \mu=-\frac{5b}{12c^2},\ \lambda=\frac{5b^2}{2c^3}-\frac{2a}{3c^2},\ \alpha=\frac{b}{2c^3}(3ac-5b^2).$$

128. Again, if F denote a rational function, the integral

$$\int F(x, \sqrt{ax+b}, \sqrt{a'x+b'})dx$$

is reducible to the preceding type, by making $\sqrt{ax+b}=y$. For this gives

$$dx=\frac{2ydy}{a},\quad \sqrt{a'x+b'}=\sqrt{\frac{a'y^2}{a}+\frac{ab'-a'b}{a}};$$

and the proposed becomes of the form

$$\int f(y, \sqrt{Y})dy,$$

in which Y is of the second degree in y.

129. Having given a sketch of the various methods of reduction of integrals to the forms usually regarded as elementary, we proceed to introduce *further transcendental integrals* by considering the integral $\displaystyle\int e^{nx}\frac{f(x)}{\phi(x)}dx$, in which $f(x)$ and $\phi(x)$ are rational algebraic functions of x.

By the method of partial fractions we may write

$$\frac{f(x)}{\phi(x)}=F(x)+\Sigma\frac{\alpha}{x-a}+\Sigma\frac{\alpha_1}{(x-a)^2}+\ldots+\Sigma\frac{\alpha_n}{(x-a)^{+1}},$$

or, making a slight change in the constants,

$$\frac{f(x)}{\phi(x)}=F(x)+\Sigma A(x-a)^{-1}+\Sigma A_1\frac{d}{dx}(x-a)^{-1}$$

$$+ \ldots + \Sigma A_n \left(\frac{d}{dx}\right)^n (x-a)^{\ 1}$$

$$= F(x) + \Sigma(A + A_1 D + A_2 D^2 + \ldots + A_n D^n)(x-a)^{-1}$$

where D stands for the symbol $\frac{d}{dx}$.

The method of integrating $F(x)e^{nx}dx$ has been already considered (§ 116). The integral of the remainder depends on that of the expression

$$e^{nx}dx(A + A_1 D + A_2 D^2 \ldots + A_n D^n)(x-a)^{-1}.$$

If the symbolic expression $A + A_1 D + A_2 D^2 \ldots + A_n D^n$ be represented by $f(D)$, this integral, in symbolic notation, is represented by

$$D^{-1}e^{nx}f(D)(x-a)^{-1},$$

or, by § 89,

$$D^{-1}f(D-n)\frac{e^{nx}}{x-a}.$$

Again if $f(-n)$, or $A - A_1 n + A_2 n^2 - \ldots \pm A_n n^n$, be represented by N, we have

$$f(D-n) = N - \frac{dN}{dn}D + \frac{d^2N}{dn^2}D^2 - \ldots + A_n D^n.$$

Hence, observing that N, $\frac{dN}{dn}$, $\frac{d^2N}{dn^2}$ . . . are indepenent of x, we have

$$D^{-1}e^{nx}f(D)\frac{1}{x-a} = D^{-1}\left\{N - \frac{dN}{dn}D + \ldots + A_n D^n\right\}\frac{e^{nx}}{x-a}$$

$$= N\int\frac{e^{nx}dx}{x-a} - \frac{dN}{dn}\frac{e^{nx}}{x-a} + \frac{d^2N}{dn^2}\frac{d}{dx}\left(\frac{e^{nx}}{x-a}\right) - \ldots$$

$$+ A_n\left(\frac{d}{dx}\right)^{n-1}\left(\frac{e^{nx}}{x-a}\right).$$

Consequently, the class of integrals here considered depends ultimately on the integral

$$\int\frac{e^{nx}dx}{x-a}.$$

If we make $x - a = \log z$, this integral reduces to the form (§ 115, Ex. 4)

$$\int\frac{dz}{\log z}.$$

It is impossible to represent this latter integral in a finite form, in terms of z. It is accordingly regarded as a function *sui generis*, and is usually styled the *logarithmic integral*, and sometimes Soldner's integral. Its expression in the form of a series will be deduced in a subsequent section.

130. Next, if we replace n by in, where i stands for $\sqrt{-1}$,

$$e^{nx}\frac{f(x)}{\phi(x)} \text{ becomes } (\cos nx + i\sin nx)\frac{f(x)}{\phi(x)},$$

and by an analogous treatment it can be proved that integrals of the forms

$$\int\cos nx\frac{f(x)}{\phi(x)}dx \text{ and } \int\sin nx\frac{f(x)}{\phi(x)}dx$$

depend on the forms

$$\int\frac{\cos z\, dz}{z} \text{ and } \int\frac{\sin z\, dz}{z}.$$

Finally, denoting by $F(\sin x, \cos x)$ an integer polynomial in $\sin x$ and $\cos x$, it can be shown that the integral

$$\int\frac{f(x)}{\phi(x)}F(\sin x, \cos x)dx$$

can be reduced to the same fundamental forms. For the polynomial $F(\sin x, \cos x)$ can be transformed into a linear function of sines and cosines of multiples of x. Again, decomposing $\frac{f(x)}{\phi(x)}$ by the method of partial fractions, the integral in question can be made to depend on integrals of the form

$$\int\frac{\sin mx\, dx}{(x-a)^{n+1}} \text{ and } \int\frac{\cos mx\, dx}{(x-a)^{n+1}},$$

and consequently on

$$\int dx\sin mx\left(\frac{d}{dx}\right)^n\frac{1}{(x-a)} \text{ and } \int dx\cos mx\left(\frac{d}{dx}\right)^n\frac{1}{(x-a)}.$$

These integrals, by the method of § 116, depend on

$$\int dx\,\frac{\left(\frac{d}{dx}\right)^n\sin mx}{x-a} \text{ and } \int dx\,\frac{\left(\frac{d}{dx}\right)^n\cos mx,}{x-a}$$

and, consequently, on the forms

$$\int\frac{\sin z\, dz}{z} \text{ and } \int\frac{\cos z\, dz}{z}.$$

131. These latter integrals also are now regarded as primary functions in analysis, and are incapable of representation in terms of z except by infinite series.

These functions have been largely treated of by mathematicians, more especially by Schlömilch (*Crelle*, vol. xxxiii.), by whom they were styled the sine-integral and the cosine-integral. Also, introducing a slight modification, the logarithmic integral can be written in the form

$$\int\frac{e^{-z}dz}{z}.$$

In this latter shape it is called the exponential integral. Hence, adopting Schlömilch's notation, we write

$$\text{Si } x = \int_0^x\frac{\sin z}{z}dz = \int_0^1\frac{\sin(ux)}{u}du,$$

$$\text{Ci } x = \int_\infty^x\frac{\cos z}{z}dz = \int_\infty^1\frac{\cos(ux)}{u}du,$$

$$\text{Ei } x = \int_\infty^{-x}\frac{e^{-z}}{z}dz = \int_\infty^{-1}\frac{e^{-ux}}{u}du.$$

Again, if $\text{Li } x = \int_0^x\frac{dz}{\log z}$, we have

$$\text{Li } e^x = \text{Ei } x.$$

An interesting and valuable historical account of these transcendental functions is given by Mr. J. W. L. Glaisher in the *Transactions of the Royal Society*, 1870, of which want of space prevents our giving a fuller account. Mr. Glaisher has also, in the same memoir, given tables of the numerical values of these transcendental functions for a number of different arguments.

It may be added that the logarithmic integral was discussed, and tabulated by Soldner in 1809.

Numerous integrals have been reduced to depend on the foregoing transcendents. For example, in the great tables of Bierens de Haan (*Nouvelles tables d' intégrales défines*, Leyden, 1867) nearly 450 forms are shown to be reducible to one or other of the functions considered in this section.

What has been said here will help to exhibit the way in which the necessity for the introduction of new transcendental functions arises as the calculus is developed, and to show that around each new transcendent whole classes of integrals are grouped.

132. The very limited number of differentials which can be integrated in a finite form by aid of the ordinary functions makes it an interesting and important question to find whether the integral of any proposed differential expression is capable of being represented by such functions or not. This problem appears to have been first discussed in a general manner by Abel. Our limits admit only of a statement of one or two of the general results thus arrived at. The reader will find a tolerably full account of the treatment of the question in Bertrand's *Calcul. Intégral*, pp. 89–110.

Abel's fundamental theorem may be stated as follows: Suppose y to be an algebraic function of the variable x, that is, a function defined by a rational equation $F(x, y) = 0$, which is of the nth degree in y; then, if the integral $\int y dx$ be also an algebraic function of x, it must be of the form

$$\int y dx = P_0 + P_1 y + P_2 y^2 + \text{etc.} + P_{n-1}y^{n-1},$$

in which $P_0, P_1, P_2 \ldots P_{n-1}$ are *rational* functions of x. The functions $P_0, P_1 \ldots$ can be investigated by the method of indeterminate coefficients, which, in the great majority of cases, will show the impossibility of an algebraic integral. In the particular case where $y = \sqrt[m]{X}$, X denoting a rational function of x, it has been shown by Liouville, as a consequence of Abel's theorem, that, if the integral $\int dx\sqrt[m]{X}$ be algebraic, it must be of the form $P_1\sqrt[m]{X}$, in which P_1 is a rational algebraic function of x.

Again, denoting X by $\frac{M}{N}$ and substituting T for $M^{n-1}N$, if the integral

$$\int\frac{M dx}{\sqrt[m]{T}},$$

where M and T are whole polynomials, be expressible algebraically, it is of the form $\frac{\Theta}{\sqrt[m]{T}}$, where Θ is another polynomial.

If the equation

$$\int \frac{\mathrm{M}dx}{\sqrt[m]{\mathrm{T}}} = \frac{\Theta}{\sqrt[m]{\mathrm{T}}}$$

be differentiated, we see that the highest degree of x in Θ must be one greater than that in M. Hence, by the method of indeterminate coefficients the integral, if it is algebraic, can be found; or else it can be shown to be impossible under such a form.

Again, if $t, u, v, \ldots$ be algebraic functions of x, the differential of

$$t + \mathrm{A} \log u + \mathrm{B} \log v + \text{etc.},$$

where A, B, C are constants, is evidently algebraic. The converse theorem was investigated by Abel, viz., when y is algebraic, to find when $\int y dx$ can be expressed by algebraic and logarithmic functions. He showed that if

$$\int y dx = t + \mathrm{A} \log u + \mathrm{B} \log v + \mathrm{C} \log w + \text{etc.},$$

then the functions $t, u, v, \ldots$ are capable of being expressed as integer functions of y.

Abel's theorem was extended by Liouville, who started from supposing

$$\int y dx = \mathrm{F}(x, e^u, e^v, \log w, \ldots),$$

where u, v, w, etc., are algebraic functions of x. He proved that when y is algebraic, the expression for its integral cannot contain an exponential, such as e^u. Also that a logarithmic function, such as $\log w$, cannot enter into the integral except in a linear form with a constant coefficient.

In particular, it is shown by Abel that whenever $\int \frac{\mathrm{P}dx}{\sqrt{\mathrm{R}}}$ is expressible explicitly, it must be of the form

$$\int \frac{\mathrm{P}dx}{\sqrt{\mathrm{R}}} = \frac{\Theta}{\sqrt{\mathrm{R}}} + \mathrm{A} \log \frac{\alpha + \beta\sqrt{\mathrm{R}}}{\alpha - \beta\sqrt{\mathrm{R}}} + \mathrm{B} \log \frac{\gamma + \delta\sqrt{\mathrm{R}}}{\gamma - \delta\sqrt{\mathrm{R}}} + \text{etc.},$$

in which P and R are integral polynomial functions of x.

Definite Integrals.

133. The investigations have thus far been chiefly limited to what are styled indefinite integrals. It is plain from § 107 that, whenever the expression $\phi(x)$ remains finite between the limits of integration, its definite integral, taken between those limits, can be determined whenever its indefinite integral is known.

For instance, since

$$\int \frac{dx}{1 + 2x \cos \alpha + x^2} = \frac{1}{\sin \alpha} \tan^{-1}\left(\frac{x + \cos \alpha}{\sin \alpha}\right),$$

we have

$$\int_0^1 \frac{dx}{1 + 2x \cos \alpha + x^2} = \frac{1}{\sin \alpha}\left\{\tan^{-1}\frac{1 + \cos \alpha}{\sin \alpha} - \tan^{-1}\frac{\cos \alpha}{\sin \alpha}\right\}$$
$$= \frac{\alpha}{2 \sin \alpha}.$$

Also (Ex. 8, § 113),

$$\int \frac{dx}{1 + \cos \alpha + x} = \frac{2}{\sin \alpha} \tan^{-1}\left(\tan\frac{\alpha}{2}\tan\frac{x}{2}\right).$$

Accordingly

$$\int_0^\pi \frac{dx}{1 + \cos \alpha \cos x} = \frac{\pi}{\sin \alpha};$$

or

$$\int_0^\pi \frac{dx}{1 + k \cos x} = \frac{\pi}{\sqrt{1 - k^2}}, \text{ when } k < 1.$$

From this we readily get

$$\int_0^{\frac{\pi}{2}} \frac{dx}{a^2 \cos^2 x + b^2 \sin^2 x} = \frac{\pi}{2ab}.$$

134. As definite integrals have frequently to be considered in which we regard one or both of the limits as infinite, it is necessary to determine whether the equation

$$\int_{x_0}^{\mathrm{X}} \mathrm{F}'(x)dx = \mathrm{F}(\mathrm{X}) - \mathrm{F}(x_0)$$

holds for infinite limits.

Suppose when X becomes infinitely great that $\mathrm{F}(x)$ approaches a finite limit, represented by $\mathrm{F}(\infty)$, then

$$\underset{\mathrm{X}=\infty}{\text{lim.}} \int_{x_0}^{\mathrm{X}} \mathrm{F}'(x)dx = \underset{\mathrm{X}=\infty}{\text{lim.}} \left\{\mathrm{F}(\mathrm{X}) - \mathrm{F}(x_0)\right\}$$
$$= \mathrm{F}(\infty) - \mathrm{F}(x_0).$$

Consequently the formula holds in this case.

In like manner if, when x becomes $-\infty$, $\mathrm{F}(x)$ tends to a finite value $\mathrm{F}(-\infty)$, we have

$$\int_{-\infty}^{\mathrm{X}} \mathrm{F}'(x)dx = \mathrm{F}(\mathrm{X}) - \mathrm{F}(-\infty).$$

Also

$$\int_{-\infty}^{+\infty} \mathrm{F}'(x)dx = \mathrm{F}(\infty) - \mathrm{F}(-\infty).$$

Hence, when $\mathrm{F}'(x)$ remains finite between the limits, and $\mathrm{F}(x)$ has *determinate values for both limits*, the equation

$$\int_{x_0}^{\mathrm{X}} \mathrm{F}'(x)dx = \mathrm{F}(x) - \mathrm{F}(x_0)$$

always holds.

For example, in the integral

$$\int \frac{dx}{a^2 + x^2} = \frac{1}{a}\tan^{-1}\left(\frac{x}{a}\right),$$

when $x = \infty$, $\tan^{-1}\left(\frac{x}{a}\right)$ has for its limit $\frac{\pi}{2}$, and when $x = -\infty$, $\tan^{-1}\frac{x}{a}$ has for limit $-\frac{\pi}{2}$; hence

$$\int_0^\infty \frac{dx}{a^2 + x^2} = \frac{\pi}{2a}, \quad \int_{-\infty}^\infty \frac{dx}{a^2 + x^2} = \frac{\pi}{a}$$

Also, from the integrals given in § 114, we get

$$\int_0^\infty e^{-ax} \cos bx \, dx = \frac{a}{a^2 + b^2}, \quad \int_0^\infty e^{-ax} \sin bx \, dx \quad \frac{b}{a^2 + b^2}.$$

Again, in Ex. 4, § 113, we have

$$\mathrm{F}(0) = \frac{b}{(ac - b^2)\sqrt{a}}, \quad \mathrm{F}(\infty) = \frac{\sqrt{c}}{ac - b^2},$$

$$\therefore \int_0^\infty \frac{dx}{(a + 2bx + cx^2)^{\frac{3}{2}}} = \frac{1}{ac^{\frac{1}{2}} + ba^{\frac{1}{2}}}.$$

In like manner, from Ex. 5, § 117, we get

$$\int_0^\infty \frac{dx}{a + 2bx^2 + cx^4} = \frac{\pi}{2\sqrt{ah}}, \text{ where } h = 2(\sqrt{ac} + b).$$

It may be noted that if $\mathrm{F}(x)$ approaches a finite value $\mathrm{F}(\infty)$ as x approaches ∞ the derived function $\mathrm{F}'(x)$ must vanish at the same time.

135. As a further example, let us consider the definite integral

$$\int_{-1}^{+1} \phi(x)\mathrm{X}_n dx,$$

where $\phi(x)$ is an arbitrary polynomial of the degree $n-1$ in x, and X_n is the coefficient of a^n in the expansion of $(1 - 2ax + a^2)^{\frac{1}{2}}$.

It has been shown (§ 56) that

$$\mathrm{X}_n = \frac{1}{2 \,.\, 4 \,.\, 6 \,.\,.\,.\, 2n}\left(\frac{d}{dx}\right)^n (x^2 - 1)^n.$$

Again, by the method of § 116, we have

$$\int dx\phi(x)\left(\frac{d}{dx}\right)^n (x^2 - 1)^n = \Theta + (-1)^n$$
$$\int dx(x^2 - 1)^n \left(\frac{d}{dx}\right)^n \phi(x);$$

moreover, $\left(\frac{d}{dx}\right)^n \phi(x) = 0$ by hypothesis, and when the limits $+1$ and -1 are substituted each term in Θ vanishes separately; hence we have

$$\int_{-1}^{+1} \phi(x)\mathrm{X}_n dx = 0.$$

From this it is readily seen that so long as m and n are unequal we have

$$\int_{-1}^{+1} \mathrm{X}_m \mathrm{X}_n dx = 0.$$

136. There are many integrals which are capable of being determined between certain definite limits without any previous knowledge of the corresponding indefinite integral, and even in cases where the consideration of the indefinite integral would lead to the introduction of a higher transcendental function. Examples of this class will be met with further on.

137. Next, reverting to our original definition (§ 106), we have

$$\int_{x_0}^{\mathrm{X}} f(x)dx$$
$$= \text{lim.}\Big[(x_1 - x_0)f(x_0) + (x_2 - x_1)f(x_1) \,.\,.\, + (\mathrm{X} - x_{n-1})f(x_{n-1})\Big],$$

in which $f(x)$ is supposed to be continuous between the limits x_0 and X. If now A represents the least and B the greatest value of $f(x)$ between these limits, it is plain that

$$(x_1 - x_0)f(x_0) + (x_2 - x_1)f(x_1) + \ldots + (\mathrm{X} - x_{n-1})f(x_{n-1})$$

is greater than $(\mathrm{X} - x_0)\mathrm{A}$, and less than $(\mathrm{X} - x_0)\mathrm{B}$.

Hence

$$\int_{x_0}^{\mathrm{X}} f(x)dx = (\mathrm{X} - x_0)\mathrm{M},$$

where

$$\mathrm{M} > \mathrm{A} \text{ and } < \mathrm{B}.$$

Again, when $f(x)$ is a continuous function, in passing from one limit to the other it varies so as always to lie between the values A and B. Consequently for some value ξ, of x, we must have $f(\xi) = \mathrm{M}$, where ξ lies between x_0 and X, *i.e.*, ξ is of the form $x_0 + \theta(\mathrm{X} - x_0)$, where θ is positive and less than unity. Hence, whenever $f(x)$ is finite and continuous between the limits x_0 and X, we have

$$\int_{x_0}^{\mathrm{X}} f(x)dx = (\mathrm{X} - x_0)f\left\{ x_0 + \theta(\mathrm{X} - x_0) \right\}.$$

In like manner it is shown that

$$\int_{x_0}^{\mathrm{X}} f(x)\phi(x)dx = f\left\{x_0 + \theta(\mathrm{X} - x_0)\right\} \int_{x_0}^{\mathrm{X}} \phi(x)dx$$

provided $f(x)$ and $\phi(x)$ are finite and continuous between the limits x_0 and X, and $\phi(x)$ has always the same sign between these limits.

For example, let $\phi(x) = \frac{1}{x-a}$, and write $f(x)$ instead of $\frac{f(x)}{x-a}$; then

$$\int_{x_0}^{\mathrm{X}} f(x)dx = (\xi - a)f(\xi) \log \frac{\mathrm{X} - a}{x_0 - a},$$

in which we suppose that $\mathrm{X} - a$, $x_0 - a$ have the same sign, and ξ lies between x_0 and X.

In particular, if $a = 0$, we have

$$\int_{x_0}^{\mathrm{X}} f(x)dx = \xi f(\xi) \log \frac{\mathrm{X}}{x_0}.$$

138. *Taylor's Theorem.*—The method of definite integrals furnishes us with a simple demonstration of Taylor's series. For, if in the equation

$$f(\mathrm{X}+h) - f(\mathrm{X}) = \int_{\mathrm{X}}^{\mathrm{X}+h} f'(x)dx$$

we substitute $\mathrm{X} + h - z$ for x, we get

$$f(\mathrm{X}+h) - f(\mathrm{X}) = \int_0^h f'(\mathrm{X} + h - z)dz.$$

Integrating by parts, we have

$$\int f'(\mathrm{X} + h - z)dz = zf'(\mathrm{X} + h - z) + \int zf''(\mathrm{X} + h - z)dz;$$

hence

$$f(\mathrm{X}+h) - f(\mathrm{X}) = hf'(\mathrm{X}) + \int_0^h f''(\mathrm{X} + h - z)zdz.$$

Again,

$$\int_0^h f''(\mathrm{X} + h - z)zdz = \frac{h^2}{1 \,.\, 2} f''(\mathrm{X}) + \int_0^h f'''(\mathrm{X} + h - z)\frac{z^2dz}{1 \,.\, 2},$$

and so on.

Hence we get finally

$$f(\mathrm{X}+h) = f(\mathrm{X}) + \frac{h}{1} f'(\mathrm{X}) + \frac{h^2}{1 \,.\, 2} f''(\mathrm{X}) + \ldots + \frac{h^{n-1}}{|\underline{n-1}} f^{(n-1)}(\mathrm{X}) + \int_0^h f^{(n)}(\mathrm{X} + h - z) \frac{z^{n-1}dz}{|\underline{n-1}}.$$

Accordingly the remainder, R_n, after n terms, in Taylor's series, is represented by the definite integral

$$\frac{1}{|\underline{n-1}} \int_0^h f^{(n)}(\mathrm{X} + h - z)z^{n-1}dz.$$

This value of R_n can be identified with that given in § 46, for by § 137 we have

$$\mathrm{R}_n = \frac{\mathrm{U}}{|\underline{n-1}} \int_0^h z^{n-1}dz = \mathrm{U}\frac{h^n}{|\underline{n}},$$

where U lies between the greatest and least values of $f^{(n)}(\mathrm{X} + h - z)$ between the limits 0 and h for z.

Hence, since any value of z between 0 and h may be represented by $(1 - \theta)h$, where $\theta > 0$ and < 1, we have

$$\mathrm{R}_n = \frac{h^n}{|\underline{n}} f^{(n)}(\mathrm{X} + \theta h).$$

139. Thus far the function $f(x)$ under the sign of integration has been supposed to have a finite value for all values of x between the limits of integration.

Let the indefinite integral of $f(x)dx$ be denoted by $\mathrm{F}(x)$, and suppose $f(x) = \infty$ when $x = a$, where a lies between the limits X and x_0; then, decomposing the integral into two parts, we have

$$\int_{x_0}^{\mathrm{X}} f(x)dx = \underset{x=a}{\mathrm{lim.}} \int_{x_0}^{x} f(x)dx + \underset{x=a}{\mathrm{lim.}} \int_{x}^{\mathrm{X}} f(x)dx$$

$$= \left[\underset{x=a}{\mathrm{lim.}} \mathrm{F}(x) - \mathrm{F}(x_0)\right] + \left[\mathrm{F}(\mathrm{X}) - \underset{x=a}{\mathrm{lim.}} \mathrm{F}(x)\right].$$

Accordingly, whenever $\mathrm{F}(a)$ has a finite and determinate value, we have

$$\int_{x_0}^{\mathrm{X}} f(x)dx = \mathrm{F}(\mathrm{X}) - \mathrm{F}(x_0).$$

This result also holds if $f(x)$ becomes infinite at one of the limits, provided $\mathrm{F}(x)$ is finite and determinate at the same time.

For example, the expression $\frac{1}{\sqrt{(\alpha - x)(x - \beta)}}$ becomes infinite when $x = \alpha$, and also when $x = \beta$; but (Ex. 6, § 113) $\mathrm{F}(\alpha) = \pi$, $\mathrm{F}(\beta) = 0$,

$$\therefore \int_\beta^\alpha \frac{dx}{\sqrt{(\alpha - x)(x - \beta)}} = \pi.$$

140. The complete discussion of the *exceptional cases* in definite integrals is due to Cauchy. We purpose here to give a brief account of his method.

Suppose that the function $f(x)$ becomes infinite for the particular values of x represented by $x_1, x_2, \ldots x_n$, lying between the limits of integration; then we have

$$\int_{x_0}^{\mathrm{X}} f(x)dx = \int_{x_0}^{x_1} f(x)dx + \int_{x_1}^{x_2} f(x)dx \ldots + \int_{x_n}^{\mathrm{X}} f(x)dx$$

$$= \text{lim. of } \left\{ \int_{x_0}^{x_1 - \mu_1\epsilon} f(x)dx + \int_{x_1 + \nu_1\epsilon}^{x_2 - \mu_2\epsilon} f(x)dx + \ldots + \int_{x_n + \nu_n\epsilon}^{\mathrm{X}} f(x)dx \right\},$$

where ϵ denotes an infinitely small quantity, and $\mu_1, \nu_1, \mu_2, \nu_2, \ldots \nu_n$, are *positive* constants, but *arbitrary*.

In addition, if the limits X and x_0 become $+\infty$ and $-\infty$, we write

$$\int_{-\infty}^{+\infty} f(x)dx = \mathrm{lim.} \left\{ \int_{-\frac{1}{\mu\epsilon}}^{x_1 - \mu_1\epsilon} f(x)dx + \int_{x_1 + \nu_1\epsilon}^{x_2 - \mu_2\epsilon} f(x)dx \ldots + \int_{x_n + \nu_n\epsilon}^{\frac{1}{\nu\epsilon}} f(x)dx \right\},$$

in which μ, ν are new positive arbitrary constants.

In all cases, the *general values* of the definite integrals

$$\int_{x_0}^{\mathrm{X}} f(x)dx, \quad \int_{-\infty}^{+\infty} f(x)dx,$$

deduced from the preceding equations, depend on the form of the function $f(x)$, and may be finite and determinate, or infinite, or indeterminate, depending on the values attributed to the arbitrary constants $\mu, \nu, \mu_1, \nu_1, \ldots \mu_n, \nu_n$.

Whenever the integrals become indeterminate, if each of the constants $\mu, \nu, \ldots \mu_n, \nu_n$, be made unity, the corresponding values of

$$\int_{x_0}^{\mathrm{X}} f(x)dx \text{ and } \int_{-\infty}^{+\infty} f(x)dx$$

become

$$\mathrm{lim.}\left[\int_{x_0}^{x_1 - \epsilon} f(x)dx + \int_{x_1 + \epsilon}^{x_2 - \epsilon} f(x)dx \ldots + \int_{x_n + \epsilon}^{\mathrm{X}} f(x)dx\right]$$

and

$$\mathrm{lim.}\left[\int_{-\frac{1}{\epsilon}}^{x_1 - \epsilon} f(x)dx + \int_{x_1 + \epsilon}^{x_2 - \epsilon} f(x)dx \ldots + \int_{x_n + \epsilon}^{\frac{1}{\epsilon}} f(x)dx\right].$$

These are called, by Cauchy, the *principal values* of the definite integrals

$$\int_{x_0}^{\mathrm{X}} f(x)dx \text{ and } \int_{-\infty}^{+\infty} f(x)dx,$$

in the case in question.

Again, the definite integral

$$\int_a^b f(x)dx,$$

if $f(x)$ be finite when $x = a$, is infinitely small if the difference between the limits a and b is an evanescent quantity.

But, if $f(x)$ become infinitely great at the same time, the value of the definite integral may be finite, or even infinite. In the latter cases the integral is called a *singular definite integral.*

For instance, if $f(x_1) = \infty$, the integral

$$\int_{x_1-\epsilon}^{x_1-\mu_1\epsilon} f(x)dx,$$

where ϵ is an infinitesimal, is of this class. Its value may be represented by the method of § 137; for, if f_1 denote the limit of $(x-x_1)f(x_1)$ when $x=x_1$, we have

$$\int_{x_1-\epsilon}^{x_1-\mu_1\epsilon} f(x)dx = f_1 \log \mu_1 .$$

Similarly $$\int_{x_1+\nu_1\epsilon}^{x_1+\epsilon} f(x)dx = f_1 \log \frac{1}{\nu_1} .$$

Again, if the limits a and b each become infinite, while preserving the same sign, we have another class of singular definite integrals, such as

$$\int_{\frac{1}{\epsilon}}^{\frac{1}{\nu\epsilon}} f(x)dx, \int_{-\frac{1}{\mu\epsilon}}^{-\frac{1}{\epsilon}} f(x)dx,$$

in which ϵ is considered evanescent as before.

In this, as in the former case, if $xf(x)$ tend to a limiting value f, when x is infinitely great, we shall have

$$\int_{\frac{1}{\epsilon}}^{\frac{1}{\nu\epsilon}} f(x)dx = f \log\left(\frac{1}{\nu}\right), \quad \int_{-\frac{1}{\mu\epsilon}}^{-\frac{1}{\epsilon}} f(x)dx = f \log \mu .$$

141. We shall illustrate the preceding by a few simple examples commencing with the definite integral

$$\int_{-x_0}^{X} \frac{dx}{x}.$$

Here the function $\frac{1}{x}$ becomes infinite when $x=0$, and we have

$$\int_{-x_0}^{X} \frac{dx}{x} = \int_{-x_0}^{0} \frac{dx}{x} + \int_{0}^{X} \frac{dx}{x}$$
$$= \lim. \left[\int_{-x_0}^{-\mu\epsilon} \frac{dx}{x} + \int_{\nu\epsilon}^{X} \frac{dx}{x}\right],$$

but

$$\int_{\nu\epsilon}^{X} \frac{dx}{x} = \log \frac{X}{\nu\epsilon}, \int_{-x_0}^{-\mu\epsilon} \frac{dx}{x} = \int_{x_0}^{\mu\epsilon} \frac{dz}{z} = \log\left(\frac{\mu\epsilon}{x}\right);$$

$$\therefore \lim. \left[\int_{-x_0}^{-\mu\epsilon} \frac{dx}{x} + \int_{\nu\epsilon}^{X} \frac{dx}{x}\right] = \log \frac{X}{x_0} + \log\left(\frac{\mu}{\nu}\right).$$

Accordingly, the principal value of $\int_{-x_0}^{X} \frac{dx}{x}$ is $\log\left(\frac{X}{x_0}\right)$, and its general value is $\log \frac{X}{x_0} + \log \frac{\mu}{\nu}$. The latter is perfectly arbitrary and indeterminate.

Again, each of the singular definite integrals

$$\int_{\nu\epsilon}^{\epsilon} \frac{dx}{x}, \int_{\frac{1}{\epsilon}}^{\frac{1}{\nu\epsilon}} \frac{dx}{x},$$

is equal to $\log \frac{1}{\nu}$.

Next $$\int_{-x_0}^{X} \frac{dx}{x^2} = \lim. \left[\int_{-x_0}^{-\mu\epsilon} \frac{dx}{x^2} + \int_{\nu\epsilon}^{X} \frac{dx}{x^2}\right].$$

But $$\int_{-x_0}^{-\mu\epsilon} \frac{dx}{x^2} = \frac{1}{\mu\epsilon} - \frac{1}{x_0}, \int_{\nu\epsilon}^{X} \frac{dx}{x^2} = \frac{1}{\nu\epsilon} - \frac{1}{X};$$

$$\therefore \int_{-x_0}^{X} \frac{dx}{x^2} = \lim. \left[\frac{1}{\mu\epsilon} + \frac{1}{\nu\epsilon} - \frac{1}{X} - \frac{1}{x_0}\right].$$

Consequently, the principal value and the general value of the definite integral are both infinite in this case.

In like manner

$$\int_{-x_0}^{X} \frac{dx}{x^2} = \lim. \tfrac{1}{2} \left(\frac{1}{\nu^2\epsilon^2} - \frac{1}{\mu^2\epsilon^2} + \frac{1}{x_0^2} - \frac{1}{X^2}\right).$$

Accordingly, the general value of the integral is infinite, while its principal value is $\frac{1}{2}\left(\frac{1}{x_0^2} - \frac{1}{X^2}\right)$.

Next let us consider the singular definite integral

$$\int_{\frac{1}{\epsilon}}^{\frac{1}{\nu\epsilon}} \frac{(x-a)dx}{(x-a)^2+b^2}.$$

Here $$\int \frac{(x-a)dx}{(x-a)^2+b^2} = \tfrac{1}{2} \log\{(x-a)^2+b^2\}.$$

If we substitute the proposed limits, and afterwards make $\epsilon=0$, we readily find the value of the proposed to be $\log\left(\frac{1}{\nu}\right)$—an indeterminate quantity, as ν is by hypothesis supposed to be arbitrary. Likewise

$$\int_{-\infty}^{+\infty} \frac{(x-a)dx}{(x-a)^2+b^2} = \lim. \int_{-\frac{1}{\mu\epsilon}}^{\frac{1}{\nu\epsilon}} \frac{(x-a)dx}{(x-a)^2+b^2} = \log \frac{\mu}{\nu},$$

when $\epsilon=0$.

Accordingly the general value of

$$\int_{-\infty}^{+\infty} \frac{(x-a)dx}{(x-a^2)+b^2}$$

is perfectly arbitrary, while its principal value is zero.

In like manner, since

$$\int \frac{dx}{(x-a)^2+b^2} = \frac{1}{b} \tan^{-1}\left(\frac{x-a}{b}\right),$$

we find the general and also the principal value of

$$\int_{-\infty}^{+\infty} \frac{dx}{(x-a)^2+b^2} = \frac{\pi}{b}.$$

Again, it readily follows from the last result that, when $ac > b^2$, the value of the definite integral

$$\int_{-\infty}^{\infty} \frac{dx}{a+2bx+cx^2} \text{ is } \frac{\pi}{\sqrt{ac-b^2}}.$$

142. Next let us consider the definite integral

$$u = \int_{0}^{\infty} \frac{\phi(ax)-\phi(bx)}{x} dx.$$

Here $$u = \lim. \int_{\nu\epsilon}^{\frac{1}{\mu\epsilon}} \frac{\phi(ax)-\phi(bx)}{x} dx.$$

But $$\int_{\nu\epsilon}^{\frac{1}{\mu\epsilon}} \frac{\phi(ax)}{x} dx = \int_{a\nu\epsilon}^{\frac{a}{\mu\epsilon}} \frac{\phi(z)dz}{z}, \text{ making } ax=z.$$

Also $$\int_{\nu\epsilon}^{\frac{1}{\mu\epsilon}} \frac{\phi(bx)}{x} dx = \int_{b\nu\epsilon}^{\frac{b}{\mu\epsilon}} \frac{\phi(z)dz}{z},$$

$$\therefore = \lim. \int_{\frac{b}{\mu\epsilon}}^{\frac{a}{\mu\epsilon}} \frac{\phi(z)dz}{z} + \lim. \int_{a\nu\epsilon}^{b\nu\epsilon} \frac{\phi(z)dz}{z},$$

where ϵ is infinitely small.

The limit of the latter integral, as already seen, is $\phi(0) \log\left(\frac{a}{b}\right)$. Also, whenever $\phi(z)$ tends to a definite limiting value $\phi(\infty)$ when z is infinite, we have

$$\int_{\frac{b}{\mu\epsilon}}^{\frac{a}{\mu\epsilon}} \frac{\phi(z)dz}{z} = \phi(\infty) \log\left(\frac{a}{b}\right).$$

$$\therefore \int_{0}^{\infty} \frac{\phi(ax)-\phi(bx)}{x} dx = \{\phi(\infty)-\phi(0)\} \log\left(\frac{a}{b}\right),$$

in this case.

Again, whenever $\int_{\frac{b}{\mu\epsilon}}^{\frac{a}{\mu\epsilon}} \frac{\phi(z)dz}{z}$ is zero, we have

$$\int_{0}^{\infty} \frac{\phi(ax)-(\phi bx)}{x} dx = \phi(0) \log\left(\frac{b}{a}\right).$$

In the latter form this result is called Frullani's theorem, having been communicated by Frullani to Plana in 1821, and subsequently published in *Mem. del. Soc. Ital.*, 1828.

These results, though limited as to their generality, contain many particular integrals under them.

For example, since e^{-ax} becomes 0 when $x=\infty$, and 1 when $x=0$, we have

$$\int_{0}^{\infty} \frac{e^{-ax}-e^{-bx}}{x} dx = \log \frac{b}{a}.$$

Again, when $x=0$, $\tan^{-1}(ax)$ becomes 0; and when $x=\infty$, $\tan^{-1}ax = \frac{\pi}{2}$. Consequently we have

$$\int_{0}^{\infty} \frac{\tan^{-1}ax - \tan^{-1}bx}{x} dx = \frac{\pi}{2} \log \frac{a}{b}.$$

Also, from the periodic character of cos z, it is readily seen that

$$\int_{\frac{b}{\mu\epsilon}}^{\frac{a}{\mu\epsilon}} \frac{\cos z}{z} dz$$

vanishes when $\epsilon = 0$.

Hence $$\int_0^\infty \frac{\cos ax - \cos bx}{x} dx = \log \frac{a}{b}.$$

In like manner we have

$$\int_0^\infty \frac{\log(m + ne^{-ax}) - \log(m + ne^{-bx})}{x} dx$$

$$= \log\left(1 + \frac{m}{n}\right) \log \frac{a}{b}.$$

Frullani's theorem has attracted considerable attention recently, and many remarkable applications, both in single and multiple integrals, have been given by Mr. Elliott, Mr. Leudesdorf, and others, chiefly in the *Proceedings of the London Mathematical Society* 1876, 1877, 1878.

143. The consideration of singular definite integrals furnishes a method for the calculation of the general value of a definite integral when its principal value is known.

Thus, if A be the general value and B the principal value of $\int_{x_0}^{X} f(x)dx$, where $f(x)$ is supposed to become infinite for the values $x_1, x_2 \ldots x_n$ of x, then the difference A − B, from the preceding investigation, will consist of the sum of the singular definite integrals

$$\int_{x_1 - \epsilon}^{x_1 - \mu\epsilon} f(x)dx, \int_{x_1 + \nu_1\epsilon}^{x_1 + \epsilon} f(x)dx, \ldots$$

Consequently if $f_1, f_2 \ldots f_n$, as before, denote the limiting values of

$$(x - x_1)f(x), (x - x_2)f(x), \ldots (x - x_n)f(x),$$

when $x = x_1, x = x_2, \ldots x = x_n$, respectively, we shall have

$$\mathrm{A} - \mathrm{B} = f_1 \log \frac{\mu_1}{\nu_1} + f_2 \log \frac{\mu_2}{\nu_2} + \ldots + f_n \log \frac{\mu_n}{\nu_n}.$$

Accordingly, in order that the definite integral

$$\int_{x_0}^{X} f(x)dx$$

should have a finite and determinate value it is necessary that the quantities $f_1, f_2 \ldots f_n$ should each be evanescent.

When the limits X and x_0 are $+\infty$ and $-\infty$, to the value of A − B here given we must add the term $f \log \frac{\mu}{\nu}$, provided $xf(x)$, as x becomes infinitely great, tends to a definite limiting value f.

144. For example, if $\frac{f(x)}{\mathrm{F}(x)}$ be a rational algebraic function, then the integral $\int_{-\infty}^{+\infty} \frac{f(x)}{\mathrm{F}(x)} dx$ has a finite and determinate value, provided (1) the equation $\mathrm{F}(x) = 0$ has no real roots, and (2) the degree of x in the denominator $\mathrm{F}(x)$ exceeds that of the numerator $f(x)$ by two at least. For the former condition implies that $\frac{f(x)}{\mathrm{F}(x)}$ does not become infinite for any real finite value of x, and it follows from the latter condition that $\frac{xf(x)}{\mathrm{F}(x)}$ becomes evanescent when x becomes infinite.

In order to find the value of $\int_{-\infty}^{+\infty} \frac{f(x)}{\mathrm{F}(x)} dx$ in this case, we suppose

$$\frac{\mathrm{A}(x - a) + \mathrm{B}}{(x - a)^2 + b^2}$$

to represent the partial fraction corresponding to a pair of conjugate roots $a \pm ib$ of the equation $\mathrm{F}(x) = 0$; then, as we have shown that the general and the principal values of the definite integral are the same in this case, we may write

$$\int_{-\infty}^{+\infty} \frac{f(x)}{\mathrm{F}(x)} dx = \lim. \int_{-\frac{1}{\epsilon}}^{+\frac{1}{\epsilon}} \frac{f(x)}{\mathrm{F}(x)} dx$$

$$= \lim. \Sigma \int_{-\frac{1}{\epsilon}}^{+\frac{1}{\epsilon}} \frac{\mathrm{A}(x - a) + \mathrm{B}}{(x - a)^2 + b^2} dx.$$

But we have already seen that

$$\int_{-\frac{1}{\epsilon}}^{+\frac{1}{\epsilon}} \frac{(x - a)dx}{(x - a)^2 + b^2} = 0, \text{ and } \int_{-\frac{1}{\epsilon}}^{+\frac{1}{\epsilon}} \frac{dx}{(x - a)^2 + b^2} = \frac{\pi}{b}.$$

Consequently

$$\int_{-\infty}^{+\infty} \frac{f(x)}{\mathrm{F}(x)} dx = \pi\Sigma \frac{\mathrm{B}}{b}$$

$$= \pi\left(\frac{\mathrm{B}_1}{b_1} + \frac{\mathrm{B}_2}{b_2} + \ldots \frac{\mathrm{B}_n}{b_n}\right),$$

where $\mathrm{B}_1, b_1, \mathrm{B}_2, b_2, \ldots \mathrm{B}_n, b_n$ represent the constants corresponding to the n pairs of imaginary roots in the equation $\mathrm{F}(x) = 0$.

As an example, let us consider the definite integral

$$\int_{-\infty}^{+\infty} \frac{x^{2m}dx}{1 + x^{2n}},$$

where m and n are positive integers, of which n is the greater.

By aid of the theory of equations it can be shown without difficulty that

$$\frac{\mathrm{B}_1}{b_1}, \quad \frac{\mathrm{B}_2}{b_2}, \ldots \frac{\mathrm{B}_n}{b_n}$$

are respectively equal to

$$\frac{\sin\theta}{n}, \quad \frac{\sin 3\theta}{n}, \ldots \frac{\sin(2n-1)\theta}{n},$$

where $$\theta = \frac{2m+1}{2n}\pi.$$

Consequently we have

$$\frac{\mathrm{B}_1}{b_1} + \frac{\mathrm{B}_2}{b_2} \cdots + \frac{\mathrm{B}_n}{b_n} = \frac{1}{n}[\sin\theta + \sin 3\theta + \ldots + \sin(2n-1)\theta]$$

$$= \frac{1}{n \sin \frac{2m+1}{2n}\pi}.$$

Accordingly $$\int_{-\infty}^{+\infty} \frac{x^{2m}dx}{1 + x^{2n}} = \frac{\pi}{n \sin \frac{2m+1}{2n}\pi}.$$

Hence it follows immediately that

$$\int_0^\infty \frac{x^{2m}dx}{1 + x^{2n}} = \frac{\pi}{2n \sin \frac{2m+1}{2n}\pi}.$$

By a corresponding investigation it can be shown that

$$\int_0^\infty \frac{x^{2m}dx}{1 - x^{2n}} = \frac{\pi}{2n} \cot \frac{2m+1}{2n}\pi.$$

These results are readily transformed into

$$\int_0^\infty \frac{x^{a-1}dx}{1+x} = \frac{\pi}{\sin a\pi}, \text{ and } \int_0^\infty \frac{x^{a-1}dx}{1-x} = \pi \cot a\pi,$$

where a is less than unity.

A few simple examples are added.

(1) To show that

$$\int_0^\infty \frac{dx}{(1 - x^2)(\alpha^2 + \beta^2 x^2)} \text{ is equal to } \frac{\pi}{2\alpha(\alpha + \beta)}.$$

(2) If n be less than unity, the equations

$$\int_0^1 \frac{x^n + x^{-n}}{x^2 + 1} dx = \frac{\pi}{2} \sec \frac{n\pi}{2},$$

$$\int_0^1 \frac{x^n - x^{-n}}{x^2 - 1} dx = \frac{\pi}{2} \tan \frac{n\pi}{2},$$

can be readily established.

(3) If $a < \pi$, by a simple transformation it can be shown that

$$\int_0^\infty \frac{e^{ax} + e^{-ax}}{e^{\pi x} + e^{-\pi x}} dx = \tfrac{1}{2} \sec \frac{a}{2},$$

$$\int_0^\infty \frac{e^{ax} - e^{-ax}}{e^{\pi x} - e^{-\pi x}} dx = \tfrac{1}{2} \tan \frac{a}{2}.$$

(4) If $a + b < \pi$, we can prove the equation

$$\int_0^\infty \frac{(e^{ax} + e^{-ax})(e^{bx} + e^{-bx})}{e^{\pi x} + e^{-\pi x}} dx = \frac{2 \cos \frac{a}{2} \cos \frac{b}{2}}{\cos a + \cos b}.$$

(5) To find the value of

$$\int_0^1 \frac{dx}{(1-x^6)^{\frac{1}{6}}}.$$

Assume $$1 - x^6 = \frac{1}{1+y^6},$$

$$\log(1-x^6) = -\log(1+y^6),$$

$$\frac{x^5dx}{1-x^6} = \frac{y^5dy}{1+y^6}\text{; but } y^5 = \frac{x^5}{(1-x^6)^{\frac{5}{6}}}.$$

$$\therefore \int_0^1 \frac{dx}{(1-x^6)^{\frac{1}{6}}} = \int_0^\infty \frac{dy}{1+y^6} = \frac{\pi}{3}.$$

(6) In like manner $\displaystyle\int_0^1 \frac{dx}{(1-x^{2n})^{\frac{1}{2n}}} = \frac{\pi}{2n\sin\frac{\pi}{2n}}$.

145. We now propose to consider some of the general methods of evaluating definite integrals. It is obvious that the value of the definite integral

$$\int_a^b f(x)dx$$

is independent of the variable x, and is a function of the limits a and b, as also of any constant parameters contained in the function $f(x)$. We proceed to show that a definite integral may be differentiated, and also integrated, with respect to any such parameter.

Differentiation under the Sign of Integration.

146. Suppose the function $f(x)$ to contain a constant *parameter* α; *i.e.*, let $f(x) = \phi(x, \alpha)$; then, denoting the definite integral by u, we have

$$u = \int_a^b \phi(x, \alpha)dx.$$

Also, let the limits a and b be independent of α; then, if Δu denote the change in u arising from the change $\Delta\alpha$ in α, we get

$$\Delta u = \int_a^b \{\phi(x, \alpha+\Delta\alpha) - \phi(x, \alpha)\}dx,$$

$$\therefore \frac{\Delta u}{\Delta\alpha} = \int_a^b \frac{\phi(x, \alpha+\Delta\alpha) - \phi(x, \alpha)}{\Delta\alpha}dx.$$

Hence, passing to the limit,

$$\frac{du}{d\alpha} = \int_a^b \frac{d\phi(x, \alpha)}{d\alpha}dx.$$

This principle is called *differentiation under the sign of integration*, and, by aid of it, from any known integral a number of others can in general be determined by differentiation with respect to the constants contained in the integral.

For example, if we differentiate the equation

$$\int_0^\infty e^{-\alpha x}dx = \frac{1}{a},$$

we get $$\int_0^\infty e^{-\alpha x}xdx = \frac{1}{a^2};$$

and, by n successive differentiations,

$$\int_0^\infty e^{-ax}x^n dx = \frac{1 \,.\, 2 \,.\, 3 \,.\, \ldots \,.\, n}{a^{n+1}}.$$

Again, if the equation

$$\int_{-\infty}^{\infty} \frac{dx}{a+2bx+cx^2} = \frac{\pi}{\sqrt{ac-b^2}}$$

be differentiated with respect to a, b, c respectively, we have

$$\int_{-\infty}^{+\infty} \frac{dx}{(a+2bx+cx^2)^2} = \frac{\pi c}{2(ac-b^2)^{\frac{3}{2}}},$$

$$\int_{-\infty}^{+\infty} \frac{xdx}{(a+2bx+cx^2)^2} = \frac{\pi b}{-2(ac-b^2)^{\frac{3}{2}}}.$$

$$\int_{-\infty}^{+\infty} \frac{x^2dx}{(a+2bx+cx^2)^2} = \frac{\pi a}{2(ac-b^2)^{\frac{3}{2}}},$$

Hence $$\int_{-\infty}^{+\infty} \frac{(a'+2b'x+c'x^2)dx}{(a+2bx+cx^2)^2} = \frac{\pi(ac'+a'c-2bb')}{2(ac-b^2)^{\frac{3}{2}}}.$$

A number of other definite integrals can be immediately deduced from these by successive differentiation.

Again, since $$\int_0^\infty \frac{dx}{(a+2bx+cx^2)^{\frac{3}{2}}} = \frac{1}{ha^{\frac{1}{2}}},$$

where $h = \sqrt{ac}+b$, we get, by differentiation,

$$\int_0^\infty \frac{dx}{(a+2bx+cx^2)^{\frac{5}{2}}} = \frac{2h-b}{3h^2a^{\frac{3}{2}}},$$

$$\int_0^\infty \frac{xdx}{(a+2bx+cx^2)^{\frac{5}{2}}} = \frac{1}{3h^2a^{\frac{1}{2}}},$$

$$\int_0^\infty \frac{x^2dx}{(a+2bx+cx^2)^{\frac{5}{2}}} = \frac{1}{3h^2c^{\frac{1}{2}}}.$$

In like manner, if the equation

$$\int_0^{\frac{\pi}{2}} \frac{dx}{\alpha^2\cos^2x + \beta^2\sin^2x} = \frac{\pi}{2\alpha\beta},$$

be differentiated with respect to α and β respectively, we get

$$\int_0^{\frac{\pi}{2}} \frac{\cos^2x dx}{(\alpha^2\cos^2x + \beta^2\sin^2x)^2} = \frac{\pi}{4\alpha^3\beta},$$

$$\int_0^{\frac{\pi}{2}} \frac{\sin^2x dx}{(\alpha^2\cos^2x + \beta^2\sin^2x)^2} = \frac{\pi}{4\alpha\beta^3}.$$

Hence, by addition,

$$\int_0^{\frac{\pi}{2}} \frac{dx}{(\alpha^2\cos^2x + \beta^2\sin^2x)^2} = \frac{\pi(\alpha^2+\beta^2)}{4\alpha^3\beta^3}.$$

From these other definite integrals can be readily found by further differentiation.

147. When the limits are functions of the parameter α, a definite integral admits of differentiation in like manner. For, let Δa, Δb be the changes in the limits corresponding to the increment $\Delta\alpha$ in α, then

$$\Delta u = \int_{a+\Delta a}^{b+\Delta b} \phi(x, \alpha+\Delta\alpha)dx - \int_a^b \phi(x, \alpha)dx$$

$$= \int_a^b \{\phi(x, \alpha+\Delta\alpha) - \phi(x, \alpha)\}dx + \int_b^{b+\Delta b} \phi(x, \alpha+\Delta\alpha)dx$$

$$- \int_a^{a+\Delta a} \phi(x, \alpha+\Delta\alpha)dx.$$

Hence, proceeding to the limit, we get

$$\frac{du}{d\alpha} = \int_a^b \frac{d\phi(x, \alpha)}{d\alpha}dx + \phi(b, \alpha)\frac{db}{d\alpha} - \phi(a, \alpha)\frac{da}{d\alpha}.$$

Integration under the Sign of Integration.

148. We shall next consider the corresponding process called *integration under the sign of integration.*

Suppose $\int_a^b \phi(x, \alpha)dx$ to be represented by u, then

$$\int_a^b \left[\int \phi(x, \alpha)d\alpha\right]dx = \int_a^b \phi(x, \alpha)dx = u,$$

or $$\int_a^b \left[\int \phi(x, \alpha)d\alpha\right]dx = \int u d\alpha,$$

the same limits for α being taken in both integrals.

Suppose α_1 and α_0 to represent the limiting values of α, then the preceding result may be written

$$\int_a^b \left[\int_{\alpha_0}^{\alpha_1} \phi(x, \alpha)d\alpha\right]dx = \int_{\alpha_0}^{\alpha_1}\left[\int_a^b \phi(x, \alpha)dx\right]d\alpha;$$

or, adopting the usual notation,

$$\int_a^b \int_{\alpha_0}^{\alpha_1} \phi(x, \alpha)d\alpha dx = \int_{\alpha_0}^{\alpha_1}\int_a^b \phi(x, a)dx d\alpha.$$

Such expressions are called double integrals, and the result just established is equivalent to the statement that in a double integration, when the limits are independent one of the other, we may effect the integrations in either order without altering the result.

It is easily seen that the preceding statement does not hold if either $\phi(x, \alpha)$, $\dfrac{d\phi(x, \alpha)}{dx}$, or $\dfrac{d\phi(x, \alpha)}{d\alpha}$ become infinite within the assigned limits of integration.

By aid of this principle, from a definite integral involving constant parameters we can often obtain others by the method of integration with respect to one of its parameters.

(1) For example, if the integral

$$\int_0^\infty e^{-ax}\cos bx\,dx=\frac{a}{a^2+b^2}$$

be integrated with respect to a between the limits α and β, we get

$$\int_0^\infty \frac{e^{-\alpha x}-e^{-\beta x}}{x}\cos bx\,dx=\tfrac{1}{2}\log\frac{b^2+\beta^2}{b^2+\alpha^2}.$$

(2) If the same equation be integrated with respect to b between the limits α and 0, we get

$$\int_0^\infty e^{-ax}\frac{\sin \alpha x}{x}\,dx=\tan^{-1}\frac{\alpha}{a}.$$

On making $a=0$ in this it becomes

$$\int_0^\infty \frac{\sin \alpha x}{x}\,dx=\frac{\pi}{2},$$

provided α is positive.

(3) Again, if the definite integral (§ 133)

$$\int_0^\pi \frac{dx}{1+\kappa\cos x}=\frac{\pi}{\sqrt{1-\kappa^2}}$$

be integrated with respect to κ, between the limits 0 and $\sin\alpha$, we get

$$\int_0^\pi \frac{\log(1+\sin\alpha\cos x)}{\cos x}\,dx=\pi\alpha.$$

(4) Next, if the equation

$$\int_0^1 x^n dx=\frac{1}{n+1}$$

be integrated with respect to n between the limits α and β, we get

$$\int_0^1 \frac{x^\beta-x^\alpha}{\log x}dx=\log\frac{1+\beta}{1+\alpha}.$$

(5) To find the value of the integral

$$u=\int_0^\infty e^{-x^2}dx.$$

If zx be substituted for x, we have, since the value of the integral plainly remains unaltered,

$$u=\int_0^\infty ze^{-z^2x^2}dx,$$

$$\therefore\int_0^\infty e^{-z^2(1+x^2)}\,zdx=ue^{-z^2}.$$

Hence, integrating with respect to z between the limits 0 and ∞, we have

$$\int_0^\infty\int_0^\infty e^{-z^2(1+x^2)}zdzdx=u\int_0^\infty e^{-z^2}dz=u^2.$$

Again, $$\int_0^\infty e^{-z^2(1+x^2)}zdz=\tfrac{1}{2}\,\frac{1}{1+x^2},$$

$$\therefore\quad u^2=\tfrac{1}{2}\int_0^\infty\frac{dx}{1+x^2},\quad\text{or } u^2=\frac{\pi}{4}.$$

Consequently $u=\frac{1}{2}\sqrt{\pi}$; *i.e.*, $\int_0^\infty e^{-x^2}dx=\frac{1}{2}\sqrt{\pi}$.

149. In many cases an unknown integral can be reduced to an elementary form by differentiation under the sign of integration.

For example, let

$$u=\int_0^1\frac{\tan^{-1}(ax)}{x\sqrt{1-x^2}}\,dx;$$

then

$$\frac{du}{da}=\int_0^1\frac{dx}{(1+a^2x^2)\sqrt{1-x^2}}=\frac{\pi}{2}\,\frac{1}{\sqrt{1+a^2}},\quad\text{(Ex. 5, § 113).}$$

$$\therefore\quad u=\frac{\pi}{2}\int\frac{da}{\sqrt{1+a^2}}=\frac{\pi}{2}\log\left(a+\sqrt{1+a^2}\right).$$

No constant is added, since $u=0$ when $a=0$.

150. A modification of this method of determining definite integrals is founded on the transformation of a simple integral into a double integral, and the inversion of the order of integration.

(1) For example, when x is positive, we have

$$\frac{1}{x}=\int_0^\infty e^{-xy}dy,$$

$$\therefore\int_0^\infty\frac{\sin ax}{x}\,dx=\int_0^\infty\sin ax\,dx\int_0^\infty e^{-xy}dy$$

$$=\int_0^\infty dy\int_0^\infty e^{-xy}\sin ax\,dx=\int_0^\infty\frac{ady}{a^2+y^2}=\frac{\pi}{2},\quad\text{(§ 148).}$$

(2) Next to find the value of

$$u=\int_0^{\frac{\pi}{2}}\log\left(\frac{a+b\sin\theta}{a-b\sin\theta}\right)\frac{d\theta}{\sin\theta}.$$

Here, from the elementary equation

$$\log\frac{m+n}{m-n}=\int_0^1\frac{2mndx}{m^2-n^2x^2},\ \text{where } m>n,$$

we get $$\log\left(\frac{a+b\sin\theta}{a-b\sin\theta}\right)=\int_0^1\frac{2ab\sin\theta\,dx}{a^2-b^2x^2\sin^2\theta};$$

$$\therefore\ u-2ab\int_0^{\frac{\pi}{2}}\int_0^1\frac{dxd\theta}{a^2-b^2x^2\sin^2\theta}.$$

Hence, inverting the order of integration, we get (§ 133)

$$u=\pi b\int_0^1\frac{dx}{\sqrt{a^2-b^2x^2}}=\pi\sin^{-1}\left(\frac{b}{a}\right).$$

Similarly we get

$$\int_0^{\frac{\pi}{2}}\log\left(\frac{a+b\sin\theta}{a-b\sin\theta}\right)\sin\theta\,d\theta=\pi\frac{a-\sqrt{a^2-b^2}}{b}.$$

Ex. 3. Again, by aid of the equation

$$\tan^{-1}\left(\frac{b}{a}\sin\theta\right)=\int_0^1\frac{ab\sin\theta\,dx}{a^2+b^2x^2\sin^2\theta},$$

it is readily seen that

$$\int_0^{\frac{\pi}{2}}\tan^{-1}\left(\frac{b}{a}\sin\theta\right)\sin\theta\,d\theta=\frac{\pi}{2}\,\frac{\sqrt{a^2+b^2}-a}{b}.$$

151. *Lagrange's Theorem.*—That Lagrange's series (§ 56) can be established by the integral calculus, and its remainder after any number of terms exhibited in the form of a definite integral, was shown by M. Popoff (*Comptes rendus*, 1861). His demonstration has been transformed into a simple shape by M. Zolotareff, in the following manner.

Let $z=x+y\phi(z)$, and suppose the definite integral

$$\int_x^z\left\{y\phi(u)+x-u\right\}^n\mathrm{F}'(u)du$$

represented by s_n, then we get by differentiation

$$\frac{ds_n}{dx}=n\int_x^z\left\{y\phi(u)+x-u\right\}^{x-1}\mathrm{F}'(u)du-y^n\left\{\phi(x)\right\}^n\mathrm{F}'(x)$$

$$=ns_{n-1}-y^n\left\{\phi(x)\right\}^n\mathrm{F}'(x).$$

If we make $n=1$, we have

$$s_0=y\phi(x)\mathrm{F}'(x)+\frac{ds_1}{dx};$$

but $$s_0=\mathrm{F}(z)-\mathrm{F}(x);$$

$$\therefore\quad \mathrm{F}(z)=\mathrm{F}(x)+y\phi(x)\mathrm{F}'(x)+\frac{ds_1}{dx}.$$

In like manner, if $n=2$, we get

$$2s_1=y^2\left\{\phi(x)\right\}^2\mathrm{F}'(x)+\frac{ds_2}{dx},$$

$$\therefore\quad\frac{ds_1}{dx}=\frac{y^2}{1\,.\,2}\frac{d}{dx}\left\{[\phi(x)]^2\mathrm{F}'(x)\right\}+\frac{1}{1\,.\,2}\frac{d^2s_2}{dx^2}.$$

Consequently

$$\mathrm{F}(z)=\mathrm{F}(x)+y\phi(x)\mathrm{F}'(x)+\frac{y^2}{1\,.\,2}\frac{d}{dx}\left[\left\{\phi(x)\right\}^2\mathrm{F}'(x)\right]$$

$$+\frac{1}{1\,.\,2}\frac{d^2s_2}{dx^2}.$$

Again $$s_2=\frac{y^3}{3}\left\{\phi(x)\right\}^3\mathrm{F}'(x)+\frac{1}{3}\frac{ds_3}{dx},$$

$$\therefore\quad\frac{1}{1\,.\,2}\frac{d^2s_2}{dx^2}=\frac{y^3}{1\,.\,2\,.\,3}\left(\frac{d}{dx}\right)^2\left[\left\{\phi(x)\right\}^3\mathrm{F}'(x)\right]$$

$$+\frac{1}{1\,.\,2\,.\,3}\frac{d^3s_3}{dx^3},$$

and so on.

Hence we deduce finally

$$F(z) = F(x) + \frac{y}{1}\phi(x)F'(x) + \frac{y^2}{1.2}\frac{d}{dx}\left[\{\phi(x)\}^2F'(x)\right]$$
$$+ \ldots + \frac{1}{1.2\ldots n}\left(\frac{d}{dx}\right)^n\int_x^z\{y\phi(u) + x - u\}^nF'(u)du.$$

This is Lagrange's series,—in which the remainder after n terms is exhibited in the form

$$\frac{1}{\underline{|n}}\left(\frac{d}{dx}\right)^n\int_x^z\{y\phi(u) + x - u\}^nF'(u)du.$$

Discontinuous Integrals.

152. The integral calculus furnishes many examples of discontinuous functions. For example

$$\int_0^\infty\frac{\sin ax\cos bx}{x}dx = \tfrac{1}{2}\int_0^\infty\frac{\sin(a+b)x}{x}dx$$
$$+ \tfrac{1}{2}\int_0^\infty\frac{\sin(a-b)x}{x}dx.$$

When $a + b$ and $a - b$ are both positive, each of the latter integrals (§ 148) is equal to $\frac{\pi}{2}$. Hence we have—

when $a > b$, $\displaystyle\int_0^\infty\frac{\sin ax\cos bx}{x}dx = \frac{\pi}{2}$,

and when $a < b$, $\displaystyle\int_0^\infty\frac{\sin ax\cos bx}{x}dx = 0$.

If $a = b$, the value of the integral becomes $\frac{\pi}{4}$.

Here we have an example of a function of two variables a and b, changing its value suddenly when b, varying in a continuous manner, becomes equal to or greater than a. This singularity has been ingeniously utilized for the purpose of obtaining the values of certain definite integrals. For example, let

$$u = \int_0^\infty\frac{\sin ax\cos bx}{x}dx;$$

then, since $u = 0$ when a is less than b, and $u = \frac{\pi}{2}$ when $a > b$, we have

$$\int_0^\infty ue^{-a}da = \frac{\pi}{2}\int_b^\infty e^{-a}da = \frac{\pi}{2}e^{-b},$$

or $$\int_0^\infty\int_0^\infty\frac{e^{-a}\sin ax\cos bx}{x}dadx = \frac{\pi}{2}e^{-b}.$$

But $$\int_0^\infty e^{-a}\sin ax\,da = \frac{x}{1+x^2}, \quad (§ 134);$$

$$\therefore \int_0^\infty\frac{\cos bx}{1+x^2}dx = \frac{\pi}{2}e^{-b}.$$

Again, considering b as variable,

$$\int_0^b udb = \int_0^\infty\int_0^b\frac{\sin ax\cos bx}{x}dxdb = \int_0^\infty\frac{\sin ax\sin bx}{x^2}dx.$$

Hence, if $b < a$, we have

$$\int_0^\infty\frac{\sin ax\sin bx}{x^2}dx = \frac{\pi}{2}b;$$

if $b > a$, we have $\displaystyle\int_0^\infty\frac{\sin ax\sin bx}{x^2}dx = \frac{\pi}{2}a$.

Consequently $\displaystyle\int_0^\infty\frac{\sin ax\sin bx}{x^2}dx$ is equal to $\frac{\pi}{2}$ multiplied by the smaller of the numbers a and b.

Again, let us consider the definite integral

$$\int_0^\infty\frac{(a-b\cos x)dx}{a^2-2ab\cos x+b^2}.$$

Here we have

$$\int\frac{(a-b\cos x)dx}{a^2-2ab\cos x+b^2} = \frac{1}{2a}\int\left(1+\frac{a^2-b^2}{a^2-2ab\cos x+b^2}\right)dx$$
$$= \frac{x}{2a} + \frac{a^2-b^2}{2a}\int\frac{dx}{a^2-2ab\cos x+b^2}.$$

Again (Ex. 8, § 113),

$$\int\frac{dx}{a^2-2ab\cos x+b^2} = \frac{2}{a^2-b^2}\tan^{-1}\left(\frac{a+b}{a-b}\tan\frac{x}{2}\right);$$
$$\therefore \frac{a^2-b^2}{2a}\int\frac{dx}{a^2-2ab\cos x+b^2} = \frac{1}{a}\tan^{-1}\left(\frac{a+b}{a-b}\tan\frac{x}{2}\right).$$

Accordingly, if $a^2 > b^2$,

$$\frac{a^2-b^2}{2a}\int_0^\pi\frac{dx}{a^2-2ab\cos x+b^2} = \frac{\pi}{2a}.$$

If $a^2 < b^2$, we have

$$\frac{a^2-b^2}{2a}\int_0^\pi\frac{dx}{a^2-2ab\cos x+b^2} = -\frac{\pi}{2a}.$$

Consequently, when $a^2 - b^2 > 0$,

$$\int_0^\pi\frac{(a-b\cos x)dx}{a^2-2ab\cos x+b^2} = \frac{\pi}{a};$$

when $a^2 - b^2 < 0$,

$$\int_0^\pi\frac{(a-b\cos x)dx}{a^2-2ab\cos x+b^2} = 0;$$

and when $a = b$,

$$\int_0^\pi\frac{a(1-\cos x)dx}{2a^2(1-\cos x)} = \frac{1}{2a}\int_0^\pi dx = \frac{\pi}{2a}.$$

The comparison of these three cases shows that if b be supposed to vary in a continuous manner from a value less than a to a value greater than a, the integral

$$\int_0^\pi\frac{(a-b\cos x)dx}{a^2-2ab\cos x+b^2}$$

will assume for $b = a - h, a, a + h$ the values $\frac{\pi}{a}, \frac{\pi}{2a}, 0$. It is accordingly a discontinuous function.

Eulerian Integrals.

153. The following definite integrals,

$$\int_0^1 x^{m-1}(1-x)^{n-1}dx, \int_0^\infty e^{-x}x^{n-1}dx,$$

were first studied, under a modified form, by Euler, who devoted several memoirs to the investigation of their properties. They were afterwards fully discussed by Legendre, by whom they were styled Eulerian integrals of the first and second species respectively. The latter integral is now regarded as the fundamental one, to which the other is reducible, as shall be presently shown.

In the case where n is an integer we plainly have

$$\int_0^\infty e^{-x}x^{n-1}dx = 1.2.3\ldots n = \underline{|n}.$$

The integral is in all cases a function of n; and, when n is fractional, it is regarded as a distinct transcendental function. It was distinguished by the symbol Γ by Legendre, thus:

$$\Gamma(n) = \int_0^\infty e^{-x}x^{n-1}dx.$$

This is now usually called the *Gamma-Function*, but sometimes, however, the *Factorial Function*, a name suggested by Arbogast, and subsequently adopted by Kramp and others.

Moreover, since (Ex. 6, § 115),

$$\int_0^\infty e^{-x}x^ndx = n\int_0^\infty e^{-x}x^{n-1}dx,$$

we have $\Gamma(n+1) = n\Gamma(n)$.

This may be taken as the fundamental property of gamma-functions, and by aid of it the calculation of all such functions is reduced to the case where the parameter n is comprised between any two consecutive integers. The values of $\Gamma(n)$, or rather of $\log\Gamma(n)$, were tabulated to twelve decimal places by Legendre in his *Traité des fonctions elliptiques*, tome 2, ch. 16, corresponding to values of n increasing by intervals of ·001 between the integers 1 and 2.

It may be remarked that $\Gamma(1) = 1$, $\Gamma(0) = \infty$, $\Gamma(-n) = \infty$, n being an integer. For negative values of n, not being integers, the function has a finite value.

The first Eulerian integral,

$$\int_0^1 x^{m-1}(1-x)^{n-1}dx,$$

is evidently a function of its two parameters, m and n. Following Binet we shall represent the integral by the notation $B(m, n)$.

It is readily seen that

$$\int_0^1 x^{m-1}(1-x)^{n-1}dx = \int_0^1 x^{n-1}(1-x)^{m-1}dx,$$
$$\therefore B(m, n) = B(n, m).$$

Its value, when either m or n is a positive integer, can be immediately found. For, suppose n a positive integer, then (§ 123) we have

$$\int_0^1 x^{m-1}(1-x)^{n-1}dx = \frac{n-1}{m+n-1}\int_0^1 x^{m-1}(1-x)^{n-2}dx.$$

By successive applications we get

$$\int_0^1 x^{m-1}(1-x)^{n-1}dx = \frac{(n-1)(n-2)\,.\,.\,.\,.\,.\,1}{(m+n-1)(m+n-2)\,.\,.\,.\,(m+1)}$$

$$\int_0^1 x^{m-1}dx = \frac{1\,.\,2\,.\,3\,.\,.\,.\,(n-1)}{m(m+1)(m+2)\,.\,.\,.\,(m+n-1)}.$$

The corresponding result when m is an integer is obtained by interchanging the letters m and n.

We now proceed to show that $B(m, n)$ can in all cases be expressed in gamma-functions. For if we substitute zx for x in the equation

$$\Gamma(n) = \int_0^\infty e^{-x}x^{n-1}dx,$$

we get
$$\Gamma(n) = \int_0^\infty e^{-zx}z^nx^{n-1}dx.$$

Hence
$$\Gamma(n)e^{-z}z^{m-1} = \int_0^\infty e^{-z(1+x)}z^{m+n-1}x^{n-1}dx.$$

$$\therefore\quad \Gamma(n)\int_0^\infty e^{-z}z^{m-1}dz$$

$$= \int_0^\infty\int_0^\infty e^{-z(1+x)}z^{m+n-1}x^{n-1}dxdz.$$

Let $z(1+x) = y$, and we get

$$\int_0^\infty e^{-z(1+x)}z^{m+n-1}dz = \frac{1}{(1+x)^{m+n}}$$

$$\int_0^\infty e^{-y}y^{m+n-1}dy = \frac{\Gamma(m+n)}{(1+x)^{m+n}}.$$

Hence
$$\frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)} = \int_0^\infty \frac{x^{n-1}dx}{(1+x)^{m+n}}.$$

Next let
$$u = \frac{x}{1+x},$$

and
$$\int_0^\infty \frac{x^{n-1}}{(1+x)^{m+n}}dx$$

$$= \int_0^1 u^{n-1}(1-u)^{m-1}du = B(m, n).$$

$$\therefore\quad B(m, n) = \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)}.$$

This fundamental relation is due to Euler.

Again, if $m = 1 - n$, we get from the preceding

$$\Gamma(n)\Gamma(1-n) = \int_0^\infty \frac{x^{n-1}}{1+x}dx = \frac{\pi}{\sin n\pi}, \text{ (§ 144).}$$

If $n = \frac{1}{2}$, this becomes $\Gamma(\frac{1}{2}) = \sqrt{\pi}$.

This result agrees with § 148, for, if we write z^2 for x,

$$\Gamma(\tfrac{1}{2}) = \int_0^\infty e^{-x}x^{-\frac{1}{2}}dx = 2\int_0^\infty e^{-z^2}dz.$$

154. Many definite integrals are reducible to gamma-functions, of which a few elementary cases are here given.

(1) To express the definite integral

$$\int_0^{\frac{\pi}{2}} \sin^{n-1}\theta\cos^{m-1}\theta d\theta$$

in gamma-functions.

Let $x = \sin^2\theta$, and the integral transforms into

$$\tfrac{1}{2}\int_0^1 x^{\frac{n}{2}-1}(1-x)^{\frac{m}{2}-1}dx = \tfrac{1}{2}\,\frac{\Gamma\left(\frac{n}{2}\right)\Gamma\left(\frac{m}{2}\right)}{\Gamma\left(\frac{m+n}{2}\right)}.$$

(2) To find the value of

$$\int_0^1 x^m(1-x^n)^r dx.$$

Let $x^n = z$, and the transformed integral is

$$\frac{1}{n}\int_0^1 z^{\frac{m+1}{n}-1}(1-z)^r dz = \frac{1}{n}\,\frac{\Gamma\left(\frac{m+1}{n}\right)\Gamma(r+1)}{\Gamma\left(r+1+\frac{m+1}{n}\right)}.$$

(3) If in the last $r = -\frac{1}{2}$, we get

$$\int_0^1 \frac{x^{m-1}dx}{(1-x)^{\frac{1}{2}}} = \frac{\sqrt{\pi}}{n}\,\frac{\Gamma\left(\frac{m}{n}\right)}{\Gamma\left(\frac{1}{2}+\frac{m}{n}\right)}.$$

(4)
$$u = \int_\beta^\alpha (\alpha - x)^m(x-\beta)^n dx.$$

Let $x = \beta + (\alpha - \beta)z$, and we readily find

$$u = (\alpha-\beta)^{m+n+1}\,\frac{\Gamma(m+1)\Gamma(n+1)}{\Gamma(m+n+2)}.$$

(5) To prove the equations

$$\int_0^\infty e^{-ax}x^{n-1}\cos bx\,dx = \frac{\Gamma(n)}{(a^2+b^2)^{\frac{n}{2}}}\cos n\theta;$$

$$\int_0^\infty e^{-ax}x^{n-1}\sin bx\,dx = \frac{\Gamma(n)}{(a^2+b^2)^{\frac{n}{2}}}\sin n\theta;$$

where $\theta = \tan^{-1}\left(\frac{b}{a}\right)$.

In the equation

$$\int_0^\infty e^{-ax}x^{n-1}dx = \frac{\Gamma(n)}{a^n},$$

let $a - ib$ be substituted for a, and we get

$$\int_0^\infty e^{-ax}(\cos bx + i\sin bx)x^{n-1}dx = \frac{\Gamma(n)}{(a-ib)^n}$$

$$= \frac{\Gamma(n)(a+ib)^n}{(a^2+b^2)^n}.$$

If $b = a\tan\theta$, we have

$$\frac{a}{(a^2+b^2)^{\frac{1}{2}}} = \cos\theta,\quad \frac{b}{(a^2+b^2)^{\frac{1}{2}}} = \sin\theta.$$

$$\therefore\quad \int_0^\infty e^{-ax}(\cos bx + i\sin bx)x^{n-1}dx$$

$$= \frac{\Gamma(n)}{(a^2+b^2)^{\frac{n}{2}}}(\cos n\theta + i\sin n\theta).$$

Hence the proposed equations are obtained by equating the real and imaginary parts respectively.

(6)
$$\int_0^\infty \cos bx\,x^{n-1}dx = \frac{\Gamma(n)}{b^n}\cos\frac{n\pi}{2};$$

$$\int_0^\infty \sin bx\,x^{n-1}dx = \frac{\Gamma(n)}{b^n}\sin\frac{n\pi}{2}.$$

These follow from the preceding by making $n = 0$.

A more rigorous demonstration of this and of the preceding example will be found in Serret's *Calcul intégral*, pp. 194–198.

(7) Find the value of

$$u = \Gamma\left(\frac{1}{n}\right)\Gamma\left(\frac{2}{n}\right)\Gamma\left(\frac{3}{n}\right)\,.\,.\,.\,\Gamma\left(\frac{n-1}{n}\right).$$

Here, since
$$\Gamma\left(\frac{1}{n}\right)\Gamma\left(1-\frac{1}{n}\right) = \frac{\pi}{\sin\frac{\pi}{n}},$$

it is easily seen that

$$u^2 = \frac{\pi^{n-1}}{\sin\frac{\pi}{n}\sin\frac{2\pi}{n}\cdots\sin\frac{(n-1)\pi}{n}}.$$

But it can be shown, by trigonometry, that

$$\sin\frac{\pi}{n}\sin\frac{2\pi}{n}\cdots\sin\frac{(n-1)\pi}{n} = \frac{n}{2^{n-1}};$$

hence
$$\Gamma\left(\frac{1}{n}\right)\Gamma\left(\frac{2}{n}\right)\,.\,.\,.\,\Gamma\frac{n-1}{n} = \frac{(2\pi)^{\frac{n-1}{2}}}{n^{\frac{1}{2}}}.$$

(8) Prove that

$$\int_0^{\frac{\pi}{2}} \cos^n\theta\cos m\theta\,d\theta = \frac{\pi}{2^{n+1}}\,\frac{\Gamma(n+1)}{\Gamma\left(\frac{m+n}{2}+1\right)\Gamma\left(\frac{n+m}{2}-1\right)}.$$

155. We next proceed to show that $\Gamma(n)$ admits of being exhibited as the limit of the product of an infinite number of factors, a form which was adopted by Gauss as the definition of the function.

If in the equation

$$\Gamma(n) = \int_0^\infty e^{-x}x^{n-1}dx$$

we make $e^{-x} = z$, we get

$$\Gamma(n) = \int_0^1\left(\log\frac{1}{z}\right)^{n-1}dz.$$

But (§ 63, Ex. 9) $\log \frac{1}{z}$ is the limit of $\mu\left(1-z^{\frac{1}{\mu}}\right)$ when μ increases beyond limit.

$$\therefore\ \Gamma(n) = \text{lim. } \mu^{n-1}\int_0^1 \left(1-z^{\frac{1}{\mu}}\right)^{n-1}dz$$

$$= \text{lim. } \mu^n\int_0^1 y^{\mu-1}(1-y)^{n-1}dy, \text{ making } z=y^{\mu}.$$

$$\Gamma(n) = \text{lim. } \mu^n \cdot \frac{1\,.\,2\,.\,3\,.\,.\,.\,\mu}{n\,.\,(n+1)\,.\,.\,.\,(n+\mu)}\ (\S\ 123),$$

when μ is increased indefinitely.

As an application of this definition of $\Gamma(n)$ suppose $n+l$ and $n-l$ respectively substituted for n, and we readily obtain

$$\frac{\{\Gamma(n)\}^2}{\Gamma(n-l)\ \Gamma(n+l)} = \left(1-\frac{l^2}{n^2}\right)\left(1-\frac{l^2}{(n+1)^2}\right)\left(1-\frac{l^2}{(n+2)^2}\right)\ .\ .\ .$$

$$= \frac{n}{l\pi}\sin\frac{l\pi}{n},$$

by a well-known trigonometrical relation.

If we make $n=1$, this gives

$$\Gamma(1-l)\Gamma(1+l) = \frac{l\pi}{\sin l\pi};\ \ \therefore\ \Gamma(l)\Gamma(1-l) = \frac{\pi}{\sin l\pi}, \text{ as before.}$$

156. Again, if we make $x=az$, we get

$$\int_0^a x^{m-1}(a-x)^{n-1}dx = a^{m+n-1}\int_0^1 z^{m-1}(1-z)^{n-1}dz$$

$$= a^{m+n-1}\,\frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n)}.$$

This result can be readily represented as a theorem in double integration, as follows.

If the double integral

$$\iint x^{m-1}y^{n-1}dxdy$$

be taken for all *positive* values of x and y subject to the condition $x+y<a$, its value is represented by

$$\frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n+1)}\ a^{m+n}.$$

For, considering x as constant, and integrating with respect to y between the limits 0 and $a-x$, the value of the double integral becomes

$$\frac{1}{n}\int_0^a x^{m-1}(a-x)^n dx, \text{ or } \frac{a^{m+n}}{n}\ \frac{\Gamma(m)\Gamma(n+1)}{\Gamma(m+n+1)},$$

i.e.,
$$a^{m+n}\ \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n+1)}.$$

157. The preceding result, first given by Euler, was generalized by Dirichlet (*Liouville's Journal*, 1839), and extended to a large class of multiple integrals by the following theorem.

Let
$$V = \iiint\ .\ .\ .\ x^{l-1}y^{m-1}z^{n-1}\ .\ .\ .\ dxdydz\ .\ .\ .\ ,$$

in which the variables x, y, z, etc., are always positive, and subject only to the condition

$$x+y+z\ .\ .\ .<1,$$

then
$$V = \frac{\Gamma(l)\Gamma(m)\Gamma(n)\ .\ .\ .}{\Gamma(1+l+m+n\ .\ .\ .\ )}.$$

It will be sufficient here to show that the theorem is true in the case of three variables, x, y, z; *i.e.*, let

$$V = \iiint x^{l-1}y^{m-1}z^{n-1}dxdydz,$$

subject to the foregoing conditions.

Integrating with respect to z, considering x and y constants, we get

$$V = \frac{1}{n}\iint x^{l-1}y^{m-1}(1-x-y)^n dxdy,$$

in which x and y are positive, and subject to the condition $x+y<1$.

If we next integrate with respect to y, between the limits 0 and $1-x$, we have

$$\int_0^{1-x} y^{m-1}(1-x-y)^n dy = (1-x)^{m+n}\ \frac{\Gamma(m)\Gamma(n+1)}{\Gamma(m+n+1)}.$$

Accordingly

$$V = \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n+1)}\int_0^1 x^{l-1}(1-x)^{m+n}dx$$

$$= \frac{\Gamma(m)\Gamma(n)}{\Gamma(m+n+1)}\ \frac{\Gamma(l)\Gamma(m+n+1)}{\Gamma(l+m+n+1)} = \frac{\Gamma(l)\Gamma(m)\Gamma(n)}{\Gamma(l+m+n+1)}.$$

158. The preceding theorem when extended to n variables can be stated somewhat more generally, viz., if

$$V = \iiint\ .\ .\ .\ x^{l-1}y^{m-1}z^{n-1}\ .\ .\ \ dxdydz\ .\ .\ .$$

where x, y, z are always positive and subject to the condition

$$\left(\frac{x}{\alpha}\right)^p + \left(\frac{y}{\beta}\right)^q + \left(\frac{z}{\gamma}\right)^r\ \ .\ .\ .<1,$$

α, β, γ, . . . p, q, r, . . . being positive quantities, then we shall have

$$V = \frac{\alpha^l\beta^m\gamma^n\ .\ .\ .}{pqr\ .\ .\ .}\ \ \frac{\Gamma\left(\frac{l}{p}\right)\Gamma\left(\frac{m}{q}\right)\Gamma\left(\frac{n}{r}\right)\ .\ .\ .}{\Gamma\left(1+\frac{l}{p}+\frac{m}{q}+\frac{n}{r}\ .\ .\ .\right)}.$$

This readily follows from the preceding by making

$$\left(\frac{x}{\alpha}\right)^p = x',\ \left(\frac{y}{\beta}\right)^q = y',\ \left(\frac{z}{\gamma}\right)^r = z',\ .\ .\ .$$

In the case of three variables this theorem contains a large number of results relative to volumes, centres of gravity, moments of inertia, etc.

The remarkable elegance and generality of Dirichlet's theorem immediately attracted notice, and his results were speedily extended by Liouville, Catalan, Leslie Ellis, and other mathematicians of distinction. Of the results thus established we shall content ourselves with giving Liouville's extension of Dirichlet's theorem (*Liouville's Journal*, 1839).

If

$$V = \iiint\ .\ .\ .\ x^{l-1}y^{m-1}z^{n-1}\ .\ .\ .$$
$$f\left\{\left(\frac{x}{\alpha}\right)^p + \left(\frac{y}{\beta}\right)^q\ .\ .\ .\ \right\}dxdydz\ .\ .\ .\ ,$$

where x, y, z are always positive and subject to the condition

$$\left(\frac{x}{\alpha}\right)^p + \left(\frac{y}{\beta}\right)^q + \left(\frac{z}{\gamma}\right)^r\ .\ .\ .<h,$$

α, β, p, q, being always positive, as before, then will

$$V = \frac{\alpha^l\beta^m\gamma^n\ .\ .\ .}{pqr\ .\ .\ .}\ \ \frac{\Gamma\left(\frac{l}{p}\right)\Gamma\left(\frac{m}{q}\right)\ .\ .\ .}{\Gamma\left(\frac{l}{p}+\frac{m}{q}\ .\ .\ .\right)}$$

$$\int_0^h u^{\frac{l}{p}+\frac{m}{q}+\cdots-1}f(u)du\ .$$

This follows without difficulty from the preceding by assuming

$$\left(\frac{x}{\alpha}\right)^p = x',\ \left(\frac{y}{\beta}\right)^q$$

$=y'$, . . . , and then making $x'+y'+z'\ .\ .\ .=u$.

A few examples are added for illustration.

(1) The value of $\iiint dx_1\,dx_2\,dx_3\ .\ .\ .\ dx^n$, where $x_1, x_2\ .\ .\ .\ x^n$ are subject to the condition

$$x_1^2+x_2^2+x_3^2\ .\ .\ .+x_n^2<R^2,$$

is
$$\frac{R^n}{2^n}\ \frac{\pi^{\frac{n}{2}}}{\Gamma\left(1+\frac{n}{2}\right)}.$$

(2) The value of

$$\iiint\ .\ .\ .\ \frac{dx_1dx_2\ .\ .\ .\ dx_n}{\sqrt{1-x_1^2-x_2^2\ .\ .\ .\ -x_n^2}},$$

extended to all positive values of the variables for which the expression is real, is

$$\frac{\pi^{\frac{n+1}{2}}}{2^n\Gamma\left(\frac{n+1}{2}\right)}.$$

(3) The value of

$$\iint x^{k-1}y^{-k}e^{x+y}dxdy$$

extended to all positive values for which $x+y<h$ is

$$\frac{\pi}{\sin k\pi}\ (e^h-1).$$

(4) The value of

$$\iint dxdy\left(\frac{1-x^2-y^2}{1+x^2+y^2}\right)^{\frac{1}{2}}$$

for all real values of the expression, x and y being positive, is

$$\frac{\pi}{4}\left(\frac{\pi}{2}-1\right).$$

(5) The value of

$$\iiint x^{p-1}y^{q-1}z^{r-2}dxdydz$$

extended to all positive values of x, y, z contained within the ellipsoid

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$$

is $$\frac{a^p b^q c^r}{8}\,\frac{\Gamma\left(\frac{p}{2}\right)\Gamma\left(\frac{q}{2}\right)\Gamma\left(\frac{r}{2}\right)}{\Gamma\left(\frac{p+q+r}{2}+1\right)}.$$

(6) Prove that

$$\iiint\ldots\frac{f(a_1x_1+a_2x_2\ldots+a^nx^n)}{\sqrt{1+x_1^2-x_2^2\ldots-x_n^2}}dx_1dx_2\ldots dx_n,$$

when extended to all values subject to the condition

$$x_1^2+x_2^2\ldots+x_n^1<1,$$

is equal to $$\frac{\pi^{\frac{n}{2}}}{\Gamma\left(\frac{n}{2}\right)}\int_{-1}^{1}f(kx)(1-x_2^2)^{\frac{n}{2}-1}dx,$$

where $$k=\sqrt{a_1^2+a_2^2+\ldots+a_n^2}.$$

159. We shall next give a short account of Legendre's formula for the calculation of $\log\Gamma(1+x)$.

Adopting Gauss's definition, substituting $x+1$ for n, and taking the logarithms of both sides of the equation of § 155, we get

$$\log\Gamma(x+1)$$
$$=\lim.\left\{x\log\mu-\log\left(1+\frac{x}{1}\right)-\log\left(1+\frac{x}{2}\right)\ldots\right.$$
$$\left.-\log\left(1+\frac{x}{\mu}\right)\right\}.$$

If now x lie between $+1$ and -1, we may substitute their well-known expansions for $\log\left(1+\frac{1}{x}\right)$, $\log\left(1+\frac{x}{2}\right)\ldots$

Hence, representing the indefinite series

$$\frac{1}{1^n}+\frac{1}{2^n}+\frac{1}{3^n}+\ldots\text{ etc.}$$

by s_n, we shall have

$$\log\Gamma(x+1)=-\gamma x+\tfrac{1}{2}s_2x^2-\tfrac{1}{3}s_3x^3+\tfrac{1}{4}s_4x^4-\ldots\text{ etc.},$$

where γ represents the limit of

$$\tfrac{1}{1}+\tfrac{1}{2}+\tfrac{1}{3}+\ldots+\frac{1}{\mu}-\log\mu$$

when μ is indefinitely increased. This limit, whose importance was first noticed by Euler (*Acta Petropolis*, 1734), is now usually called *Euler's Constant*.

If we change the sign of x in the preceding equation it becomes

$$\log\Gamma(1-x)=\gamma x+\tfrac{1}{2}s_2x^2+\tfrac{1}{3}s_3x^3+\tfrac{1}{4}s_4x^4+\text{etc.}$$

Again $$\frac{\Gamma(1+x)}{\Gamma(1-x)}=\frac{\{\Gamma(1+x)\}^2}{x\Gamma(x)\Gamma(1-x)}=\frac{[\Gamma(1+x)]^2\sin x\pi}{x\pi}.$$

Hence we have

$$\log\Gamma(1+x)=\tfrac{1}{2}\log\frac{x\pi}{\sin x\pi}-(\gamma x+\tfrac{1}{3}s_3x^3+\tfrac{1}{5}s_5x^5+\ldots).$$

Again, by logarithms,

$$\tfrac{1}{2}\log\frac{1+x}{1-x}=x+\tfrac{1}{3}x^3+\tfrac{1}{5}x^5+\text{etc.}$$

Consequently

$$\log\Gamma(1+x)=\tfrac{1}{2}\log\frac{x\pi}{\sin x\pi}-\tfrac{1}{2}\log\left(\frac{1+x}{1-x}\right)$$
$$+(1-\gamma)x-\tfrac{1}{3}(s_3-1)x^3-\tfrac{1}{5}(s_5-1)x^5\ldots$$
$$=\tfrac{1}{2}\log\frac{x\pi}{\sin x\pi}-\tfrac{1}{2}\log\frac{1+x}{1-x}+c_1x-c_3x^3-c_5x^5\ldots,$$

where $c_1=1-\gamma$, $c_3=\frac{1}{3}(s_3-1)$, $c_5=\frac{1}{5}(s_5-1)\ldots$

It is easily seen that the constants c_3, c_5, etc., form a rapidly decreasing series, in which each term can be calculated to any required number of places of decimals. Accordingly, when the value of Euler's constant γ has been determined, a series of values of $\log\Gamma(1+x)$ can be computed from the foregoing equation, and thus tabulated.

Again, since $\Gamma\left(\frac{3}{2}\right)=\frac{\sqrt{\pi}}{2}$, the value of γ may be calculated by making $x=\frac{1}{2}$ in the preceding formula; by this means its value is found to be 0·5772156649 to ten decimal places.

On the Integrals Li x, *Ei* x, *Si* x, *and Ci* x.

160. Having thus arrived at a determination of Euler's constant, we shall return to the consideration of the logarithmic integral and other transcendents introduced into § 131.

Adopting the notation of that article, we have

$$\text{Li}(e^{-x})=\int_\infty^x\frac{e^{-z}}{z}dz=\int_\infty^1\frac{e^{-xu}}{u}du,\text{ writing }xu\text{ for }z;$$

$$\therefore\ \text{Li}(e^{-x})-\text{Li}(e^{-y})=\int_1^\infty\frac{e^{-yu}-e^{-xu}}{u}du$$
$$=\int_0^\infty\frac{e^{-yu}-e^{-xu}}{u}du+\int_0^1\frac{e^{-xu}-e^{-yu}}{u}du.$$

But (§ 142),

$$\int_0^\infty\frac{e^{-yu}-de^{-xu}}{u}du=\log\frac{x}{y};$$
$$\therefore\ \text{Li}(e^{-x})-\text{Li}(e^{-y})=\log x-\log y$$
$$+\int_0^1\frac{1-e^{-yu}}{u}du-\int_0^1\frac{1-e^{-xu}}{u}du.$$

Again $$\int_0^1\frac{1-e^{-yu}}{u}du=\int_0^1\frac{1-(1-u)^y}{u}du$$
$$\int_0^1\frac{e^{-yu}-(1-u)^y}{u}du.$$

But $$\int_0^1\frac{1-(1-u)^y}{u}du=\int_0^1\frac{1-(1-u)^y}{1-(1-u)}du$$
$$=\int_0^1\{1+(1-u)+(1-u)^2+\ldots+(1-u)^{y-1}\}du$$
$$=1+\tfrac{1}{2}+\tfrac{1}{3}+\ldots+\frac{1}{y}.$$

If now we suppose y to increase beyond limit, observing that in that case $\text{Li}e^{-y}=0$, and that $\gamma=$ limit of $1+\frac{1}{2}+\frac{1}{3}+\ldots+\frac{1}{y}-\log y$ when $y=\infty$, we get

$$\text{Li}(e^{-x})=\gamma+\log x-\int_0^1\frac{1-e^{-xu}}{u}du-\lim.$$
$$\int_0^1\frac{e^{-yu}-(1-u)^y}{u}du.$$

We next proceed to show that

$$\int_0^1\frac{e^{-yu}-(1-u)^y}{u}du$$

vanishes when y becomes infinitely great.

To prove this, we observe that, since u lies between 0 and 1,

$$e^{-u}>1-u,\quad\therefore\quad e^{-yu}>(1-u)^y.$$

Also $$e^u>1+u,\ \therefore\ (1-u)e^u>1-u^2,$$

Hence $$1-(1-u)^ye^{yu}<1-(1-u^2)^y<yu^2,$$
$$\therefore\ e^{-yu}-(1-u)^y<yu^2e^{-uy}.$$

Consequently $$\int_0^1\frac{e^{-yu}-(1-u)^y}{u}du<y\int_0^1ue^{-uy}du.$$

Again, $$y\int_0^1ue^{-uy}du=\frac{1}{y}(1-e^{-y})-e^{-y}=0\text{ when }y=\infty.$$

$$\therefore\int_0^1\frac{e^{-yu}-(1-u)^y}{u}du$$

vanishes at the same time.

Hence $$\text{Li}(e^{-x})=\gamma+\log x-\int_0^1\frac{1-e^{-xu}}{u}du.$$

Again

$$\int_0^1\frac{1-e^{-xu}}{u}du=\int_0^1\left(x-\frac{x^2}{1.2}u+\frac{x^3}{1.2.3}u^2-\ldots\right)du$$
$$=x-\tfrac{1}{2}\frac{x^2}{1.2}+\tfrac{1}{3}\frac{x^3}{1.2.3}-\text{etc.}$$

$$\text{Li}(e^{-x})=\gamma+\log x-x+\tfrac{1}{2}\frac{x^2}{1.2}-\tfrac{1}{3}\frac{x^3}{1.2.3}+\text{etc.}$$

Again, $$\text{Li}(e^x)=\int_\infty^{-x}\frac{e^{-z}dz}{z}=-\int_{-x}^\infty\frac{e^{-z}}{z}dz$$
$$=-\lim.\left[\int_{-x}^{-\epsilon}\frac{e^{-z}dz}{z}+\int_\epsilon^\infty\frac{e^{-z}}{z}dz\right],$$

when ϵ vanishes.

But $$\int_\epsilon^\infty=\int_x^\infty=\int_\epsilon^x;$$

$$\therefore\ \text{Li}(e^x)=-\lim.\left[\int_{-x}^{-\epsilon}\frac{e^{-z}dz}{z}+\int_\epsilon^x\frac{e^{-z}dz}{z}\right]$$
$$-\int_x^\infty\frac{e^{-z}}{z}dz=\int_0^x\frac{e^z-e^{-z}}{z}dz-\int_x^\infty\frac{e^{-z}}{z}dz.$$

Let $z = xu$, and this becomes

$$\text{Li}(e^x) = \int_0^1 \frac{e^{xu} - e^{-xu}}{u} du - \int_1^\infty \frac{e^{-xu}}{u} du;$$

$$\therefore \quad \text{Li}(e^x) = \text{Li}(e^{-x}) + \int_0^1 \frac{e^{xu} - e^{-xu}}{u} du;$$

hence

$$\text{Li}(e^x) = \gamma + \log x + x + \tfrac{1}{2}\frac{x^2}{1.2} + \tfrac{1}{3}\frac{x^3}{1.2.3} + \text{etc.}$$

This and the preceding can be represented by the single formula

$$\text{Ei}x = \text{Li}(e^x) = \gamma + \tfrac{1}{4}\log(x^4) + x + \tfrac{1}{2}\frac{x^2}{1.2} + \tfrac{1}{3}\frac{x^3}{1.2.3} + \text{etc.}$$

The expansion for the sine-integral can be readily obtained, for we have by definition

$$\text{Si}x = \int_0^x \frac{\sin z}{z} dz;$$

hence, substituting the ordinary expansion for $\sin z$, and integrating between the limits proposed, we get

$$\text{Si}\, x = x - \tfrac{1}{3}\frac{x^3}{1.2.3} + \tfrac{1}{5}\frac{x^5}{1.2.3.4.5} - \text{etc.}$$

Again, if, in the equation already proved

$$\text{Li}(e^{-x}) = \int_\infty^1 \frac{e^{-xu}}{u} du = \gamma + \tfrac{1}{4}\log(x^4) - x + \tfrac{1}{2}\frac{x^2}{1.2} - \tfrac{1}{3}\frac{x^3}{1.2.3} + \text{etc.}$$

we substitute ix for x, it becomes

$$\int_\infty^1 \frac{e^{-ixu}}{u} du = \gamma + \tfrac{1}{4}\log(x^4) - ix - \tfrac{1}{2}\frac{x^2}{1.2} + \tfrac{1}{3}\frac{ix^3}{1.2.3} + \text{etc.},$$

or
$$\int_\infty^1 \frac{\cos xu - i\sin xu}{u} du = \gamma + \tfrac{1}{4}\log(x^4) - ix - \text{etc.}$$

Hence, equating the real parts on both sides, we get

$$\int_\infty^1 \frac{\cos xu}{u} du = \gamma + \tfrac{1}{4}\log(x^4) - \tfrac{1}{2}\frac{x^2}{1.2} + \tfrac{1}{4}\frac{x^4}{1.2.3.4} - \ldots$$

Consequently

$$\text{Ci}\, x = \gamma + \tfrac{1}{4}\log(x^4) - \tfrac{1}{2}\frac{x^2}{1.2} + \tfrac{1}{4}\frac{x^4}{1.2.3.4} - \text{etc.}$$

The several series here arrived at are readily seen to be convergent for all real values of x, and by aid of them the values of Eix, Six, Cix for different values of the argument x can be tabulated.

Such tables have been constructed by Soldner, Bidone, Bretschneider, Schlömilch, and others. The most recent and complete tables are those of Mr. J. W. L. Glaisher, already referred to (§ 131).

161. The values of some definite integrals can be best determined by transforming them into *infinite series*. This statement will be illustrated by one or two examples.

(1) To find
$$\int_0^1 \frac{\log x}{1-x} dx.$$

Here, when x is less than unity,

$$\frac{\log x}{1-x} = \log x(1 + x + x^2 + \ldots + x^n + \text{etc.});$$

but
$$\int_0^1 x^n \log x\, dx = -\frac{1}{(1+n)^2};$$

consequently

$$\int_0^1 \frac{\log x}{1-x} dx = -(1 + \tfrac{1}{4} + \tfrac{1}{9} + \ldots) = -\frac{\pi^2}{6}.$$

(2) In like manner it can be shown that

$$\int_0^1 \frac{\log x}{1+x} dx = -\frac{\pi^2}{12}, \int_0^1 \frac{\log x}{1-x^2} dx = -\frac{\pi^2}{8}.$$

(3) Again, to find

$$\int_0^1 \frac{x^{a-1} - x^{-a}}{(1+x)\log x} dx.$$

Replacing $\frac{1}{1+x}$ by its development, we get

$$\frac{x^{a-1} - x^{-a}}{1+x} = x^{a-1} - x^{-a} - (x^a - x^{1-a}) + x^{a+1} - x^{2-a}$$
$$- (x^{a+2} - x^{3-a}) \ldots$$

Consequently (Ex. 4, § 148)

$$\int_0^1 \frac{x^{a-1} - x^{-a}}{(1+x)\log x} dx = \log\frac{a}{1-a} - \log\frac{a+1}{2-a} + \log\frac{a+2}{3-a} - \ldots$$

$$= \log\frac{a(a+2)(a+4)\ldots(2-a)(4-a)\ldots}{(1-a)(1+a)(3-a)(3+a)\ldots}$$

$$= \log\frac{a(2^2-a^2)(4^2-a^2)\ldots}{(1^2-a^2)(3^2-a^2)\ldots} = \log\tan\frac{a\pi}{2},$$

by a known formula in trigonometry.

162. Conversely, an infinite series can in many cases be transformed into a definite integral, and thus evaluated.

For example, suppose

$$\text{S} = 1 + \tfrac{1}{3} - \tfrac{1}{5} - \tfrac{1}{7} + \tfrac{1}{9} + \tfrac{1}{11} - \text{etc.}$$

Here, since $\frac{1}{2n+1} = \int_0^1 x^{2n}dx$, we have

$$\text{S} = \int_0^1 dx(1 + x^2 - x^4 - x^6 + \ldots)$$

$$= \int_0^1 \frac{1+x^2}{1+x^4} dx = \frac{\pi}{4}\sqrt{2}.$$

In like manner we get

$$1 - \tfrac{1}{7} + \tfrac{1}{9} - \tfrac{1}{15} + \tfrac{1}{17} - \ldots = \int_0^1 \frac{1-x^6}{1-x^8} dx = \frac{\pi}{4}\,\frac{1+\sqrt{2}}{2}.$$

Again, the series
$$\text{S} = \frac{1}{p(p+1)\ldots(p+n)}$$
$$+ \frac{1}{(p+m)(p+m+1)\ldots(p+m+n)} + \text{etc.}$$

can be represented by a definite integral.

Here

$$\frac{1}{p(p+1)\ldots(p+n)} = \frac{\Gamma(p)}{\Gamma(n+p+1)}$$

$$= \frac{1}{\Gamma(n+1)}\int_0^1 (1-x)^n x^{p-1} dx \ (\S\ 153);$$

$$\therefore \quad \text{S} = \frac{1}{\Gamma(n+1)}\int_0^1 (1-x)^n (x^{p-1} + x^{m+p-1} + \ldots)dx$$

$$= \frac{1}{1.2.3\ldots n}\int_0^1 \frac{(1-x)^n x^{p-1}}{1-x^m} dx.$$

We now proceed to give a few applications of the calculus to geometrical problems.

Areas of Plane Curves.

163. If a plane curve be referred to rectangular axes of co-ordinates, the area between the curve, the axis of X, and two ordinates corresponding to the abscissæ a and b is represented by the definite integral

$$\int_a^b y dx.$$

Hence if $y = \phi(x)$ be the equation of the curve, the area in question is denoted by

$$\int_a^b \phi(x)dx.$$

From this result it follows that every definite integral may be represented by an area. And it is seen at once that all the examples hitherto considered admit of geometrical interpretation.

In the above formula the ordinate is supposed positive for all points of the curve between the limiting abscissæ. The modification when the curve cuts the axis of x can be readily supplied.

Ex. 1. Let the curve be an ellipse, represented by the equation

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1.$$

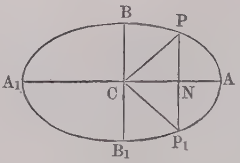

Fig. 7.

Here $y = \frac{b}{a}\sqrt{a^2 - x^2}$; and, if x, y be the co-ordinates of the point P (Fig. 7), the area APN is represented by the integral

$$\frac{b}{a}\int_x^a \sqrt{a^2 - x^2}dx.$$

Let $x = a\cos\phi$, and the integral transforms into

$$ab\int_0^\phi \sin^2\phi d\phi = \frac{ab}{2}(\phi - \sin\phi\cos\phi) = \frac{ab}{2}\cos^{-1}\frac{x}{a} - \frac{xy}{2}.$$

Hence, the area of the elliptic sector APCP₁ is equal to

$$ab\cos^{-1}\frac{x}{a}.$$

If the sectorial area $APCP_1$ be represented by S, the preceding result gives

$$\frac{x}{a}=\cos\frac{S}{ab}, \quad \frac{y}{b}=\sin\frac{S}{ab};$$

or $$\frac{x}{a}=\cos\phi, \quad \frac{y}{b}=\sin\phi, \quad \text{where } \phi=\frac{S}{ab}.$$

Ex. 2. The equation of a hyperbola referred to its axes is

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1.$$

$$\therefore \quad y=\frac{b}{a}\sqrt{x^2-a^2}.$$

Accordingly, if x, y be the co-ordinates of the point P on the curve (fig. 8), the area APN is represented by

$$\frac{b}{a}\int_a^x \sqrt{x^2-a^2}dx=\frac{b}{2a}x\sqrt{x^2-a^2}-\frac{ab}{2}\log\frac{x+\sqrt{x^2-a^2}}{a}$$

$$=\frac{xy}{2}-\frac{ab}{2}\log\left(\frac{x}{a}+\frac{y}{b}\right).$$

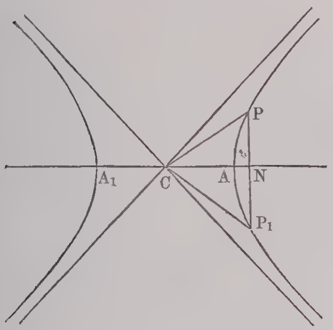

Fig. 8

Consequently the area of the hyperbolic sector ACP is represented by

$$\frac{ab}{2}\log\left(\frac{x}{a}+\frac{y}{b}\right).$$

This relation has given rise to a class of expressions called *hyperbolic functions.* Thus, if S denote the area of the hyperbolic sector $APCP_1$, we have

$$S=ab\log\left(\frac{x}{a}+\frac{y}{b}\right),$$

$$\therefore \quad \frac{x}{a}+\frac{y}{b}=e^{\frac{S}{ab}}.$$

Hence, from the equation

$$\frac{x^2}{a^2}-\frac{y^2}{b^2}=1$$

we get $$\frac{x}{a}-\frac{y}{b}=e^{-\frac{S}{ab}}.$$

Let $\frac{S}{ab}$ be represented by v, and we have

$$\frac{x}{a}=\frac{e^v+e^{-v}}{2}, \quad \frac{y}{b}=\frac{e^v-e^{-v}}{2}.$$

In analogy with the formulæ for the ellipse the expressions

$$\frac{e^v+e^{-v}}{2}, \quad \frac{e^v-e^{-v}}{2}$$

are called the hyperbolic cosine and hyperbolic sine of v respectively, and are usually written $\cosh v$, $\sinh v$; and we have

$$\frac{x}{a}=\cosh v, \quad \frac{y}{b}=\sinh v.$$

Again, for simplicity, the hyperbola may be assumed equilateral, and $a=b=1$; in this case the equations become

$$x=\cosh v, \quad y=\sinh v,$$

where v represents the area of the corresponding hyperbolic sector, represented by $APCP_1$.

Also, by analogy, we write

$$\tanh v=\frac{\sinh v}{\cosh v}=\frac{e^v-e^{-v}}{e^v+e^{-v}}=\frac{e^{2v}-1}{e^{2v}+1}, \text{ etc.}$$

Again, we obviously have

$$\cos x=\cosh ix, \quad i\sin x=\sinh ix.$$

Between hyperbolic functions many relations exist analogous to those between ordinary trigonometrical functions.

For example, it is easily seen that we have

$$\cosh^2x-\sinh^2x=1,$$
$$\cosh(x+y)=\cosh x\cosh y+\sinh x\sinh y,$$
$$\sinh(x+y)=\sinh x\cosh y+\cosh x\sinh y,$$
$$\cosh 3x=4\cosh^3x-3\cosh x,$$
$$\sinh 3x=4\sinh^3x+3\sinh x.$$

Again

$$\frac{d}{dx}\sinh x=\cosh x, \quad \frac{d}{dx}\cosh x=\sinh x,$$

$$\frac{d}{dx}\tanh x=\frac{1}{\cosh^2x}, \quad \frac{d}{dx}\coth x=-\frac{1}{\sinh^2x}.$$

Hence

$$\int\cosh x\,dx=\sinh x, \quad \int\sinh x\,dx=\cosh x,$$

$$\int\frac{dx}{\cosh^2x}=\tanh x, \quad \int\frac{dx}{\sinh^2x.}=-\coth x.$$

The analogy between hyperbolic and trigonometrical functions will also appear as follows. If we make $x=\sec\phi$ in the equation of the equilateral hyperbola $x^2-y^2=1$, we get $y=\tan\phi$. Consequently $\sec\phi=\cosh v$, $\tan\phi=\sinh v$.

Moreover the equation $v=\log(x+y)$, gives

$$\tan\left(\frac{\phi}{2}+\frac{\pi}{4}\right)=e^v.$$

In this case ϕ is called the *hyperbolic amplitude* of v; and, by analogy, we write $\phi=\text{amh } v$. Also when $x=\cosh v$, we have $v=\log(x+\sqrt{x^2-1})$. Again, when $y=\sinh v$, we have $v=\log(y+\sqrt{y^2+1})$.

Moreover, since v is the sector whose corresponding hyperbolic cosine is x, the connection between v and x may be represented by the relation $v=\text{sect}\cosh x$.

Hence we have

$$\text{sect}\cosh x=\log(x+\sqrt{x^2-1}).$$

In like manner we get

$$\text{sect}\sinh x=\log(x+\sqrt{x^2+1}),$$

$$\text{sect}\tanh x=\tfrac{1}{2}\log\frac{1+x}{1-x}.$$

This notation exhibits the analogy between the elementary integrals in a remarkable manner, and even more strikingly when we introduce the Continental notation, arc sin x, instead of $\sin^{-1}x$, etc.

Thus $$\int\frac{dx}{\sqrt{1-x^2}}=\sin^{-1}x=\text{arc}\sin x;$$

$$\int\frac{dx}{\sqrt{1+x^2}}=\log(x+\sqrt{1+x^2})=\text{sect}\sinh x;$$

$$\int\frac{dx}{1+x^2}=\tan^{-1}x=\text{arc}\tan x;$$

$$\int\frac{dx}{1-x^2}=\tfrac{1}{2}\log\frac{1+x}{1-x}=\text{sect}\tanh x.$$

Ex. 3. To find the area included between the cissoid of Diocles and its asymptote.

The equation of this curve is

$$y^2(2a-x)=x^3,$$

and that of its asymptote is $x=2a$.

Hence the area in question is represented by

$$\int_0^{2a}\frac{x^{\frac{3}{2}}dx}{(2a-x)^{\frac{1}{2}}}.$$

Let $x=2a\sin^2\theta$, and the integral becomes

$$8a^2\int_0^{\frac{\pi}{2}}\sin^4\theta d\theta=\tfrac{3}{2}\pi a^2.$$

Ex. 4. To find the whole area of the curve

$$\left(\frac{x}{a}\right)^{\frac{2}{n}}+\left(\frac{y}{b}\right)^{\frac{2}{n}}=1.$$

Let $\frac{x}{a}=\cos^n\theta$; then $\frac{y}{b}=\sin^n\theta$.

Hence the whole area is represented by

$$4nab\int_0^{\frac{\pi}{2}} \sin^{n+1}\theta \cos^{n-1}\theta d\theta.$$

The method of determining this integral has been exhibited in § 122.

164. In the preceding examples the area of any portion of a plane may be conceived as divided into a system of infinitesimal rectangles, $dxdy$, by lines drawn parallel to the axes of co-ordinates. Accordingly any plane area may be represented by $\iint dxdy$, taken between limits determined by the boundary of the area.

Again, as in polar co-ordinates, the plane may be divided by a system of circles having the origin as centre, and also by a system of radii vectores drawn through the origin. In such co-ordinates the element of area bounded by two circles of radii r and $r+dr$ and by the radii vectores corresponding to the angles θ and $\theta+d\theta$ is plainly represented by $rdrd\theta$. Accordingly, any plane area may be represented by

$$\iint rdrd\theta$$

taken between the limits determined by its boundary.

Hence, if the equation of a curve be given in polar coordinates, the sectorial area S bounded by two radii, and the curve is represented by

$$S = \tfrac{1}{2}\int_\alpha^\beta r^2 d\theta,$$

where α and β are the values of θ corresponding to the limiting radii.

(1) For example, in the class of spirals represented by $r = a\theta^m$, we have

$$S = \frac{a^2}{2}\,\frac{\theta^{2m+1}}{2m+1} + \text{const.}$$

If the area be bounded by the prime vector $\theta = 0$, this gives

$$S = \frac{a^2}{2}\,\frac{\theta^{2m+1}}{2m+1}.$$

Thus for the spiral of Archimedes, whose equation is $r = a\theta$,

$$S = \frac{a^2}{6}\theta^3 = \frac{r^3}{6a}.$$

In the spiral, $r^2 = a\theta$, we have

$$S = \frac{a^2\theta^2}{4} = \left(\frac{r^2}{2a}\right)^2.$$

In the reciprocal to this spiral, viz., $r^2\theta = a^2$, we have

$$S = \frac{a^2}{2}\log\theta = a^2\log\left(\frac{a}{r}\right),$$

in which the sector is reckoned from $\theta = 1$.

(2) To find the area of a loop of the curve

$$r^2 = a^2\cos n\theta.$$

Here $r = 0$ when $n\theta = \frac{\pi}{2}$, and $r = a$ when $n\theta = 0$. Consequently the area of a loop is represented by

$$a^2\int_0^{\frac{\pi}{2n}} \cos n\theta\, d\theta,$$

and, accordingly, is $\frac{a^2}{n}$. It is easily seen that when n is a positive integer, the curve consists of n loops; accordingly the entire area of the curve is a^2.

(3) To find the area of the loop of the folium of Descartes, the equation of the curve being $x^3 + y^3 = 3axy$.

Transforming to polar co-ordinates, we get

$$S = \frac{9a^2}{2}\int_0^{\frac{\pi}{2}} \frac{\sin^2\theta\cos^2\theta d\theta}{(\sin^3\theta + \cos^3\theta)^2}.$$

Let $\tan\theta = u$, and this becomes

$$\frac{9a^2}{2}\int_0^\infty \frac{u^2du}{(1+u^3)^2} = \frac{3a^2}{2}.$$

165. If from any point a perpendicular be drawn to any tangent to a curve, the locus of the foot of the perpendicular is called the pedal of the curve with respect to the assumed origin.

If p and ω be the polar co-ordinates of the foot of the perpendicular, the sectorial area of the pedal curve is plainly represented by

$$\tfrac{1}{2}\int p^2 d\omega$$

taken between proper limits.

The following remarkable connection between the pedal areas with respect to the same closed curve, for different internal origins, is due to Steiner. Let A be the area of the pedal with respect to the origin O, A′ the area for origin O′, and p, p' the corresponding perpendiculars, then we have

$$A = \tfrac{1}{2}\int_0^{2\pi} p^2 d\omega, \quad A' = \tfrac{1}{2}\int_0^{2\pi} p'^2 d\omega.$$

If, now, x, y be the co-ordinates of O′ with respect to a pair of rectangular axes drawn through O, we shall have

$$p' = p - x\cos\omega - y\sin\omega;$$

therefore

$$A' - A = \tfrac{1}{2}\int_0^{2\pi}(x\cos\omega + y\sin\omega)^2 d\omega - x\int_0^{2\pi} p\cos\omega\, d\omega - y\int_0^{2\pi} p\sin\omega\, d\omega.$$

But

$$\int_0^{2\pi}\cos^2\omega\, d\omega = \pi, \quad \int_0^{2\pi}\sin^2\omega\, d\omega = \pi,$$

$$\int_0^{2\pi}\sin\omega\cos\omega\, d\omega = 0;$$

consequently $A' - A = \frac{\pi}{2}(x^2 + y^2) - gx - hy$,

where $g = \int_0^{2\pi} p\cos\omega\, d\omega$, $h = \int_0^{2\pi} p\sin\omega\, d\omega$.

Hence we infer that, if O be fixed, *the locus of O′, when the corresponding pedal area A′ is constant, is a circle.*

All the circles obtained by varying the pedal area are concentric. Also the common centre is the point for which the pedal area is a minimum, and the pedal area with respect to any origin exceeds the minimum pedal area by half the area of the circle whose radius is the distance between the pedal origins. Many interesting results may be deduced from this theorem. When the curve is not closed, it is easy to prove, as was shown by Prof. Raabe (*Crelle*, vol. l.), that the locus of the origin for pedals of equal areas is an ellipse. The corresponding theorems for the volumes of the pedals of surfaces were investigated by Dr. Hirst (*Transactions of the Royal Society*, 1863). In addition to other important generalizations, Dr. Hirst has here proved, when the surface is closed, that the locus of the origin for equal pedal volumes is a surface of the second degree.

Another remarkable theorem of Steiner's, on the connection between the areas of pedals and of roulettes, may be stated here. *When a closed curve rolls on a right line, the area between the right line and the roulette generated by any point invariably connected with the rolling curve, in a complete revolution, is double the area of the pedal of the rolling curve, taken with respect to the generating point as origin.* Hence it follows that there is one point in a closed curve for which the entire area of the roulette, described in a complete revolution, is a minimum. Also, the area of the roulette described by any other point exceeds that of the minimum roulette by the area of the circle whose radius is the distance between the points.

Rectification of Curves.

166. The rectification of curves is based on the principle that the length of an arc of any curve is the limit to which the perimeter of an inscribed polygon approaches when each of its sides is conceived to diminish indefinitely.

Hence, if the curve be referred to rectangular axes of coordinates, and if ds denote the element of the arc of the curve at the point (x, y), we shall have

$$ds^2 = dx^2 + dy^2,$$

and accordingly

$$s = \int\left\{1 + \left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}} dx, \text{ or } s = \int\left\{1 + \left(\frac{dx}{dy}\right)^2\right\}^{\frac{1}{2}} dy,$$

taken between the limiting points, *i.e.*, the extremities of the arc.

In like manner if the curve be referred to polar co-ordinates we shall have

$$s = \int\left\{1 + \left(\frac{rd\theta}{dr}\right)^2\right\}^{\frac{1}{2}} dr, \text{ or } s = \int\left\{r^2 + \left(\frac{dr}{d\theta}\right)^{\frac{1}{2}}\right\} d\theta.$$

We shall illustrate these formulæ by a few simple cases.

Ex. 1. In the ordinary parabola $x^2 = 2py$ we have

$$\frac{dy}{dx} = \frac{x}{p};$$

$$\therefore\quad s = \frac{1}{p}\int(x^2 + p^2)^{\frac{1}{2}} dx$$

$$= \frac{(x^2 + p)^{\frac{1}{2}}}{2p} + \frac{p}{2}\log\frac{x + \sqrt{p^2 + x^2}}{p}.$$

Ex. 2. In the more general parabolic curve represented by $x^n = py$ we have

$$\frac{dy}{dx} = \frac{n}{p}\, x^{n-1}\,;$$

$$\therefore\quad s = \int \left(1 + \frac{n^2}{p^2} x^{2n-2}\right)^{\frac{1}{2}} dx\,.$$

This expression is capable of integration in a finite algebraical form (§ 123) for the following values of $2n-2$,

$$1,\ \tfrac{1}{2},\ \tfrac{1}{3},\ \tfrac{1}{4},\ \ldots\ \frac{1}{r},\ \text{etc.}$$

i.e., when n is

$$\tfrac{3}{2},\ \tfrac{5}{4},\ \tfrac{7}{6},\ \ldots\ \frac{2r+1}{2r},\ \text{etc.}$$

167. In illustration of the method of rectification in polar co-ordinates, we commence with the spiral of Archimedes, $r = a\theta$.

Here $$s = \frac{1}{a}\int (r^2 + a^2)^{\frac{1}{2}} dr.$$

This shows that the length of any arc of this spiral is equal to that of a corresponding arc of a parabola.

This relation between the spiral of Archimedes and the parabola was discovered, according to Sir John Leslie, by Gregoire St. Vincent, before the middle of the 17th century (see Leslie's *Geometrical Analysis*, p. 424). That a corresponding relation connected the parabola $y^n = px$ and the spiral $r^{n-1} = \frac{n-1}{n} p\theta$ was established by John Bernoulli (*Acta Erud.*, 1691).

These results were extended by Lardner (*Algebraic Geometry*, p. 355), and in their general form may be stated thus:—

If from the equation to any curve in rectangular co-ordinates another curve in polar co-ordinates be formed, by making dy = dr *and* dx = rdθ, *then the length of any arc of the second curve will be equal to that of the corresponding arc of the first curve. Also the sectorial area of the second curve will be half the area bounded by the corresponding* y *ordinates in the first curve.*

These relations can be immediately established.

As an example, the right line $y = mx$ gives by this transformation the logarithmic spiral $r = e^{m\theta}$. Hence we can always obtain a portion of a right line equal in length to any arc of this spiral,—a result which is obvious otherwise.

Again, from the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \text{ we get } x = \frac{a}{b}\sqrt{b^2 - y^2},$$

$$\therefore\ dx = -\frac{a}{b}\,\frac{y\,dy}{\sqrt{b^2 - y^2}}.$$

Hence the differential equation of the transformed curve is

$$d\theta = -\frac{a}{b}\,\frac{dr}{\sqrt{b^2 - r^2}},$$

from which we get $r = b\cos\frac{b}{a}\theta$

where θ is measured from the line which corresponds to the major axis of the ellipse. Accordingly, the rectification and quadrature of this latter curve is the same as for the ellipse. This can also be shown immediately otherwise.

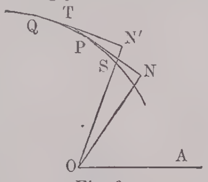

Fig. 9.

168. Whenever the pedal equation of a curve (§ 165) can be found, there is another general formula for its rectification, which may be proved thus.

In fig. 9 let ON be the perpendicular let fall on the tangent at any point P on a curve, and ON′ the perpendicular on the tangent at a consecutive point Q; and suppose ON $= p$, angle AON $= \omega$, and PN $= t$.

Then $\quad \text{PQ} = \Delta s,\quad \text{angle SON} = \Delta\omega,\quad \Delta t = \text{QN}' - \text{PN}.$

Hence $$\frac{ds}{d\omega} = \text{lim.}\frac{\text{PT} + \text{TQ}}{\Delta\omega},\quad \frac{dt}{d\omega} = \text{lim.}\frac{\text{QN}' - \text{PN}}{\Delta\omega}.$$

But $$\text{PT} + \text{TQ} + \text{PN} - \text{QN}' = \text{TN} - \text{TN}';$$

hence $$\frac{ds}{d\omega} - \frac{dt}{d\omega} = \text{lim.}\frac{\text{TN} - \text{TN}'}{\Delta\omega} = \text{lim.}\frac{\text{SN}}{\Delta\omega} = \text{ON} = p.$$

Accordingly, if ω_1 and ω_0 be the values of ω corresponding to the extremities of the arc s, and t_1, t_0 the corresponding values of t, we have

$$s = t_1 - t_0 + \int_{\omega_0}^{\omega_1} p\,d\omega.$$

This theorem is due to Legendre. In its application it is well to observe, that

$$\frac{dp}{d\omega} = \text{lim.}\frac{\text{SN}'}{\Delta\omega} = \text{lim. TN}' = t.$$

For example, in the parabola we have

$$p = \frac{a}{\cos\omega};\quad \therefore\quad \frac{dp}{d\omega} = \frac{a\sin\omega}{\cos^2\omega}.$$

Hence, if s be measured from the vertex of the parabola, we have

$$s = \frac{a\sin\omega}{\cos^2\omega} + a\int_0^{\omega} \frac{d\omega}{\cos\omega} = a\frac{\sin\omega}{\cos^2\omega} + a\log\tan\left(\frac{\pi}{4} + \frac{\omega}{2}\right).$$

Similarly in the ellipse, $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$, we have

$$p = \sqrt{a^2\cos^2\omega + b^2\sin^2\omega}.$$

Accordingly, the rectification of the ellipse depends on the integral

$$\int\sqrt{a^2\cos^2\omega + b^2\sin^2\omega}\,d\omega.$$

Likewise the rectification of the hyperbola depends on the integral

$$\int\sqrt{a^2\cos^2\omega - b^2\sin^2\omega}\,d\omega.$$

Further considerations on the rectification of these curves will be found under the head of elliptic integrals.

169. Steiner's theorem connecting the rectification of pedals and roulettes, analogous to that which connects their areas (§ 165), may be here stated. It is as follows:—

If a curve roll on a right line, the length of the roulette described by any point connected with the rolling curve is equal to the corresponding arc of the pedal of the rolling curve, taken with respect to the describing point as origin.

From this it is easily seen that the length of any arc of a cycloid is equal to that of a corresponding portion of a cardioid, and the length of a trochoid to an arc of a limaçon. Again, if an ellipse be supposed to roll on a right line, the length of the roulette described by either of its foci is equal to the length of the corresponding arc of the auxiliary circle.

Rectification of Curves of Double Curvature.

170. If the points in a curve be not in the same plane, the curve is said to be one of *double curvature.*

Formulæ for the rectification of curves of double curvature are easily obtained. Thus, if the curve be referred to a system of rectangular axes in space, we shall have

$$ds^2 = dx^2 + dy^2 + dz^2.$$

Hence, if x be taken as the independent variable, we have

$$s = \int\left(1 + \frac{dy^2}{dx^2} + \frac{dz^2}{dx^2}\right)^{\frac{1}{2}} dx,$$

and similar formulæ when either y or z is taken as the independent variable.

The equations of the curve are usually written in the form

$$f(x, y) = 0,\ \phi(x, z) = 0;$$

that is, the curve is determined by the intersection of two cylinders. The values of $\frac{dy}{dx}$ and $\frac{dz}{dx}$ deduced from these equations have to be substituted in the foregoing integral.

It is not difficult to determine a relation between the functions f and ϕ in order that the arc of the curve of intersection may admit of easy determination.

The simplest class is where $\left(\frac{dy}{dx}\right)^2 = 2\frac{dz}{dx}$; for in this case

$$s = \int\left(1 + 2\frac{dz}{dx} + \left(\frac{dz}{dx}\right)^2\right)^{\frac{1}{2}} dx$$

$$= \int\left(1 + \frac{dz}{dx}\right) dx = x + z + \text{const.}$$

For example, in the parabolic cylinder

$$x^2 = 2py + \text{const.},$$

we have $$\frac{dy}{dx} = \frac{x}{p}.$$

Accordingly, let $$\frac{dz}{dx}=\tfrac{1}{2}\frac{x^2}{p^2},$$

and we get $$z=\frac{x^3}{6p^2}+\text{const.},$$

hence the length of the curve of intersection of the cylindrical surfaces

$$x^2=2py+c,\ x^3=6p^2z+c'$$

is immediately determined. In general, when $y=f(x)$ is the equation of the first cylinder, and that of the second is represented by the equation

$$z=\tfrac{1}{2}\int\{f'(x)\}^2dx+\text{constant},$$

the arc is determined by the above formula.

171. If we transform to polar co-ordinates by the relations

$$x=r\cos\theta\sin\phi,\ y=r\sin\theta\sin\phi,\ z=r\cos\phi,$$

we get $$ds^2=dr^2+r^2d\phi^2+r^2\sin^2\phi d\theta^2;$$

hence, for the rectification of a curve of double curvature we have

$$s=\int\left(1+r^2\frac{d\phi^2}{dr^2}+r^2\sin^2\phi\frac{d\theta^2}{dr^2}\right)^{\frac{1}{2}}dr;$$

or $$s=\int\left(r^2+\frac{dr^2}{d\phi^2}+r^2\sin^2\phi\frac{d\theta^2}{d\phi^2}\right)^{\frac{1}{2}}d\phi.$$

The latter gives for the length of the arc of a curve on a sphere, of radius a,

$$s=a\int\left(1+\sin^2\phi\frac{d\theta^2}{d\phi^2}\right)^{\frac{1}{2}}d\phi.$$

If ϕ be const. $=\alpha$, the curve lies on a right cone; and we have

$$s=\int\left(1+r^2\sin^2\alpha\frac{d\theta^2}{dr^2}\right)^{\frac{1}{2}}dr.$$

Cubature of Solids.

172. The method usually adopted, in seeking the volume of any solid, consists in supposing it divided by parallel planes into an indefinite number of thin slices. Then in finding the volume we may in the limit consider each slice as an infinitely thin cylindrical plate; and consequently, represent its volume by the product of the area of the corresponding section into the indefinitely small distance between the parallel planes which bound it.

Thus, if the points in the body be referred to a system of rectangular axes of co-ordinates, and the system of parallel planes be perpendicular to the axis of x, then, representing the area of the section at the distance x from the origin by A_x, the volume of the solid will be represented by

$$\int A_xdx$$

taken between proper limits.

Adopting a similar notation, the volume of a solid may be represented by

$$\int A_ydy,\text{ or }\int A_zdz.$$

In the case of a surface of revolution, the sections are drawn perpendicular to the axis of revolution. Thus, if any curve, situated in the plane xy, turn round the axis of x, a plane perpendicular to the axis cuts the surface in a circle. The area of this circle is πy^2; consequently the volume between two sections, correspoding to the abscissæ a and b, is represented by

$$\pi\int_a^b y^2dx.$$

(1) Suppose the ellipse $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$ to revolve round its axis of x, then the entire volume of the generated solid is

$$\pi\int_{-a}^{+a}b^2\left(1-\frac{x^2}{a^2}\right)dx=2\pi b^2\int_0^a\left(1-\frac{x^2}{a^2}\right)dx=\tfrac{4}{3}\pi ab^2.$$

(2) If the parabola $y=ax^n$ revolve round the axis of x, the volume cut off by a plane at the distance X from the origin is

$$\pi\int_0^X a^2x^{2n}dx=\frac{\pi a^2X^{2n+1}}{2n+1}=\pi\frac{XY^2}{2n+1}.$$

(3) To find the volume of the ellipsoid

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1.$$

Here the section at the distance z from the origin is the ellipse

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1-\frac{z^2}{c^2}.$$

The area of this section A_z is

$$\pi\left(1-\frac{z^2}{c^2}\right)ab;$$

accordingly the volume of the ellipsoid is represented by

$$2\pi ab\int_0^c\left(1-\frac{z^2}{c^2}\right)dz=\tfrac{4}{3}\pi abc.$$

(4) To find the volume of the surface generated by the revolution of a cycloid round its base.

It is easily seen that the co-ordinates of any point on a cycloid, of radius a, are capable of being represented by

$$x=a(\phi+\sin\phi),\ y=a(1+\cos\phi).$$

Hence the volume V generated is given by the equation

$$V=2\pi a^3\int_0^\pi(1+\cos\phi)^3d\phi=16\pi a^3\int_0^\pi\cos^6\frac{\phi}{2}\,d\phi=5\pi^2a^3.$$

(5) To find the volume of the portion of the paraboloid

$$\frac{x^2}{l}+\frac{y^2}{m}=2z$$

cut off by a plane drawn perpendicular to the axis of z.

Here, the area of the section at the distance z from the origin is $2\pi z\sqrt{lm}$. Hence if c be the distance of the bounding plane,

$$V=2\pi\sqrt{lm}\int_0^c zdz=\pi c^2\sqrt{lm}.$$

Consequently the volume is half that of the circumscribing cylinder.

173. Again, since any solid can be supposed divided into an indefinite number of elementary parallelepipeds, the volume enclosed within any boundary may be represented by

$$\iiint dxdydz,$$

the limits being determined in each case by the nature of the problem.

For example, cubature of the ellipsoid

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$$

is equivalent to the determination of the triple integral

$$\iiint dxdydz,$$

for all values of x, y, z subject to the relation

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}<1.$$

Here, as in all other cases, we integrate, first, with respect to one of the variables, regarding the others as constant, and determine the limits from the given relation.

Thus, integrating with respect to z, and observing that the limiting values of z are $\pm c\sqrt{1-\frac{x^2}{a^2}-\frac{y^2}{b^2}}$, we get

$$V=2c\iint\sqrt{1-\frac{x^2}{a^2}-\frac{y^2}{b^2}}dxdy,$$

in which x, y are connected by the relation

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}<1.$$

This integral is easily determined by making

$$\frac{y}{b}=\sqrt{1-\frac{x^2}{a^2}}\sin\phi;$$

then $$dy=b\sqrt{1-\frac{x^2}{a^2}}\cos\phi\,d\phi,$$

and $$V=2bc\iint\left(1-\frac{x^2}{a^2}\right)\cos^2\phi\,d\phi,$$

where the limits for ϕ are $\frac{\pi}{2}$ and $-\frac{\pi}{2}$.

But $$\int_{-\frac{\pi}{2}}^{+\frac{\pi}{2}}\cos^2\phi d\phi=\frac{\pi}{2},$$

hence $$V=\pi bc\int_{-a}^{+a}\left(1-\frac{x^2}{a^2}\right)dx=\tfrac{4}{3}\pi abc,\text{ as before.}$$

The geometrical interpretation of each step in the preceding demonstration can be readily supplied by the reader.

It may be observed that, in consequence of the symmetry of the ellipsoid, the preceding integrations might have been limited to positive values of x, y, z,—thus determining the eighth part of the entire volume. A similar remark applies to any symmetrical surface. It will also be observed that the determination of the volume of an ellipsoid is a simple case of the theorem given in § 157.

Similarly the volume included within the surface

$$\left(\frac{x}{a}\right)^{\frac{2}{l}} + \left(\frac{y}{b}\right)^{\frac{2}{m}} + \left(\frac{z}{c}\right)^{\frac{2}{n}} = 1$$

is reducible to the determination of the triple integral

$$\iiint dxdydz$$

extended to all positive values of x, y, z, subject to the condition

$$\left(\frac{x}{a}\right)^{\frac{2}{l}} + \left(\frac{y}{b}\right)^{\frac{2}{m}} + \left(\frac{z}{c}\right)^{\frac{2}{n}} < 1\,.$$

Hence, by § 157, we get

$$\mathrm{V} = lmnabc\ \frac{\Gamma\left(\frac{l}{2}\right)\Gamma\left(\frac{m}{2}\right)\Gamma\left(\frac{n}{2}\right)}{\Gamma\left(1+\frac{l+m+n}{2}\right)}\,.$$

Thus, for instance, the volume enclosed by the surface

$$\left(\frac{x}{a}\right)^{\frac{2}{3}} + \left(\frac{y}{b}\right)^{\frac{2}{3}} + \left(\frac{z}{c}\right)^{\frac{2}{3}} = 1 \text{ is } \frac{4\pi abc}{5\,.\,7}\,.$$

In like manner the volume enclosed within the surface

$$\left(\frac{x}{a}\right)^{\frac{2}{5}} + \left(\frac{y}{b}\right)^{\frac{2}{5}} + \left(\frac{z}{c}\right)^{\frac{2}{5}} = 1 \text{ is } \frac{20\pi abc}{3.7.11.13}\,,$$

and so on.

174. From the preceding it will be apparent that every double integral may, in general, be represented by a volume.

As an example, let us consider the double integral

$$u = \int_0^{2a}\int_0^{\frac{b}{a}\sqrt{2ax-x^2}} f(x\,,\,y)dxdy\,.$$

Here, since $y > 0$ and $< \frac{b}{a}\sqrt{2ax-x^2}$, and the limits of x are 0 and $2a$, it is readily seen that the integral represents half the volume of the solid bounded by the surface $z = f(x, y)$, by the plane of xy, and by the cylinder having as its base the ellipse

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} - \frac{2x}{a} = 1\,.$$

For instance, suppose the bounding surface to be the paraboloid

$$\frac{x^2}{l} + \frac{y^2}{m} = 2z\,,$$

then the volume in question becomes

$$u = \tfrac{1}{2}\int_0^{2a}\int_0^{\frac{b}{a}\sqrt{2ax-x^2}} \left(\frac{x^2}{l} + \frac{y^2}{m}\right)dxdy$$

$$= \frac{b}{2a}\int_0^{2a}\left\{\frac{x_2}{l}(2ax-x^2)^{\frac{1}{2}} + \frac{b^2}{3ma^2}(2ax-x^2)^{\frac{3}{2}}\right\}dx\,.$$

To integrate this, assume $x = 2a\sin^2\theta$, and we get

$$u = \frac{16a^3b}{l}\int_0^{\frac{\pi}{2}}\cos^2\theta\sin^6\theta d\theta + \frac{16ab^3}{3m}\int_0^{\frac{\pi}{2}}\sin^4\theta\cos^4\theta d\theta$$

$$= \frac{\pi ab}{8}\left(\frac{5a^2}{l} + \frac{b^2}{m}\right)\cdot$$

175. Again, the double integral

$$\int_{x_0}^{\mathrm{X}}\int_{y_0}^{\mathrm{Y}} f(x,\,y)dxdy\,,$$

when the limits X, x_0, Y, y_0 are constants, represents the volume bounded by the plane xy, the surface $z = f(x, y)$, and the planes $x = \mathrm{X}$, $x = x_0$, $y = \mathrm{Y}$, $y = y_0$. Also, in the determination of this double integral the order of integration may, in general, be changed (§ 148); and this change in the order produces no alteration in the limits. The latter statement no longer holds when the limits of integration with respect to the first variable are functions of the second.

In this latter case it is of importance to be able to determine in each case what are the new limits when the order of integration is reversed. This can generally be best effected from geometrical considerations; thus, for instance, in the example of the preceding article, we readily find, when the order is reversed, the new limits of x to be $a + a\sqrt{1-\frac{y^2}{b^2}}$ and $a - a\sqrt{1-\frac{y^2}{b^2}}$, and that the subsequent limits for y are 0 and b.

As another example, let us consider the double integral

$$u = \int_0^{a}\int_0^{\frac{b}{a}x} f(x,\,y)dxdy.$$

If we take on the axis of x a portion $\mathrm{OA} = a$ (fig. 10), and on the axis of y, $\mathrm{OB} = b$, and complete the rectangle OACB, it is plain from the equation that the point (x, y) is limited to the triangle OAC.

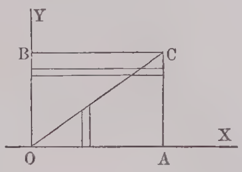

Fig. 10.

Accordingly, if the order of integration be reversed, we must suppose the area, instead of being divided into infinitesimal strips parallel to the axis of y, to be divided into strips parallel to the axis of x. Hence, the limits for x, when y is constant, are a and $\frac{ay}{b}$; and the subsequent limits for y are b and 0.

Consequently,

$$\int_0^{a}\int_0^{\frac{b}{a}x} f(x,\,y)dxdy = \int_0^{b}\int_{\frac{ay}{b}}^{a} f(x,\,y)dxdy.$$

As an exemplification of the advantage of an interchange in the order of integration it will suffice to take the double integral

$$u = \int_0^{a}\int_0^{x}\frac{f'(y)dxdy}{\sqrt{(a-x)(x-y)}}\cdot$$

Here, interchanging the order, we have by the preceding

$$u = \int_0^{a}\int_y^{a}\frac{f'(y)dydx}{\sqrt{(a-x)(x-y)}}\cdot$$

But (§ 139), $\displaystyle\int_y^{a}\frac{dx}{\sqrt{(a-x)(x-y)}} = \pi$,

$$\therefore\ u = \pi\int_0^{a} f'(y)dy = \pi\{f(a) - f(0)\}\cdot$$

It may be observed that in many cases, when the order of integration is reversed, we get two or more double integrals instead of the original integral.

176. It is frequently found necessary to transform a double integral

$$\iint f(x,\,y)dxdy\,,$$

referred to rectangular co-ordinates, to another referred to polar co-ordinates.

In this case, as in § 164, we substitute $rdrd\theta$ instead of $dxdy$, and the integral becomes

$$\iint f(r\cos\theta,\,r\sin\theta)rdrd\theta\,.$$

The limits in the latter integral are determined from the equations which give the limits in the former.

For example, to find the volume comprised between the plane of xy, the hyperbolic paraboloid $cz = xy$, and the right cylinder $(x-a)^2 + (y-b)^2 = k^2$.

Here $$\mathrm{V} = \frac{1}{c}\iint xydxdy\,,$$

extended to all values of x, y, subject to the condition

$$(x-a)^2 + (y-b)^2 < k^2\,.$$

Assuming the origin of polar co-ordinates at the point a, b, and transforming the equation, we get

$$\mathrm{V} = \frac{1}{c}\int_0^{k}\int_0^{2\pi}(a + r\cos\theta)(b + r\sin\theta)rdrd\theta = \frac{\pi abk^2}{c}\,,$$

since

$$\int_0^{2\pi}\sin\theta\,d\theta = 0,\ \int_0^{2\pi}\cos\theta\,d\theta = 0,\ \int_0^{2\pi}\sin\theta\cos\theta\,d\theta = 0\,.$$

177. The triple integral

$$\iiint f(x,\,y,\,z)dxdydz,$$

can be transformed in like manner.

For, first, take

$$x = \rho\cos\phi,\ y = \rho\sin\phi\,,$$

and the integral transforms into

$$\iiint f(\rho\cos\phi,\,\rho\sin\phi,\,z)\rho d\rho dzd\phi\,.$$

Again, assume $z = r\cos\theta$, $\rho = r\sin\theta$, and the multiple integral becomes

$$\iiint f(r\sin\theta\cos\phi,\ r\sin\theta\sin\phi,\ r\cos\theta)r^2\sin\theta\, drd\theta d\phi\,.$$

With respect to the limits in the new integral, it may be observed that, in this and all other cases, the new limits must be taken in such a manner that the transformed multiple integral shall comprise every element which enters into the original integral, and no more.

In particular the volume of any solid is represented by

$$\iiint r^2\sin\theta\, drd\theta d\phi\,,$$

taken between limits determined by the boundary of the solid.

If this expression be integrated with respect to r, we have

$$\mathrm{V} = \tfrac{1}{3}\iint r^3\sin\theta\, d\theta d\phi\,,$$

in which we must substitute for r its value determined by the equation of the bounding surface.

For example, let us investigate the volume within the surface

$$(x^2+y^2+z^2)^5 = (a^3x^2+b^3y^2+c^3z^2)^2.$$

Here we get

$$r^3 = a^3\sin^2\theta\cos^2\phi + b^3\sin^2\theta\sin^2\phi + c^3\cos^2\theta\,,$$

and, as the equation is symmetrical, we have

$$\mathrm{V} = \tfrac{8}{3}\int_0^{\frac{\pi}{2}}\int_0^{\frac{\pi}{2}}$$

$$(a^3\sin^2\theta\cos^2\phi + b^3\sin^2\theta\sin^2\phi + c^3\cos^2\theta)\sin\theta\, d\theta d\phi$$

$$= \tfrac{8}{9}\int_0^{\frac{\pi}{2}}(2a^3\cos^2\phi + 2b^3\sin^2\phi + c^3)d\phi = \frac{4\pi}{9}(a^3+b^3+c^3)\,.$$

Again, the expresssion for the volume of the ellipsoid

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1$$

is represented by the integral

$$\tfrac{8}{3}\int_0^{\frac{\pi}{2}}\int_0^{\frac{\pi}{2}}\frac{\sin\theta\, d\theta d\phi}{\left\{\dfrac{\sin^2\theta\cos^2\phi}{a^2}+\dfrac{\sin^2\theta\sin^2\phi}{b^2}+\dfrac{\cos^2\theta}{c^2}\right\}^{\frac{3}{2}}}\,.$$

Hence, since the volume of the ellipsoid is $\frac{4}{3}\pi abc$, we get

$$\int_0^{\frac{\pi}{2}}\int_0^{\frac{\pi}{2}}\frac{\sin\theta\, d\theta d\phi}{\left\{\dfrac{\sin^2\theta\cos^2\phi}{a^2}+\dfrac{\sin^2\theta\sin^2\phi}{b^2}+\dfrac{\cos^2\theta}{c^2}\right\}^{\frac{3}{2}}} = \frac{\pi abc}{2}\,,$$

a result which admits of a direct demonstration.

178. The multiple integral

$$u = \iiiint \mathrm{V}dx_1dx_2dx_3dx_4$$

admits of a like transformation.

For, let $x_1 = \rho_1\cos\phi$, $x_2 = \rho_1\sin\phi$, and it becomes

$$\iiiint \mathrm{V}_1\rho_1 d\rho_1 d\phi dx_3 dx_4\,,$$

where V_1 represents the transformed value of V.

In like manner, if $x_3 = \rho_2\cos\psi$, $x_4 = \rho_2\sin\psi$, the transformed integral may be written

$$\iiiint \mathrm{V}_2\rho_1\rho_2 d\rho_1 d\rho_2 d\phi d\psi\,.$$

Again, if $\rho_1 = r\cos\theta$, $\rho_2 = r\sin\theta$, the integral assumes the form

$$\iiiint \mathrm{V}_3 r^3\sin\theta\cos\theta\, drd\theta d\phi d\psi\,,$$

where V_3 represents the final form of V. In this case the values of x_1, x_2, x_3, x_4, in terms of the new variables, are

$$x_1 = r\cos\theta\cos\phi,\quad x_3 = r\sin\theta\cos\psi\,,$$

$$x_2 = r\cos\theta\sin\phi,\quad x_4 = r\sin\theta\sin\psi\,.$$

Quadrature of Surfaces.

179. It is readily shown that the area of any cylindrical surface, bounded by two planes perpendicular to its axis, is equal to the rectangle under the height of the cylinder and the perimeter of its base; also that the surface of a truncated right cone is equal to the rectangle under its mean section and the length of the portion of any edge of the cone intercepted between the bounding sections.

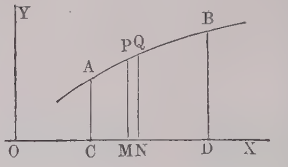

Fig. 11.

In the evaluation of the superficial area of a solid of revolution, we proceed, as in § 172, by supposing the surface divided by planes perpendicular to the axis of revolution (fig. 11). Then the elementary portion of surface between two indefinitely near planes may be regarded as a portion of the surface of a right cone, generated by the revolution of the corresponding element of the curve round the axis. Hence, denoting the element PQ by ds, and PM by y, the area generated by PQ in a complete revolution round the axis of x is represented in the limit by $2\pi yds$. Consequently, if S be the surface generated by the curve AB, we have

$$\mathrm{S} = 2\pi\int yds\,,$$

taken between limits corresponding to the points A and B.

(1) Thus for the sphere, generated by the revolution of the circle $x^2+y^2=a^2$ round the axis of x, we have

$$ds = \left\{1+\left(\frac{dy}{dx}\right)^2\right\}^{\frac{1}{2}}dx = \left(1+\frac{x^2}{y^2}\right)^{\frac{1}{2}}dx = \frac{a}{y}dx\,.$$

Hence $\mathrm{S} = 2\pi\int adx = 2\pi a(\mathrm{X}-x_0)$, if X, x_0 be the limits for x.

Accordingly, the whole surface is $4\pi a^2$, *i.e.*, four times the area of one of the great circles of the sphere. Also the surface bounded by any two parallel planes is equal to the corresponding surface cut out of the circumscribed cylinder, whose axis is perpendicular to the bounding planes.

(2) If the ellipse

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$$

revolve round the axis of x, we have

$$ds = \left(1+\frac{b^4}{a^4}\,\frac{x^2}{y^2}\right)^{\frac{1}{2}}dx\,;$$

$$\therefore\quad yds = \frac{b}{a}\left(a^2-e^2x^2\right)^{\frac{1}{2}}dx\,,$$

where e is the eccentricity of the ellipse.

Hence, the whole surface of this ellipsoid is

$$4\pi\frac{b}{a}\int_0^a (a^2-e^2x^2)^{\frac{1}{2}}dx = 2\pi b^2 + 2\pi\frac{ab}{e}\sin^{-1}e\,.$$

In like manner, if S be the surface generated by the revolution of the ellipse round its axis minor, we get

$$\mathrm{S} = 2\pi\int xds = 2\pi\frac{a}{b^2}\int(b^4+a^2e^2y^2)^{\frac{1}{2}}dy\,.$$

Consequently its entire surface is represented by

$$2\pi a^2 + \pi\frac{b^2}{e}\log\left(\frac{1+e}{1-e}\right)\cdot$$

180. In connection with surfaces of revolution, the following general propositions, usually called Guldin's theorems, may be here stated.

(1) If a plane curve revolve round any external axis situated in its plane, the area of the surface generated in a complete revolution equals the product of the length of the generating curve into the path described by its centre of gravity.

(2) In like manner, the volume of the solid generated is equal to the product of the generating area into the path described by the centre of gravity of the area.

The former of these theorems is easily shown; for if y_1 be the distance of the centre of gravity of the curve from the axis of revolution, taken as that of x, we have

$$y_1 s = \int yds\,;$$

$$\therefore\quad 2\pi y_1 s = 2\pi\int yds = \mathrm{S}\,,$$

which proves the theorem.

Next, if y_2 be the ordinate of the centre of gravity of the area A, we have

$$\mathrm{A}y_2 = \Sigma y d\mathrm{A} = \iint ydxdy = \tfrac{1}{2}\int y^2dx\,,$$

$$\therefore\quad 2\pi y_2\mathrm{A} = \pi\int y^2dx\,,$$

whence the latter theorem follows.

181. In the general case of the determination of the quadrature of a surface we regard it as a limit of a number of indefinitely small elements, each of which is considered a portion of a plane that is ultimately a tangent

plane to the surface. Now let dS denote such an element at any point of the surface, and $d\sigma$ its projection on a fixed plane, which makes the angle θ with the tangent plane at the point, then we have

$$d\sigma = dS \cos\theta, \text{ or } dS = \sec\theta \, d\sigma.$$

Hence $$S = \int \sec\theta d\sigma,$$

taken between proper limits.

If now the surface be referred to a rectangular system of co-ordinate axes, we may take $d\sigma = dxdy$; also, from an elementary theorem in surfaces,

$$\sec\theta = \sqrt{1+p^2+q^2}, \text{ where } p = \frac{dz}{dx}, \; q = \frac{dz}{dy}.$$

Hence we have

$$S = \iint (1+p^2+q^2)^{\frac{1}{2}} dxdy,$$

in which the values of p and q are to be determined from the equation of the surface.

(1) For example, let it be proposed to find the portion of the surface of a sphere intercepted by a cone of the second order, whose vertex is on the surface of the sphere, and whose internal axis passes through the centre of the sphere.

Let O the vertex of the cone be taken as the origin (fig. 12), and the line joining it to the centre of the sphere as axis of z, then the equation of the sphere may be written

$$x^2+y^2+z^2 = 2az.$$

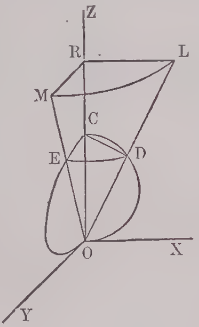

Fig. 12.

Hence

$$p = \frac{dz}{dx} = \frac{x}{a-z}, \; q = \frac{dz}{dy} = \frac{y}{a-z};$$

$$\therefore \sqrt{1+p^2+q^2} = \frac{a}{a-z};$$

consequently

$$S = a\iint \frac{dxdy}{\sqrt{a^2-x^2-y^2}},$$

in which the limits are determined from the equation of the bounding cone. Let the equation of this cone be

$$z^2 = A^2x^2 + B^2y^2;$$

then, eliminating z, the limiting values of x and y are connected by the equation

$$(1+A^2)x^2 + (1+B^2)y^2 = 2a\sqrt{A^2x^2+B^2y^2}.$$

Next, transform to polar co-ordinates by making

$$x = r\cos\theta, \; y = r\sin\theta,$$

and we get

$$S = a\iint \frac{rdrd\theta}{\sqrt{a^2-r^2}},$$

taken for all points within the curve

$$r\left\{(1+A^2)\cos^2\theta + (1+B^2)\sin^2\theta\right\} = 2a\sqrt{A^2\cos^2\theta + B^2\sin^2\theta}.$$

Hence, since the curve is symmetrical, we get

$$S = 4a\int_0^{\frac{\pi}{2}}\int_0^R \frac{rdrd\theta}{\sqrt{a^2-r^2}},$$

where $$R = \frac{2a\sqrt{A^2\cos^2\theta + B^2\sin^2\theta}}{1+A^2\cos^2\theta + B^2\sin^2\theta}.$$

Again

$$\int_0^R \frac{rdr}{\sqrt{a^2-r^2}} = a - \sqrt{a^2-R^2} = \frac{2a}{1+A^2\cos^2\theta + B^2\sin^2\theta};$$

$$\therefore \quad S = 8a^2\int_0^{\frac{\pi}{2}} \frac{d\theta}{(1+A^2)\cos^2\theta + (1+B^2)\sin^2\theta} = \frac{4\pi a^2}{\sqrt{(1+A^2)(1+B^2)}}.$$

This result admits of a simple geometrical representation; for let D, E (fig. 12) be the points in which the edges of the cone lying in the planes $y=0$ and $x=0$ cut the surface of the sphere, and we plainly have

$$CD = \frac{2a}{\sqrt{1+A^2}}, \; CE = \frac{2a}{\sqrt{1+B^2}}.$$

Consequently the area of the intercepted portion of the sphere is equal to that of the ellipse which has CD and CE as its semi-axes.

(2) If, instead of the cone, we had taken the paraboloid

$$z = Ax^2 + By^2,$$

the area of the portion intercepted on the sphere is given, as in the preceding, by the equation

$$S = 4a\int_0^{\frac{\pi}{2}} (a - \sqrt{a^2-R^2})\, d\theta,$$

where, from the equation of the bounding curve, we have

$$R^2 \quad \frac{2a(A\cos^2\theta + B\sin^2\theta) - 1}{(A\cos^2\theta + B\sin^2\theta)^2}.$$

Hence $$S = 4a\int_0^{\frac{\pi}{2}} \frac{d\theta}{A\cos^2\theta + B\sin^2\theta} = \frac{2\pi a}{\sqrt{AB}}.$$

This result admits of a geometrical interpretation similar to that in example (1).

Multiple Integrals.

182. The general form of a multiple integral may be represented by the expression

$$\int_{x_0}^{X} dx \int_{y_0}^{Y} dy \ldots \int_{u_0}^{U} du \int_{t_0}^{T} dt f(x, y, \ldots u, t),$$

in which $f(x, y, \ldots u, t)$ is supposed continuous for all systems of values of the independent variables $x, y, \ldots u, t$ included within the limits. Moreover the limits of each variable must be independent of the *following* variables, but may depend on the *preceding* variables.

In calculating the integral, the expression $f(x, y, \ldots u, t)dt$ is integrated between the limits T and t_0, regarding $x, y, \ldots u$ as constants. Thus we obtain a function of $x, y, \ldots u$. This function is integrated with respect to u between the limits U and u_0, treating $x, y \ldots$ as constant. We thus obtain a function of $x, y, \ldots$ independent of u, t; and so on for the subsequent integrations.

If the limits for each variable be constant, the integrations may be taken in any order, subject to such limitations as those given in § 148 for two variables. In the more general case, when the order of integration is altered it is necessary to determine, from the conditions of the problem, the new limiting values. This is usually a matter of much difficulty.

183. Continuing from § 178, the general problem of the *transformation of a multiple integral* by a change of variables may be stated as follows.

Suppose the multiple integral represented by

$$\iint \ldots \int \phi(x_1, x_2, \ldots x_n) dx_1 \, dx_2 \ldots dx_n,$$

and it be proposed to transform it into another, depending on new variables $u_1, u_2, \ldots u_n$, which are related with the original variables by a system of n given equations. This transformation implies three parts in general: (1) the determination of $\phi(x_1, x_2, \ldots x_n)$ in terms of $u_1, u_2, \ldots u_n$; (2) the determination of the new system of limits; (3) the finding the substitution for $dx_1 \, dx_2 \ldots dx_n$.

The solution of the first two questions is an algebraical problem, of which we have already considered one or two elementary cases. We now address ourselves to the third question, and write the integral in the form

$$\int dx_1 \int dx_2 \ldots \int dx_{n-1} \int dx_n \phi(x_1, x_2 \ldots).$$

In the integration with respect to x_n, as stated in § 182, $x_1, x_2, \ldots x_{n-1}$ are regarded as constants. Accordingly, in order to replace x_n by u_n, it is sufficient to express x_n in terms of $u_n, x_1, x_2, \ldots x_{n-1}$, and then to substitute $\frac{dx_n}{du_n}du_n$ for dx_n. Again, to transform the next integration, relative to dx_{n-1}, we suppose x_{n-1} expressed in terms of $u_{n-1}, u_n, x_1, x_2, \ldots x_{n-2}$, and we replace dx_{n-1} by $\frac{dx_{n-1}}{du_{n-1}}du_{n-1}$. By continuing this process the integral finally becomes of the form

$$\iiint \ldots \int \phi_1 \frac{dx_n}{du_n}\frac{dx_{n-1}}{du_{n-1}} \ldots \frac{dx_1}{du_1} du_1 du_2 \ldots du_n,$$

where ϕ_1 represents the value of $\phi(x_1, x_2, \ldots x_n)$ when transformed into a function of $u_1, u_2, \ldots u_n$.

Moreover, by § 102, the product

$$\frac{dx_n}{du_n}\frac{dx_{n-1}}{du_{n-1}} \ldots \frac{dx_1}{du_1}$$

is, in this case, the Jacobian of the original system of variables $x_1, x_2, \ldots x_n$ regarded as functions of the new variables.

Accordingly, for $dx_1, dx_2 \ldots dx_n$ we substitute

$$\begin{vmatrix} \frac{dx_1}{du_1} & \frac{dx_1}{du_2} & \ldots & \frac{dx_1}{du_n} \\ \frac{dx_2}{du_1} & \frac{dx_2}{du_2} & \ldots & \frac{dx_2}{du_n} \\ \ldots & \ldots & \ldots & \ldots \\ \frac{dx_n}{du_1} & \frac{dx_n}{du_2} & \ldots & \frac{dx_n}{du_n} \end{vmatrix} du_1 du_2 \ldots du_n.$$

For instance, if $\iint V dxdy$ be transformed to new variables u, v, denoting by V_1 the value which V assumes, the double integral becomes

$$\iint V_1(x'_u y'_v - y'_u x'_v) dxdy,$$

where $x'_u = \frac{dx}{du},\ y'_u = \frac{dy}{du},\ x'_v = \frac{dx}{dv},\ y'_v = \frac{dy}{dv}$.

Again, if the co-ordinates of each point on a surface be given in terms of two independent variables u, v, to find the transformed expression for the superficial area

$$\iint \sqrt{1 + \left(\frac{dz}{dx}\right)^2 + \left(\frac{dz}{dy}\right)^2}\, dxdy.$$

Here $dxdy$ becomes $(x' \ y'_v - y'_u x'_v)\, dudv$ as before.

Also, since, from the equation to the surface, z may be regarded as a function of x and y, we have

$$z'_u = x'_u \frac{dz}{dx} + y'_u \frac{dz}{dy},\ z'_v = x'_v \frac{dz}{dx} + y'_v \frac{dz}{dy};$$

$$\therefore\ \frac{dz}{dx} = \frac{z'_u y'_v - y'_u z'_v}{x'_u y'_v - y'_u x'_v},\ \frac{dz}{dy} = \frac{x'_u z'_v - z'_u x'_v}{x'_u y'_v - y'_u x'_v}.$$

Accordingly the transformed expression is

$$\iint \left\{ (x'_u y'_v - y'_u x'_v)^2 + (y'_u z'_v - z'_u y'_v)^2 + (z'_u x'_v - x'_u z'_v)^2 \right\}^{\frac{1}{2}} dudv.$$

For example, the co-ordinates of any point on the ellipsoid

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$$

may be represented by the equations

$$x = a \sin\theta \cos\phi,\ y = b \sin\theta \sin\phi,\ z = c \cos\theta;$$

hence it can be shown that its total surface S is represented by

$$S = abc \int_0^{\pi} \int_0^{2\pi}$$

$$\sin\phi\, d\theta d\phi \left\{ \frac{\cos^2\theta}{c^2} + \frac{\sin^2\theta \sin^2\phi}{b^2} + \frac{\sin^2\theta \cos^2\phi}{a^2} \right\}^{\frac{1}{2}};$$

in which the integration with respect to θ can be immediately effected.

Again, the co-ordinates of any point on a sphere of radius a can be represented by the equations

$$x = a \sin\theta \sqrt{1 - k^2 \sin^2\phi},\ y = a \sin\phi \sqrt{1 - k'^2 \sin^2\theta},$$

$$z = a \cos\theta \cos\phi, \text{ where } k^2 + k'^2 = 1.$$

This is obvious, since the sum of the squares of these expressions is a^2.

Accordingly

$$x'_\theta y'_\phi - y'_\theta x'_\phi = -\frac{a^2 \cos\theta \cos\phi (k^2 \cos^2\phi + k'^2 \cos^2\theta)}{\sqrt{1 - k^2 \sin^2\phi}\ \sqrt{1 - k'^2 \sin^2\theta}},$$

$$y'_\theta z'_\phi - z'_\theta y'_\phi = \frac{a^2 \sin\theta\, (k^2 \cos^2\phi + k'^2 \cos^2\theta)}{\sqrt{1 - k'^2 \sin^2\theta}}$$

$$z'_\theta x'_\phi - x'_\theta z'_\phi = \frac{a^2 \sin\phi (k^2 \cos^2\phi + k'^2 \cos^2\theta)}{\sqrt{1 - k^2 \sin^2\phi}}.$$

Hence we get

$$dS = \frac{a^2(k^2 \cos^2\phi + k'^2 \cos^2\theta)}{\sqrt{1 - k^2 \sin^2\phi}\ \sqrt{1 - k'^2 \sin^2\theta}} d\theta d\phi.$$

Consequently, since the entire surface of the sphere is $4\pi a^2$, we have

$$\int_0^{\frac{\pi}{2}} \int_0^{\frac{\pi}{2}} \frac{(k^2 \cos^2\phi + k'^2 \cos^2\theta) d\theta d\phi}{\sqrt{1 - k^2 \sin^2\phi}\ \sqrt{1 - k'^2 \sin^2\theta}} = \frac{\pi}{2}.$$

The well-known general formula of Legendre, connecting complete elliptic functions of the first and second species, follows at once from this last result.

184. In the case of three variables, adopting a similar notation, the integral

$$\iiint V dxdydz$$

transforms into

$$\iiint V_1 \left\{ z'_w(x'_u y'_v - y'_u x'_v) + y'_w(z'_u x'_v - x'_u z'_v) + x'_w(y'_u z_v - z'_u y'_v) \right\} dudvdw.$$

For example, in the general transformation from rectangular to polar co-ordinates we find, as already observed, that $r^2 \sin\theta dr d\theta d\phi$ is to be substituted for the element of volume $dxdydz$. This is but a particular case of the general transformation given in § 103.

The preceding formula of transformation for three variables was given by Euler in 1769, and afterwards generalized by Lagrange in 1773. Jacobi appears, however, to have been the first to have established the general transformation, in his memoir referred to in § 96. The method of proof here adopted is that given by Bertrand.

Ex. 1. In the case of linear transformations, viz., when

$$x_1 = a_1 u_1 + a_2 u_2 + \ldots + a_n u_n,$$
$$x_2 = b_1 u_1 + b_2 u_2 + \ldots + b_n u_n,$$
$$\ldots\ldots\ldots\ldots$$
$$x_n = l_1 u_1 + l_2 u_2 + \ldots + l_n u_n,$$

we get $dx_1 dx_2 \ldots dx_n = \Delta du_1 du_2 \ldots du_n$,

where
$$\Delta = \begin{vmatrix} a_1 & a_2 & \ldots & a_n \\ b_1 & b_2 & \ldots & b_n \\ \ldots & \ldots & \ldots & \ldots \\ l_1 & l_2 & \ldots & l_n \end{vmatrix}.$$

Ex. 2. If $x_1 = \frac{u_2 u_3}{u_1},\ x_2 = \frac{u_1 u_3}{u_2},\ x_3 = \frac{u_1 u_2}{u_3}$,

the Jacobian is

$$\begin{vmatrix} -\frac{u_2 u_3}{u_1^2} & \frac{u_3}{u_1} & \frac{u_2}{u_1} \\ \frac{u_3}{u_2} & -\frac{u_1 u_3}{u_2^2} & \frac{u_1}{u_2} \\ \frac{u_2}{u_3} & \frac{u_1}{u_3} & -\frac{u_1 u_2}{u_3^2} \end{vmatrix}.$$

The value of this determinant is easily seen to be 4; hence

$$\iiint V dx_1 dx_2 dx_3 \text{ transforms into } 4\iiint V_1 du_1 du_2 du_3.$$

Ex. 3. As an additional example we shall take Jacobi's method of establishing the fundamental formula of Eulerian integrals (§ 153).

Since

$$\Gamma(l) = \int_0^\infty e^{-x} x^{l-1} dx,\ \Gamma(m) = \int_0^\infty e^{-y} y^{m-1} dy,$$

we have

$$\Gamma(l)\Gamma(m) = \int_0^\infty \int_0^\infty e^{-x-y} x^{l-1} y^{m-1} dxdy.$$

If now we transform by making $x = uv$, $y = u(1 - v)$, the limits for u are 0 and ∞, and those for v are 0 and 1;

also
$$\frac{dx}{dv}\frac{dy}{du} - \frac{dx}{du}\frac{dy}{dv} = u;$$

hence
$$\Gamma(l)\Gamma(m) = \int_0^\infty \int_0^1 e^{-u} u^{l+m-1} v^{l-1} (1-v)^{m-1} dudv$$
$$= \Gamma(l+m) \int_0^1 v^{l-1}(1-v)^{m-1} dv,$$
$$\therefore \int_0^1 v^{l-1}(1-v)^{m-1} dv = \frac{\Gamma(l)\Gamma(m)}{\Gamma(l+m)}.$$

185. In the more general case, where $x_1, x_2 \ldots x_n$ are not given explicitly in terms of $u_1, u_2 \ldots u_n$, but are connected with them by n equations of the form

$$F_1(x_1, x_2 \ldots x_n, u_1, u_2 \ldots u_n) = 0,\ F_2(x_1, x_2 \ldots x_n, u_1, u_2 \ldots u_n) = 0,$$
$$\ldots\ldots\ldots\ldots$$
$$F_{n-1}(x_1, x_2 \ldots x_n, u_1, u_2 \ldots u_n) = 0,\ F_n(x_1, x_2 \ldots x_n, u_1, u_2 \ldots u_n) = 0,$$

we get, by § 99,

$$\begin{vmatrix} \frac{dx_1}{du_1} & \frac{dx_1}{du_2} & \ldots & \frac{dx_1}{du_n} \\ \frac{dx_2}{du_1} & \frac{dx_2}{du_2} & \ldots & \frac{dx_2}{du_n} \\ \ldots & \ldots & \ldots & \ldots \\ \frac{dx_n}{du_1} & \frac{dx_n}{du_2} & \ldots & \frac{dx_n}{du_n} \end{vmatrix} = \frac{\Delta_1}{\Delta_2},$$

where

$$\Delta_1 = \begin{vmatrix} \frac{dF_1}{du_1} & \frac{dF_1}{du_2} & \dots & \frac{dF_1}{du_n} \\ \frac{dF_2}{du_1} & \frac{dF_2}{du_2} & \dots & \frac{dF_2}{du_n} \\ \cdot & \cdot & \cdot & \cdot \\ \frac{dF_n}{du_1} & \frac{dF_n}{du_2} & \dots & \frac{dF_n}{du_n} \end{vmatrix}, \quad \Delta_2 = \begin{vmatrix} \frac{dF_1}{dx_1} & \frac{dF_1}{dx_2} & \dots & \frac{dF_1}{dx_n} \\ \frac{dF_2}{dx_1} & \frac{dF_2}{dx_2} & \dots & \frac{dF_2}{dx_n} \\ \cdot & \cdot & \cdot & \cdot \\ \frac{dF_n}{dx_1} & \frac{dF_n}{dx_2} & \dots & \frac{dF_n}{dx_n} \end{vmatrix}.$$

Accordingly the multiple integral

$$\iiint \dots \int V dx_1 dx_2 \dots dx_n$$

transforms into

$$\iiint \dots \int V_1 \frac{\Delta_1}{\Delta_2} du_1 du_2 \dots du_n.$$

The limits in the transformed integral are determined by aid of the equations which give the limits in the original.

186. We conclude this short account of multiple integrals with a notice of the very general and remarkable theorems relative to integrals extended through a closed surface first given by Green (*Essay on the Application of Mathematics to Electricity and Magnetism*, Nottingham, 1828).

Let U, V denote two functions of the rectangular co-ordinates x, y, z which are finite, and have their first differential coefficients finite, for all points within a closed surface; then, since

$$\frac{d}{dx}\left(U\frac{dV}{dx}\right) = \frac{dU}{dx}\frac{dV}{dx} + U\frac{d^2V}{dx^2},$$

we have

$$\iiint \frac{d}{dx}\left(U\frac{dV}{dx}\right)dxdydz = \iiint \frac{dU}{dx}\frac{dV}{dx}dxdydz + \iiint U\frac{d^2V}{dx^2}dxdydz,$$

the integrals being extended to all points within the surface.

Also, since the bounding surface is closed, any right line which meets the bounding surface, must cut it in an even number of points; hence the integral

$$\iiint \frac{d}{dx}\left(U\frac{dV}{dx}\right)dxdydz = \iint dydz\Sigma\left(U_2\frac{dV_2}{dx_2} - U_1\frac{dV_1}{dx_1}\right)$$

where x_2, x_1, U_2, U_1, etc., are the values of x, etc., for two corresponding points of intersection with the boundary by the infinitely thin cylinder standing on $dydz$, and by Σ is denoted the summation taken for all such values. Again, if dS_2, dS_1 be the corresponding elements of surface, and α_2, α_1 the angles which the exterior normal to the surface at each of these points makes with the positive direction of the axis of x, we have

$$dydz = \cos\alpha_2\, dS_2 = -\cos\alpha_1\, dS_1;$$

hence it is readily seen that the integral

$$\iint dydz\Sigma\left(U_2\frac{dV_2}{dx_2} - U_1\frac{dV_1}{dx_1}\right)$$

is equal to

$$\iint U\frac{dV}{dx}\cos\alpha\, dS,$$

taken for every element of the boundary, whether it consist of one closed surface or of several.

Accordingly, we get

$$\iiint U\frac{d^2V}{dx^2}dxdydz + \iiint \frac{dU}{dx}\frac{dV}{dx}dxdydz = \iint U\frac{dV}{dx}\cos\alpha\, dS,$$

in which the former integrals are taken for every point within any space, and the latter integral taken for each point on the boundary of that space. This may be written

$$\iiint \frac{dU}{dx}\frac{dV}{dx}dxdydz = \iint U\frac{dV}{dx}\cos\alpha\, dS - \iiint U\frac{d^2V}{dx^2}dxdydz.$$

Taking the coresponding equations relative to y and z, we have by addition,

$$\iiint\left(\frac{dU}{dx}\frac{dV}{dx} + \frac{dU}{dy}\frac{dV}{dy} + \frac{dU}{dz}\frac{dV}{dz}\right)dxdydz$$
$$= \iint U\left(\frac{dV}{dx}\cos\alpha + \frac{dV}{dy}\cos\beta + \frac{dV}{dz}\cos\gamma\right)dS$$
$$- \iiint U\left(\frac{d^2V}{dx^2} + \frac{d^2V}{dy^2} + \frac{d^2V}{dz^2}\right)dxdydz.$$

Again, if dn be the element of the normal, measured outwards, at the element dS, we readily get

$$\cos\alpha = \frac{dx}{dn}, \quad \cos\beta = \frac{dy}{dn}, \quad \cos\gamma = \frac{dz}{dn};$$

$$\therefore \quad \frac{dV}{dx}\cos\alpha + \frac{dV}{dy}\cos\beta + \frac{dV}{dz}\cos\gamma = \frac{dV}{dn}.$$

Hence

$$\iiint\left(\frac{dU}{dx}\frac{dV}{dx} + \frac{dU}{dy}\frac{dV}{dy} + \frac{dU}{dz}\frac{dV}{dz}\right)dxdydz$$
$$= \iint U\frac{dV}{dn}dS - \iiint U\left(\frac{d^2V}{dx^2} + \frac{d^2V}{dy^2} + \frac{d^2V}{dz^2}\right)dxdydz$$
$$= \iint V\frac{dU}{dn}dS - \iiint V\left(\frac{d^2U}{dx^2} + \frac{d^2U}{dy^2} + \frac{d^2U}{dz^2}\right)dxdydz.$$

The latter equation is obtained by an interchange of U and V.

This is Green's fundamental theorem, in the case where U and V are continuous functions.

187. The modification when one of the functions, U for example, becomes infinite for a point within the surface was also investigated by Green. Suppose this to happen at one point, P, only; moreover, infinitely near to P let U be sensibly $= \frac{1}{r}$, r being the distance from P. Next suppose an indefinitely small sphere, of radius a, described with P as centre. Then it is clear that Green's equation holds for all the space exterior to this sphere. Also, since

$$\left(\frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2}\right)\frac{1}{r} = 0,$$

the triple integrals may be extended throughout the entire space. Moreover, the part of $\iint U\frac{dV}{dn}dS$ due to the surface of the sphere is plainly infinitely small of the order of a. It only remains to consider the value of $\iint V\frac{dU}{dn}dS$ taken over the surface of the sphere.

But, since $\frac{dU}{dn} = -\frac{1}{a^2}$, this becomes $-4\pi V_1$, where V_1 is the value of V at the point P.

Hence, denoting

$$\frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2} \text{ by } \nabla_2,$$

we have

$$\iiint dxdydz U\nabla_2 V - \iint U\frac{dV}{dn}dS$$
$$= \iiint dxdydz V\nabla_2 U - \iint V\frac{dU}{dn}dS + 4\pi V_1,$$

where, as before, the double integrals are extended over the bounding surface or surfaces, and the triple integrals taken throughout the entire space enclosed.

These theorems of Green have been generalized by Sir W. Thomson; thus, if α be another continuous function of x, y, z, we get, by a similar treatment, instead of Green's first equations,

$$\iiint \alpha^2\left(\frac{dU}{dx}\frac{dV}{dx} + \frac{dU}{dy}\frac{dV}{dy} + \frac{dU}{dz}\frac{dV}{dz}\right)dxdydz$$
$$= \iint \alpha^2 V\frac{dU}{dn}dS - \iiint V\left\{\frac{d}{dx}\left(\alpha^2\frac{dU}{dx}\right) + \frac{d}{dy}\left(\alpha^2\frac{dU}{dy}\right) + \frac{d}{dz}\left(\alpha^2\frac{dU}{dz}\right)\right\}dxdydz$$
$$= \iint \alpha^2 U\frac{dV}{dn}dS - \iiint U\left\{\frac{d}{dx}\left(\alpha^2\frac{dV}{dx}\right) + \frac{d}{dy}\left(\alpha^2\frac{dV}{dy}\right) + \frac{d}{dz}\left(\alpha^2\frac{dV}{dz}\right)\right\}dxdydz,$$

with a corresponding modification when one of the functions becomes infinite at one or more interior points.

In the case of many-valued functions, another modification of Green's theorem was established by Helmholtz ("Ueber Integrale der Hydrodynamischen Gleichungen welche den Wirbelbewegungen entsprechen," *Crelle*, 1858).

Elliptic Integrals.

188. Attention has hitherto been restricted to integrations of rational algebraic functions, of logarithmic or circular functions, or of such functions as could be transformed to depend on these; or, if irrationalities were introduced, they were such as involved the variable under the radical in no higher than the second degree. But the founders of

the infinitesimal calculus early perceived that many integrals did not admit of expression by means of these elementary functions with which they were familiar. Apparently it was the geometrical interest attached to such integrations which first attracted notice. Thus James Bernoulli published, in the *Acta Eruditorum* for 1691, a paper on the helicoidal parabola, in which we meet with the idea of comparing arcs of one and the same curve, which cannot be superposed.

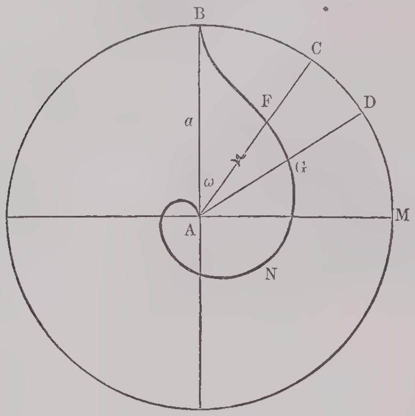

Fig. 13.

This spiral is the locus of the extremities of the ordinates of a parabola when its axis is rolled as a tangent to a fixed circle, the ordinates being measured towards the centre. The polar equation of the locus is $(a-r)^2=2ab\omega$ (see fig. 13). Hence the arc $ds = dr$

$$\sqrt{1+\frac{r^2(a-r)^2}{a^2b^2}}\,;$$

so that, if s_1 be the arc contained between the values $\frac{1}{2}a$ and $\frac{1}{2}a+c$ (= AG) of r, and s_2 the arc between the values $\frac{1}{2}a-c$ (= AN) and $\frac{1}{2}a$, we have

$$s_1=\int_{\frac{a}{2}}^{\frac{a}{2}+c}\sqrt{1+\frac{r^2(a-r)^2}{a^2b^2}}\,dr,\ s_2=\int_{\frac{a}{2}-c}^{\frac{a}{2}}\sqrt{1+\frac{r^2(a-r)^2}{a^2b^2}}\,dr.$$

Now, putting in the former $r=\frac{1}{2}a+z$, and in the latter $r=\frac{1}{2}a-z$, we find

$$s_1=s_2=\int_0^c\sqrt{1+\frac{1}{a^2b^2}\left(z^2-\frac{a^2}{4}\right)^2}\,dz;$$

whence we conclude, as Bernoulli did, that even in curves whose rectification has not yet been effected, parts may be assigned which are equal though dissimilar; such as BG=AN, and GI=NI, where AI$=\frac{1}{2}a$.

John Bernoulli, following up this discovery of his brother, proposed to find for a given curve another, such that the sum or the difference of two arcs, one on each curve, may be expressed by arcs of circles. In the case of the cubical parabola he noticed that the two curves reduce to one curve, in which, without effecting the rectification, pairs of arcs could be found whose difference is rectifiable.

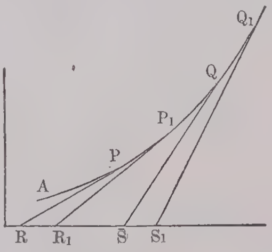

Fig. 14.

189. The Count Fagnani next proposed in 1714 the problem, "given a portion of the parabola whose equation is $x^4=y$, to find another portion of it such that the difference of these two parts may be rectifiable. In the following year, not having received a solution, Fagnani published his own, with greater generality, as follows. Taking a constant, and m any real number, let $y=\frac{2}{m+2}\,\frac{x^{\frac{m+2}{2}}}{a^{\frac{m}{2}}}$ be the equation of a parabolic curve (compare Ex. 2, § 166). Let t be the portion of the tangent between any point (xy) of the curve and the axis of abscissæ.

Then by the equation of the curve,

$$t=\frac{2x}{m+2}\sqrt{1+\left(\frac{x}{a}\right)^m},$$

and the arc of the curve

$$s=\int\sqrt{1+\left(\frac{x}{a}\right)^m}\,dx.$$

Integration by parts gives (see fig. 14)

$$\frac{m}{m+2}\int_{x_0}^{x_1}\frac{dx}{\sqrt{1+\left(\frac{x}{a}\right)^m}}=\text{arc PP}_1-(\text{P}_1\text{R}_1-\text{PR}),$$

if P, P₁ have the abscissæ x_0, x_1; also

$$\frac{m}{m+2}\int_{z_0}^{z_1}\frac{dz}{\sqrt{1+\left(\frac{z}{a}\right)^m}}=\text{arc QQ}_1-(\text{Q}_1\text{S}_1-\text{QS}),$$

if Q, Q₁ have z_0, z_1, as abscissæ.

Now if the former integral can be transformed by introducing a variable z so that the function under the sign of integration may remain unaltered, and thus the former integral may pass into the latter, we may equate arc PP₁ $-$ (P₁R₁ $-$ PR) = arc QQ₁ $-$ (Q₁S₁ $-$ QS). Thus the question is to determine an integral of the differential equation

$$\frac{dx}{\sqrt{1+\left(\frac{x}{a}\right)^m}}=\frac{dz}{\sqrt{1+\left(\frac{z}{a}\right)^m}},$$

or of

$$\frac{dx}{\sqrt{1+\left(\frac{x}{a}\right)^m}}+\frac{dz}{\sqrt{1+\left(\frac{z}{a}\right)^m}}=0.$$

Fagnani gave the following solutions. For $m=4$ the curve is the cubical parabola, and the relation between x and z is $xz=a^2$. For $m=3$ the equation is satisfied by the relation

$$\left(1+\frac{x}{a}\right)\left(1+\frac{z}{a}\right)=3.$$

For $m=6$ the curve is as in the problem proposed, and the relation is

$$\left(\frac{x}{a}\right)^2\left\{2\left(\frac{z}{a}\right)^2-1\right\}=\left(\frac{z}{a}\right)^2-1.$$

190. Passing over Fagnani's investigations relative to the lemniscate,—such as his discoveries of the method of doubling or halving any arc, of dividing the quadrant into equal parts in number 2.2^m, 3.2^m, or 5.2^m, discoveries which prompted to their author the wish, since executed, that on his tomb a lemniscate should be inscribed *in memoriam*,—we must mention his well-known geometrical theorem, that on the circumference of an ellipse, in innumerable ways, pairs of arcs can be determined having their difference expressible by a right line (first published 1716). His method is as follows. If we have h, l, f, g constants, and $(fhx^2z^2)^s+(flx^2)^s+(flz^2)^s+(gl)^s=0$, then, first, the sum

$$\int\frac{dx\sqrt{hx^2+l}}{\sqrt{fx^2+g}}+\int\frac{dz\sqrt{hz^2+l}}{\sqrt{fz^2+g}}=a-\frac{hxz}{\sqrt{-fl}}\text{ if } s=+1\ldots(1);$$

and, secondly, the same sum $=a+\frac{xz\sqrt{-h}}{\sqrt{g}}$ when $s=-1$.

In the former case the relation gives

$$z=\frac{\sqrt{-flx^2-gl}}{\sqrt{fhx^2+fl}}.$$

Introducing this into the first integral, and the corresponding value of x into the second, the sum of the integral becomes

$$\int\frac{dx\sqrt{-l}}{z\sqrt{f}}+\int\frac{dz\sqrt{-l}}{x\sqrt{f}}.$$

But differentiating the relation, and dividing by $2fxz$, we find

$$hzdx+hxdz+l\frac{dx}{z}+l\frac{dz}{x}=0;$$

whence, substituting, the sum is found to be as stated. A like treatment yields the formula when $s=-1$. This theorem is applied in its former part to elliptic arcs. Let us call the axis major $2a$, the parameter p, and the abscissa x; then, if $h=p-2a$, the element of the arc AB (fig. 15) corresponding to the abscissa CD $=x$ can be shown to be

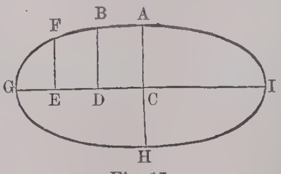

Fig. 15.

$$\frac{dx\sqrt{hx^2+2a^3}}{\sqrt{2a^3-2ax^2}}.$$

If now $l = 2a^3$, $f = -2a$, and $g = 2a^3$, this becomes the former differential in (1); and it appears that, taking another abscissa

$$\text{CE} = z = \frac{a\sqrt{2a^3 - 2ax^2}}{\sqrt{hx^2 - 2a^3}},$$

we have

$$\text{arc AB} + \text{arc AF} = -\frac{hxz}{2a^2} + \text{K}.$$

To determine the value of the constant K, let $x = 0$; then AF becomes the entire arc AG, hence

$$\text{arc AB} - \text{arc GF} = -\frac{hxz}{2a^2}.$$

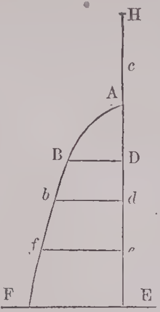

Fig. 16.

The second part of the theorem is applied to the hyperbola (fig. 16). Calling HA $= 2a$, the parameter p, and x the variable abscissa CD, and putting $h = p + 2a$, the element of the arc AB is easily found to be expressed by

$$\frac{dx\sqrt{hx^2 - 2a^3}}{\sqrt{2ax^2 - 2a^3}};$$

whence, identifying, we have $l = -2a^3$, $f = 2a$, $g = -2a^3$, and, assuming another abscissa $\text{CE} = z = \dfrac{a\sqrt{hx^2 - 2a^3}}{\sqrt{hx^2 - ha^2}}$, the theorem gives $\text{arc AB} + \text{arc AF} = \dfrac{xz\sqrt{h}}{a\sqrt{2a}} + \text{K}$.

Taking another pair of abscissæ t, u, similarly related, we have

$$\text{arc A}b + \text{arc A}f = \frac{tu\sqrt{h}}{a\sqrt{2a}} + \text{K},$$

and by subtraction the arbitrary K is eliminated.

191. In order to be able to state the results more concisely, it is desirable here to explain in anticipation the notation introduced by Legendre, which has since generally prevailed.

If the position of a point on an ellipse be expressed by the co-ordinates $x = a \sin\phi$, $y = b \cos\phi$, it can easily be found that, denoting the eccentricity of the ellipse by κ, the arc reckoned from the extremity of the axis minor A to the point B determined by ϕ is expressed by

$$\frac{\text{arc AB}}{a} = \int_0^\phi \sqrt{1 - \kappa^2 \sin^2\phi}\, d\phi.$$

This Legendre writes

$$\frac{\text{arc AB}}{a} = \text{E}(\phi).$$

If it were desired to indicate also the quantity κ, which is called the *modulus* of this elliptic integral, he writes it $\text{E}(\kappa, \phi)$, and calls this an elliptic integral of the *second kind*, for reasons which will soon appear. The quantity ϕ is called the *amplitude* of the elliptic integral, and its geometrical meaning is the eccentric angle measured from the axis minor of the point for which $\text{E}(\kappa, \phi)$ measures the arc. For brevity also he adopted the notation $\sqrt{1 - \kappa^2\sin^2\phi} = \Delta(\kappa, \phi)$, or $= \Delta(\phi)$ when it is unnecessary to mention κ.

192. Legendre, proceeding to rectify the hyperbola $\dfrac{x^2}{\alpha^2} - \dfrac{y^2}{\beta^2} = 1$, first assumes $x = \alpha \sec\theta$, and this gives the element of the arc $= \dfrac{d\theta}{\cos^2\theta}\sqrt{\beta^2 + \alpha^2\sin^2\theta}$; but to have a radical similar to that of the arc of the ellipse he had recourse to another notation. Determining ϕ by the equation $y = \dfrac{\beta^2}{c}\tan\phi$, where $c^2 = \alpha^2 + \beta^2$, we get $x = \dfrac{\alpha\sqrt{1 - \kappa^2\sin^2\phi}}{\cos\phi}$, in which $\alpha = c\kappa$. The arc of the hyperbola is in this way found to be $\dfrac{\beta^2}{c}\displaystyle\int \frac{d\phi}{\cos^2\phi\Delta\phi}$.

Again $d(\tan\phi\Delta\phi) = \dfrac{\kappa'^2 d\phi}{\cos^2\phi\Delta\phi} - \dfrac{\kappa'^2 d\phi}{\Delta\phi} + \Delta\phi d\phi$, where $\kappa^2 + \kappa'^2 = 1$. Hence the hyperbolic arc AB of which the extreme ordinate is BD, or $c\kappa'^2 \tan\phi$, is $\text{AB} = c\Delta\phi\tan\phi - c$

$$\int_0^\phi \Delta\phi d\phi + c\kappa'^2 \int_0^\phi \frac{d\phi}{\Delta\phi}.$$

The geometrical meaning of ϕ is easily determined by taking the circle on the transverse axis, and joining its intersection with the tangent at B to the centre; ϕ is the angle the joining line makes with the perpendicular on the tangent. It is seen thus that the arc of a hyperbola depends, not only on the integral which gives the arc of an ellipse, but also on $\displaystyle\int_0^\phi \frac{d\phi}{\Delta\phi}$, which is called an elliptic integral of the *first kind*, and denoted by $\text{F}(\kappa, \phi)$, ϕ and κ being called amplitude and modulus as before.

193. When this is applied to the formulæ of Fagnani they become for the ellipse, calling ψ the value which ϕ has for the point F,

$$\sin\psi = \frac{\cos\phi}{\Delta\phi}, \text{ arc AB} - \text{arc GF} = a\kappa^2 \sin\phi \sin\psi = a\kappa^2 \frac{\sin\phi\cos\phi}{\Delta\phi}$$

and it is easily found that the expression on the right is the length on the tangent at either B or F intercepted between the curve and the foot of the central perpendicular let fall upon it.

In application to the hyperbola, similarly,

$$\sin\psi = \frac{\cos\phi}{\Delta\phi}, \text{ and arc AB} + \text{arc AF} = \frac{c\Delta\phi}{\sin\phi\cos\phi} + \text{const.}$$

Now the length of the tangent between the point of contact ϕ and the foot of the central perpendicular upon it is $c\tan\phi\Delta\phi$; hence denoting by E and F the *complete functions* $\text{E}(\kappa, \tfrac{1}{2}\pi)$, $\text{F}(\kappa, \tfrac{1}{2}\pi)$, the value of the constant can be determined;

$$\therefore \quad \frac{\text{arc AB} + \text{arc AF}}{c} = \frac{\Delta\phi}{\sin\phi\cos\phi} + \kappa'^2\text{F} - \text{E};$$

and this value of the constant is the difference between the entire hyperbolic quadrant and the length of the corresponding asymptote.

194. Landen, continuing these investigations in 1775, considers the *hyperbola* whose semi-axes are $a = m - n$ and $b = 2\sqrt{mn}$; then, writing $\text{CP} = \left\{\overline{m-n}^2 - t^2\right\}^{\frac{1}{2}}$ (fig. 17), he notices that

$$\text{DP} - \text{AD} = \int \left\{ \frac{\overline{m-n}^2 - t^2}{\overline{m+n}^2 - t^2} \right\}^{\frac{1}{2}} dt.$$

Then he says it is well known that, in the *ellipse* whose semi-axes are m, n, the arc z from the conjugate axis to the point whose abscissa is x is

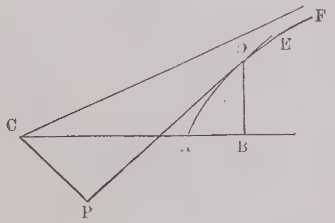

Fig. 17.

$$z = \int \left(\frac{m^2 - gx^2}{m^2 - x^2} \right)^{\frac{1}{2}} dx,$$

where g is

$$\frac{m^2 - n^2}{m^2};$$

and therefore in the *ellipse* whose semi-axes are $m + n$ and $2\sqrt{mn}$, for an abscissa $= \dfrac{m+n}{m-n}t$, the arc $= \displaystyle\int \left(\frac{\overline{m+n}^2 - t^2}{\overline{m-n}^2 - t^2} \right)^{\frac{1}{2}} dt$.

But further, in the ellipse m, n, the length t of the tangent at the point whose abscissa is x, to the foot of the central perpendicular on it, is

$$t = gx\left(\frac{m^2 - x^2}{m^2 - gx^2} \right)^{\frac{1}{2}};$$

whence $2gx^2 = gm^2 + t^2 - \sqrt{(m^2 - n^2)^2 - 2(m^2 + n^2)t^2 + t^4}$. Differentiating this, since

$$z = \int \frac{gxdx}{t}, \quad \therefore 2z = t + \tfrac{1}{2}$$

$$\int \left(\frac{\overline{m+n}^2 - t^2}{\overline{m-n}^2 - t^2} \right)^{\frac{1}{2}} dt + \tfrac{1}{2} \int \left(\frac{\overline{m-n}^2 - t^2}{\overline{m+n}^2 - t^2} \right)^{\frac{1}{2}} dt,$$

which is a relation between the hyperbolic arc, the two elliptic arcs, and a portion of a right line. Landen remarks on his discovery, "Thus, beyond my expectation, I find that the hyperbola may in general be rectified by means of two ellipses,"—a result apparently of secondary importance compared with the method it is attained by, which involves the principle of what after Legendre is known as Landen's transformation.

195. But, simultaneously with the geometrical interest thus developed in these integrals, they also attracted attention to their more algebraic relationships. James Bernoulli (1694) devoted particular attention to the "elastic curve," which is defined by the equation $dx = \pm\frac{y^2dy}{\sqrt{a^4-y^4}}$, with a view to construct it by the quadrature or rectification of a conic. Maclaurin (1742) gave such a construction, depending on the rectification of the equilateral hyperbola; and in like manner constructed by the aid of arcs of conics the integrals of expressions such as

$$\frac{dx}{\sqrt{x}\sqrt{1+x^2}},\ \frac{dx}{(1\mp x^2)^{\frac{3}{4}}},$$

and others like them, which can be reduced to elliptic differentials. D'Alembert (1746) extended these results. His paper in the *History of the Berlin Academy* treats a number of differentials, whose integrals are of the same forms as those by which the arc of an ellipse or hyperbola is expressed. When a differential expression can be reduced to the differential element of the arc of one of these curves, D'Alembert calls this the integration of it by means of an ellipse or hyperbola. This paper is of a purely analytic character, and is penetrated by a tendency to classification of elliptic differentials similar to that which has effected in the works of Legendre such important services in the development of analysis.

196. In the works of Euler, of which from 350 to 400 quarto pages are concerned with this department of our subject, the geometrical and analytical aspects alternate. His first investigations are in the *St. Petersburg Commentaries* (1761), on the integration of the differential equation

$$\frac{mdx}{\sqrt{1-x^4}} = \frac{ndy}{\sqrt{1-y^4}};$$

and it is remarked that the differential equation of a more general form

$$\frac{mdx}{\sqrt{\mathrm{A}+2\mathrm{B}x^2+\mathrm{C}x^4}} = \frac{ndy}{\sqrt{\mathrm{A}+2\mathrm{B}y^2+\mathrm{C}y^4}}$$

can be completely integrated by an algebraic equation, provided the numbers m and n are rational. He extends the same method of integrating to the apparently more general equation

$$\frac{mdx}{\sqrt{\mathrm{A}+2\mathrm{B}x+\mathrm{C}x^2+2\mathrm{D}x^3+\mathrm{E}x^4}} = \frac{ndy}{\sqrt{\mathrm{A}+2\mathrm{B}y+\mathrm{C}y^2+2\mathrm{D}y^3+\mathrm{E}y^4}}.$$

In the next paper in the same volume Euler determines on the quadrant of an ellipse two arcs whose sum can be expressed geometrically, reproducing many of Fagnani's formulæ.

197. Euler's most important investigations are collected in his *Institutiones Calc. Int.*, vol. i. sec. 2, cap. vi. His method, being essentially as follows, has much analogy with Fagnani's, given in § 190.

Let the equation

$$(ax^2+2a'x+a'')y^2+2(bx^2+2b'x+b'')y$$
$$+cx^2+2c'x+c'' = \mathrm{L}y^2+2\mathrm{M}y+\mathrm{N}=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

or

$$(ay^2+2by+c)x^2+2(a'y^2+2b'y+c')x$$
$$+a''y^2+2b''y+c'' = \mathrm{P}x^2+2\mathrm{Q}x+\mathrm{R}=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

subsist between x and y. Differentiating either, we get

$$(\mathrm{P}x+\mathrm{Q})dx+(\mathrm{L}y+\mathrm{M})dy=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Further, by (1, 2)

$$(\mathrm{P}x+\mathrm{Q})^2=\mathrm{Q}^2-\mathrm{PR},\ (\mathrm{L}y+\mathrm{M})^2=\mathrm{M}^2-\mathrm{LN}, \quad . \quad . \quad . \quad (4);$$

taking the roots positive, (3) becomes

$$\frac{dx}{\sqrt{\mathrm{M}^2-\mathrm{LN}}}+\frac{dy}{\sqrt{\mathrm{Q}^2-\mathrm{PR}}}=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

in which the radicals are respectively functions of x and of y expressible from (1) and (2).

If the functions under the radicals are to be severally the same functions of x and y, the following conditions result:—

$$b^2-ac=a'^2-aa'',\quad 2bb'-ac'-a'c=2a'b'-ab''-a''b,$$
$$bb''=a'c',\quad 2b'b''-a'c''-a''c'=2b'c'-bc''-b''c,$$
$$b''^2-a''c''=c'^2-cc''.$$

The values of c and c' being substituted from the first and third equations, in the second we get $a'=b$. Whence first and third give $a''=c$, $b''=c'$; and the others are identical. (1) thus becomes

$$ax^2y^2+2bxy(x+y)+c(x^2+y^2)+4b'xy+2c'(x+y)$$
$$+c''=0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Hence (5) takes the form

$$\frac{dx}{\sqrt{\mathrm{A}+2\mathrm{B}x+\mathrm{C}x^2+2\mathrm{D}x^3+\mathrm{E}x^4}}$$
$$+\frac{dy}{\sqrt{\mathrm{A}+2\mathrm{B}y+\mathrm{C}y^2+2\mathrm{D}y^3+\mathrm{E}y^4}}=0,$$

or more briefly

$$\frac{dx}{\sqrt{\mathrm{X}}}+\frac{dy}{\sqrt{\mathrm{Y}}}=0,$$

of which the obvious transcendental integral is

$$\int\frac{dx}{\sqrt{\mathrm{X}}}+\int\frac{dy}{\sqrt{\mathrm{Y}}}=\text{const.}$$

where $\quad \mathrm{A}=c'^2-cc'',\ \mathrm{B}=2b'c'-bc''-cc'.$

$\mathrm{C}=4b'^2-ac''-c^2-2bc',\ \mathrm{D}=2bb'-ac'-bc,\ \mathrm{E}=b^2-ac.$

Further, from (4)

$$\sqrt{\mathrm{Y}}=(ay^2+2by+c)x+by^2+2b'y+c',$$
$$\sqrt{\mathrm{X}}=(ax^2+2bx+c)y+bx^2+2b'x+c'.$$

Hence $\quad \dfrac{\sqrt{\mathrm{X}}-\sqrt{\mathrm{Y}}}{x-y}=axy+b(x+y)+2b'-c.$

Squaring, we get, by (6), etc., the algebraic integral

$$\left(\frac{\sqrt{\mathrm{X}}-\sqrt{\mathrm{Y}}}{x-y}\right)^2=\mathrm{E}(x+y)^2+2\mathrm{D}(x+y)+(2b'-c)^2-ac''.$$

The constant on the right, involving an arbitrary quantity, if A, B, C, D, E are known, may be taken as the constant of integration.

198. In Euler's first paper in vol. vii. of the *St. Petersburg Commentaries*, he uses the "æquatio canonica" $0=\alpha+\gamma(x^2+y^2)+2\delta xy+\epsilon x^2y^2$ as a starting point for establishing his theorem of addition, and, introducing the notation

$$\Pi(x)=\int_0^x\frac{\mathrm{A}'+\mathrm{B}'x^2+\mathrm{C}'x^4}{\sqrt{\mathrm{A}+\mathrm{C}x^2+\mathrm{E}x^4}}dx,$$

establishes the equation

$$\Pi(x)+\Pi(y)-\Pi(z)=\frac{xyz}{\sqrt{\mathrm{A}}}\left[-\mathrm{B}'-\frac{x^2+y^2+z^2}{2}\mathrm{C}'+\frac{x^2y^2z^2}{6\mathrm{A}}\mathrm{EC}'\right],$$

where $\quad z=\dfrac{x\sqrt{\mathrm{A}(\mathrm{A}+\mathrm{C}y^2+\mathrm{E}y^4)}+y\sqrt{\mathrm{A}(\mathrm{A}+\mathrm{C}x^2+\mathrm{E}x^4)}}{\mathrm{A}-\mathrm{E}x^2y^2}.$

Now, when $\mathrm{B}'=0$, $\mathrm{C}'=0$, these equations represent the theorem of addition for Legendre's first kind of elliptic integrals, and when $\mathrm{A}=1$, $\mathrm{C}=-(1+\kappa^2)$, $\mathrm{E}=\kappa^2$, $\mathrm{A}'=1$, $\mathrm{B}'=-\kappa^2$, $\mathrm{C}'=0$, they become the theorem of addition for his second kind. Thus it appears that already in 1761, Euler was acquainted with this fundamental theorem, of which he gave many applications to the comparison of elliptic arcs.

199. But it seems to have been Euler's paper "De reductione formularum integralium ad rectificationem ellipsis ac hyperbolæ" (*Novi Comment.*, x. p. 3–50, St. Petersburg, 1766), which impelled Legendre to his investigations. With special cases of the general relation, § 197 (1), between x and y, Euler transforms integrals contained in the form $\int\sqrt{\frac{f+gx^2}{k+hx^2}}dx$, and distinguishes whether the integral has one of the five significations, arc of ellipse, arc of hyperbola, or either or both of these along with an algebraic part,—collecting in one general investigation the results of Maclaurin and D'Alembert on the rectification of conics. Here we find the words,—regarding the desirability of a suitable notation by which elliptic arcs may be as conveniently expressed in calculation as logarithms and circular arcs are at present, "such signs," he says, "will afford a new sort of calculus, of which I have here attempted the exposition of the first elements,"—which Legendre cites in the preface to his great work in 1825 as having remained unfulfilled but for his own labors continued till that date from his first publications on the subject in 1786.

200. In vol. iv. of the *Miscellanea Taurinensia*, Lagrange deals with the integration which had been given by Euler, remarking that it was due only to a kind of lucky accident. This indeed Euler himself admitted when he stated that he had not obtained this result by a regular method, but "potius tentando, vel divinando," and recommended mathematicians to seek a direct method. Lagrange here lays down the principle that, when the integral of a differential equation of the first degree cannot be found, the equation should be differentiated; and, combining the re-

sult with the given equation, an integral equation of the first degree different from the proposed may be found. Then by means of these two the first differentials may be eliminated, and the result is the required integral. If this fail we may differentiate once more, and try to get a new equation of the second order, and so on. This enabled him to give a deduction of Euler's equation, which Euler received with the greatest admiration, and gives nearly as follows in his *Institut. Calc. Int.*, iv. p. 466.

Writing for brevity

$$\left.\begin{array}{l} A + Bx + Cx^2 + Dx^3 + Ex^4 = X \\ A + By + Cy^2 + Dy^3 + Ey^4 = Y \end{array}\right\} \quad . \quad . \quad . \quad . \quad (1),$$

suppose the differential equation between x and y to be

$$\frac{dx}{\sqrt{X}} + \frac{dy}{\sqrt{Y}} = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

Regard x and y as functions of a variable t, and replace (2) by the following

$$\frac{dx}{dt} = \sqrt{X}, \ \frac{dy}{dt} = -\sqrt{Y} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Assuming $\qquad x + y = p, \ x - y = q \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$

we get $\dfrac{dp}{dt} = \sqrt{X} - \sqrt{Y}, \ \dfrac{dq}{dt} = \sqrt{X} + \sqrt{Y}, \ \dfrac{d^2p}{dt^2} = \dfrac{X' + Y'}{2}$. (5),

which last is, by (1),

$$\frac{d^2p}{dt^2} = B + C(x + y) + \tfrac{3}{2}D(x^2 + y^2) + 2E(x^3 + y^3) \quad . \quad . \quad (6).$$

We also get, from (5), $\dfrac{dp}{dt}\,\dfrac{dq}{dt} = X - Y$

$$= (x - y)\ \{B + C(x + y) + D(x^2 + xy + y^2) + E(x + y)(x^2 + y^2)\},$$

which, combined with (6), gives, by (4),

$$q\frac{d^2p}{dt^2} - \frac{dp}{dt}\,\frac{dq}{dt} = q^3(\tfrac{1}{2}D + Ep), \ i.e., \frac{2}{q}\,\frac{d}{dt}\left(\frac{1}{q}\,\frac{dp}{dt}\right) \\ = D + 2Ep.$$

Multiplying by $\dfrac{dp}{dt}$, this gives on integration, with F a constant

$$\left(\frac{1}{q}\,\frac{dp}{dt}\right)^2 = Dp + Ep^2 + F;$$

whence, replacing values,

$$\left(\frac{\sqrt{X} - \sqrt{Y}}{x - y}\right)^2 = D(x + y) + E(x + y)^2 + F,$$

which is the same result as Euler's (§ 197).

A principal advantage of this method consists in its admitting of generalization, which Euler's method, depending on the solution of a quadratic equation, excludes. But Lagrange fails to apply it to the case of X and Y being arbitrary polynomials respectively in x and y; all assumptions lead back to the forms of X and Y in (1).

201. In a paper of Euler's in the *St. Petersburg Transactions* for 1771, an angle is introduced as the variable into the integral for the arc of an ellipse. In another paper, in the *Novi Commentarii*, 1767, he had also remarked that, in a differential such as

$$\frac{dx}{\sqrt{A + Bx + Cx^2 + Dx^3 + Ex^4}},$$

by a substitution of the form $x = \dfrac{mz + a}{nz + b}$ the odd powers of z under the radical can be abolished; and by a like substitution, removing the odd powers of y, Euler treats, without any loss of generality, the differential equation in the form

$$\frac{dx}{\sqrt{A + Cx^2 + Ex^4}} = \frac{dy}{\sqrt{A + Cy^2 + Ey^4}}.$$

This furnishes an essential simplification of the process of calculation, and leads to the results of his important and remarkable "Plenior Explicatio" in the *St. Petersburg Transactions* for 1781. This contains in fact a proposition which includes the theorem of addition for all three kinds of elliptic integrals of Legendre.

202. Putting $\qquad \Pi(z) = \displaystyle\int_0^z \frac{Zdz}{\sqrt{1 + mz^2 + nz^4}},$

where Z is an even function of z, $\Pi(x) + \Pi(y) - \Pi(z)$ can be exhibited as an algebraic function of x, y, and z, provided a certain algebraic relation holds between x, y, and z. "But now," observes Euler, "I have noticed that the same comparisons may be instituted if for Z be assumed any rational function of z^2, as suppose one of the form

$$\frac{F + Gz^2 + Hz^4 + Iz^6 + Kz^8 +}{f + gz^2 + hz^4 + iz^6 + kz^8 +};$$

in this case, however, the difference between the sum of two such formulæ and a third is no longer found to be an algebraic quantity, but can always be expressed by logarithms and circular arcs, so that the investigation is much more extensive than I hitherto conceived."

To establish this, assume

$$x^2 + y^2 - z^2 + 2xy\sqrt{1 + mz^2 + nz^4} - nx^2y^2z^2 = 0 \quad . \quad . \quad . \quad (1),$$

or, writing $\qquad \sqrt{1 + mz^2 + nz^4} = \Delta \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$

$$x^2 + y^2 - z^2 + 2xy\Delta - nx^2y^2z^2 = 0 \quad . \quad . \quad . \quad . \quad . \quad (3).$$

Solving in turn for x and y, this gives

$$\left.\begin{array}{l} x(1 - ny^2z^2) + y\Delta = z\sqrt{1 + my^2 + ny^4} \\ y(1 - nx^2z^2) + x\Delta = z\sqrt{1 + mx^2 + nx^4} \end{array}\right\} \quad . \quad . \quad . \quad (4).$$

But, by differentiation, we know that

$$\frac{dx}{\sqrt{1 + mx^2 + nx^4}} + \frac{dy}{\sqrt{1 + my^2 + ny^4}} = 0 \quad . \quad . \quad . \quad (5),$$

which may be written thus

$$\frac{dx}{y(1 - nx^2z^2) + x\Delta} = -\frac{dy}{x(1 - ny^2z^2) + y\Delta} \quad . \quad . \quad . \quad . \quad (6).$$

For $x = 0$, the relation (3) gives $y = z$; whence (5) integrated gives the known theorem of addition for integrals of the first kind.

Now let X, Y be the same functions of x^2, y^2 as Z is of z^2; then writing

$$\frac{Xdx}{\sqrt{1 + mx^2 + nx^4}} + \frac{Ydy}{\sqrt{1 + my^2 + ny^4}} = dV \quad . \quad . \quad . \quad . \quad . \quad . \quad (7),$$

the quantity V may be found as follows.

We can eliminate by (5) either dx or dy from (7); but, as there is no reason to consider V as a function of x or of y specially, introduce a new independent variable $u = xy$. Then we may replace (6) by

$$\left.\begin{array}{l} dx = [y(1 - nx^2z^2) + x\Delta]sdu, \\ dy = -[x(1 - ny^2z^2) + y\Delta]sdu \end{array}\right\} \quad . \quad . \quad . \quad . \quad . \quad (8),$$

where we take $\qquad s = \dfrac{1}{y^2 - x^2}.$

Thus $\qquad \dfrac{dx}{\sqrt{1 + mx^2 + nx^4}} = -\dfrac{dy}{\sqrt{1 + my^2 + ny^4}} = \dfrac{zdu}{y^2 - x^2},$

which give $\qquad dV = -z\dfrac{Y - X}{y^2 - x^2}du \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$

But now $\dfrac{Y - X}{y^2 - x^2}$ is a function of xy and $x^2 + y^2$, or of u, since by (3)

$$x^2 + y^2 = z^2 - 2u\Delta + nu^2z^2.$$

Thus, putting $z\dfrac{Y - X}{y^2 - x^2} = U$, we have $dV = -Udu$. Substituting this in (7), and integrating, we have

$$\Pi(x) + \Pi(y) - \Pi(z) = -\int_0^u Udu,$$

since, for $x = 0$, $y = z$ and $u = 0$.

As an example,

if $\ Z = \dfrac{a + bz^2}{a' + b'z^2}$, then $\dfrac{Y - X}{y^2 - x^2} = \dfrac{a'b - ab'}{a'^2 + a'b'(x^2 + y^2) + b'^2x^2y^2}$;

that is, $\qquad U = \dfrac{(a'b - ab')z}{a'^2 + a'b'z^2 + 2a'b'\Delta u + (b'^2 + a'b'nz^2)u^2}.$

Thus, if we take

$$\Pi(z) = \int_0^z \frac{a + bz^2}{a' + b'z^2}\,\frac{dz}{\sqrt{1 + mz^2 + nz^4}},$$

we have

$$\Pi(x) + \Pi(y) - \Pi(z)$$

$$= \int_0^u \frac{(ab' - a'b)z\,du}{a'^2 + a'b'z^2 + 2a'b'\Delta u + (b'^2 + a'b'nz^2, u^2},$$

in which after integration u is to be put $= xy$. By assigning special values to the constants this equation can be applied to each kind of elliptic integral.

203. In the *Théorie des Fonctions Analytiques* of Lagrange there is found the remark on the relation between the summation of elliptic integrals and spherical triangles which is involved in the formulæ of § 200, and of which we have given the essential formulæ in §§ 34–36. But Lagrange's paper "On a new method of the Integral Calculus for Differentials affected with the square root of a polynomial of not more than the fourth degree" (*Mémoire de l'Acad. des Sciences*, 1784–85, 2d part, Turin, 1786), contains additions of much greater importance to our subject.

Taking

$$p' = p + \sqrt{p^2 - q^2}, \qquad q' = p - \sqrt{p^2 - q^2},$$

$$p'' = p' + \sqrt{p'^2 - q'^2}, \qquad q'' = p' - \sqrt{p'^2 - q'^2},$$

$$p''' = p'' + \sqrt{p''^2 - q''^2}, \quad q''' = p'' - \sqrt{p''^2 - q''^2}.$$

$$\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot$$

Further, writing for brevity,

$$R = \sqrt{(1 \pm p^2y^2)(1 \pm q^2y^2)},$$

$$R' = \sqrt{(1 \pm p'^2y'^2)(1 \pm q'^2y'^2)},$$

$$R'' = \sqrt{(1 \pm p''^2y''^2)(1 \pm q''^2y''^2)};$$

$$\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot$$

and

$$y' = \frac{yR}{1 \pm q^2y^2}, \quad y'' = \frac{y'R'}{1 \pm q'^2y'^2}, \quad y''' = \frac{y''R''}{1 \pm q''^2y''^2} \cdots$$

we have the equations

$$y^2 = \frac{\pm q^2y'^2 - 1 + R'}{\pm 2p^2},$$

$$y'^2 = \frac{\pm q'^2y''^2 - 1 + R''}{\pm 2p'^2},$$

$$y''^2 = \frac{\pm q''^2y''^2 - 1 + R'''}{\pm 2p''^2};$$

$$\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot$$

and

$$\frac{dy}{R} = \frac{dy'}{R'} = \frac{dy''}{R''} \cdots$$

Now, assuming $q < p$, we have $p < p' < p''$, and, as $q' = q \cdot \frac{q}{p'}$, $q > q' > q''$, etc., without limit.

Lagrange gives another system of equations of reduction following from the above series when continued backwards, so that the series are

$$\ldots\ p_2,\ p_1,\ p,\ p',\ p''\ \ldots$$

$$\ldots\ q_2,\ q_1,\ q,\ q',\ q''\ \ldots$$

The equations

$$p = p_1 + \sqrt{p_1^2 - q_1^2}, \quad q = p_1 - \sqrt{p_1^2 - q_1^2},$$

$$p_1 = p_2 + \sqrt{p_2^2 - q_2^2}, \quad q_1 = p_2 - \sqrt{p_2^2 - q_2^2},$$

$$\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot$$

give conversely

$$p_1 = \tfrac{1}{2}(p + q), \quad q_1 = \sqrt{pq},$$

$$p_2 = \tfrac{1}{2}(p_1 + q_1), \quad q_2 = \sqrt{p_1q_1},$$

$$\cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot \quad \cdot$$

and the terms $p, p_1, p_2 \ldots$ decrease, while $q, q_1, q_2 \ldots$ increase.

Now, putting

$$y = \frac{y_1R_1}{1 \pm q_1^2y_1^2}, \quad y_1 = \frac{y_2R_2}{1 \pm q_2^2y_2^2}, \cdots$$

$$R_1 = \sqrt{(1 \pm p_1^2y_1^2)(1 \pm q_1^2y_1^2)},$$

$$R_2 = \sqrt{(1 \pm p_2^2y_2^2)(1 \pm q_2^2y_2^2)}, \ \ldots$$

we get

$$y_1^2 = \frac{\pm q_1^2y^2 - 1 + R}{\pm 2p_1^2}, \text{ etc., and } \frac{dy}{R} = \frac{dy_1}{R_1} = \frac{dy_2}{R^2} = \text{etc.}$$

The former series are essentially the transformation known by Landen's name; the latter, indirectly, are (§ 214) the transformation which Gauss published in 1818, and on which his theory of the arithmetico-geometric mean is based.

204. We have thus glanced at the most important contributions to this branch of our subject previous to Legendre. His "Mémoire sur les intégrations par d'arcs d'ellipse" (*Histoire de l'Acad.*, 1786) appeared a few years after Euler's death (1783). The geometric basis is here almost abandoned. Establishing with ease and elegance the theorems of Fagnani, Landen, and Euler, there are perceptible traces of a coming theory of transformation in the analytical conception of these theorems. Legendre's *Mémoire sur les Transcendantes Elliptiques* (Paris, 1793) contains the division of elliptic integrals into their different kinds, the reduction of integrals of each kind to the simplest normal forms, and the calculation of elliptic integrals by most accurate modes of approximation. All these investigations are collected in Legendre's *Exercices* (Paris, 1811–19), and later in his *Traité des Fonctions elliptiques et des Intégrales Eulériennes* (Paris, 1825–6, 2 vols., suppl. vol., 1828).

205. "It is Legendre's undying glory," said Lejeune Dirichlet of this great work, "to have recognized in the discoveries we have just mentioned (of Fagnani, Euler, Landen, and Lagrange) the budding of a mighty branch of analysis, and by the toil of half a life to have erected on these bases an independent theory which embraces all integrals containing no other irrationality but a square root under which the variable rises only to the fourth degree. Euler had already noticed with what modifications his theorem can be extended to such integrals; Legendre, starting from the happy thought of reducing all these integrals to fixed canonical forms, attained the knowledge, so important for the development of the theory, that they group into three essentially different kinds. Submitting then each kind to a careful investigation, he discovered many of their most important properties, of which chiefly those which belong to the third kind were very obscure and inaccessible. Only for the most persistent tenacity, which ever anew led the great mathematician to his subject, did the victory at last declare itself over difficulties apparently insurmountable by the weapons at his disposal."

206. Having shown that the integral $\int \frac{P\,dx}{R}$, where P is a rational function of x, and $R = (\alpha + \beta x + \gamma x^2 + \delta x^3 + \epsilon x^4)^{\frac{1}{2}}$, can be reduced to the fixed fundamental forms $\int \frac{dx}{R}$, $\int \frac{x\,dx}{R}$, $\int \frac{x^2dx}{R}$, $\int \frac{dx}{(1 + nx)R}$, Legendre removes, by aid of the linear transformation $x = \frac{p + qy}{1 + y}$, the odd powers of the variable from the polynomial R^2, and shows, by enumeration of cases, that $\frac{dx}{R}$ can always be reduced to the form $\frac{m\,d\phi}{\sqrt{1 - c^2 \sin^2\phi}}$, where c is a quantity less than unity. Thus he reduces the general elliptic integral $\int \frac{Q\,d\phi}{\sqrt{1 - c^2 \sin^2\phi}}$, with abstraction from an algebraic part, to the three normal forms of "elliptic functions or transcendents"—

$$\int \frac{d\phi}{\Delta} = F, \int \Delta\,d\phi = E, \int \frac{d\phi}{(1 + n \sin^2\phi)\Delta} = \Pi,$$

Δ being an abbreviation for the radical $\sqrt{1 - c^2 \sin^2\phi}$.

With this reduction to fixed normal forms the foundation of the theory of elliptic integrals is laid, and the essentially irreducible integrals found which belong to a square root of a biquadratic function. The same reduction subsequently led to the division of the general Abelian integrals into those of the first, second, and third kinds, in accordance with the properties of these three classes of integrals, either of remaining always finite, or of becoming infinite, algebraically only at infinity, or logarithmically at two different points.

It will be perceived that the epithet "elliptic" applied to these integrals is purely conventional, arising from the connection of one of them with the arc of an ellipse; but even at this stage it is apparent that we are concerned with matters of much greater generality than the name indicates. It may also be noticed that, though Legendre calls by the name elliptic functions what are now called elliptic integrals, this is a change introduced by Jacobi, which Legendre long resisted. The change consists in regarding the superior limit of the integral of the first kind as a function of the integral, the latter being now considered as the independent variable. Expressed in symbols the change is that, in Legendre's equation $F(\kappa,\phi)=\int_0^\phi \frac{d\phi}{\Delta(\kappa,\phi)}=u$, Jacobi calls $\phi=\text{am}(u,\kappa)$, and $\sin\phi$, $\cos\phi$, or $\Delta\phi$, etc. (or, in this notation, $\sin \text{am}\, u$, $\cos \text{am}\, u$, $\Delta\text{am}\, u$, etc.), are his elliptic functions.

207. Legendre proceeds, after classifying the integrals, to the comparison of his elliptic functions of the first kind. All geometers, he says, are acquainted with the complete algebraic integral given by Euler of the differential equation

$$\frac{dx}{(\alpha+\beta x+\gamma x^2+\delta x^3+\epsilon x^4)^{\frac{1}{2}}}=\frac{dy}{(\alpha+\beta y+\gamma y^2+\delta y^3+\epsilon y^4)^{\frac{1}{2}}}=0;$$

the discovery of which, in the introduction, he too ascribes to a combination of good fortune "quoique ces hazards n'arrivent qu'à ceux qui savent les faire naître." Our reductions show that this equation can, without loss of generality, be put under the form

$$\frac{d\phi}{\sqrt{1-c^2\sin^2\phi}}+\frac{d\psi}{\sqrt{1-c^2\sin^2\psi}}=0;$$

and then its integral is

$$F(\phi)+F(\psi)=F(\mu),$$

μ being an arbitrary constant. But the integral found by Euler's method is thus written

$$\cos\phi\cos\psi-\sin\phi\sin\psi\sqrt{1-c^2\sin^2\mu}=\cos\mu,$$

which he then verifies *a posteriori.*

The expression $\sin\mu=\dfrac{\sin\phi\cos\psi\,\Delta\psi+\sin\psi\cos\phi\,\Delta\phi}{1-c^2\sin^2\phi\sin^2\psi}$,

$$\cos\mu=\frac{\cos\phi\cos\psi-\sin\phi\sin\psi\,\Delta\phi\,\Delta\psi}{1-c^2\sin^2\phi\sin^2\psi},$$

$$\Delta\mu=\frac{\Delta\phi\Delta\psi-c^2\sin\phi\sin\psi\cos\phi\cos\psi}{1-c^2\sin^2\phi\sin^2\psi},$$

are at once derived from this form of the integral; and the corresponding formulæ for the amplitude of the difference between two functions follow by replacing ψ by $-\psi$.

Legendre next proceeds to the formulæ for finding algebraically a multiple function of a given one, connecting the angles ϕ_{n-1}, ϕ_n, ϕ_{n+1}, by the relations equivalent to $F(\phi_{n+1})=F(\phi_n)+F(\phi)$, $F(\phi_{n-1})=F(\phi_n)-F(\phi)$, which he writes

$$\sin\phi_{n+1}+\sin\phi_{n-1}=\frac{2\Delta\cos\phi\,.\,\sin\phi_n}{1-c^2\sin^2\phi\sin^2\phi_n},$$

$$\cos\phi_{n+1}+\cos\phi_{n-1}=\frac{2\cos\phi\,.\,\cos\phi_n}{1-c^2\sin^2\phi\sin^2\phi_n}.$$

These can be applied in succession. Investigating the division of a function into n equal parts the equation is found to rise in general to the degree n^2; but for the complete function the equation is only of the degree $\frac{1}{2}(n^2-1)$ when n is odd.

208. Proceeding to generalization of Euler's addition theorem, Legendre admits that, denoting the radical by $R(x)$, etc., the equation $0=\frac{mdx}{R(x)}+\frac{ndy}{R(y)}+\frac{pdz}{R(z)}+$ etc., can for integer values of m, n, p always be expressed in the form $F(\mu)=mF(\phi)+nF(\psi)+$ etc., and so will always have a complete algebraic integral, for nothing prevents the supposition that z and the following variables are given algebraic functions of x and y. Perhaps, he says, this is the only way of generalizing Euler's result concerning the equation $\frac{dx}{R(x)}+\frac{dy}{R(y)}=0$. For, though Lagrange tried to find cases of integrability of $\frac{dx}{\sqrt{X}}+\frac{dy}{\sqrt{Y}}$, without supposing the two polynomials X and Y entirely similar, it does not seem that he arrived at any other result; the equation he gives (*Mém. de Turin*, iv. 119) is immediately reducible to Euler's. Thus, as has been remarked, Legendre was at this time very far from anticipating the very general transformations, since discovered, or the celebrated theorem of Abel which so marvellously extended this subject.

209. Having illustrated the functions F by the lemniscate and other curves, algebraic and transcendent, whose arcs are expressed by functions of the first kind, as well as by the expression for the time in the motion of a simple pendulum, Legendre enters, in chapter ix., on the comparison of elliptic functions of the second kind. Corresponding to the relation $F(\phi)+F(\psi)-F(\mu)=0$, these functions are related by

$$E(\phi)+E(\psi)-E(\mu)=c^2\sin\mu\sin\phi\sin\psi.$$

This includes Fagnani's as a particular case, and of course there is a similar relation for comparison of the arcs of hyperbolæ. In chap. xii. the well-known relation of Legendre is established between complete integrals of the first two kinds with complementary moduli; b and c being moduli are said to be complementary when $b^2+c^2=1$. Denoting by F, E the values of $F\left(\frac{\pi}{2}, c\right)$, $E\left(\frac{\pi}{2}, c\right)$, and by F′, E′ those of $F\left(\frac{\pi}{2}, b\right)$, $E\left(\frac{\pi}{2}, b\right)$, this relation, which has been already demonstrated, § 183, is

$$FE'+F'E-FF'=\frac{\pi}{2}.$$

These complete functions satisfy differential equations of the second order, viz., F satisfies

$$(1-c^2)\frac{d^2F}{dc^2}+\frac{1-3c^2}{c}\frac{dF}{dc}-F=0,$$

and the complete E

$$(1-c^2)\frac{d^2E}{dc^2}+\frac{1-c^2}{c}\frac{dE}{dc}+E=0,$$

with corresponding equations when b is taken as the independent variable. The complete integrals of these differential equations are assigned in terms of both sets of complete functions, and the differential equations are utilized to show the law of the development of these functions in series of powers of the complement of the modulus, since when the modulus is near unity the ordinary series in powers of the modulus do not sufficiently converge.

210. In treating integrals of the *third kind*, the presence of a third determining magnitude, the *parameter n*, besides the amplitude ϕ and modulus c, which are common to the first two kinds, is an additional complication. Legendre first establishes the relation

$$\Pi(n)+\Pi\left(\frac{c^2}{n}\right)=F+\frac{1}{\sqrt{\alpha}}\tan^{-1}\frac{\sqrt{\alpha}\tan\phi}{\Delta},$$

where $$\alpha=(1+n)\left(1+\frac{c^2}{n}\right);$$

by means of which any function Π having a parameter greater than c is reduced to depend on one having a parameter less than c, but with the same amplitude and modulus. The quantity α, however, may have different values, and thus the following cases are to be distinguished.

When α is positive (either n positive, or if negative its value is between -1 and $-c^2$) the function introduced is *circular*, as written above.

When α is negative, n is negative, and either greater than -1 or less than $-c^2$, and the function is *logarithmic.* In this case writing $\alpha=-\beta$, the comparison written above is

$$\Pi(n)+\Pi\left(\frac{c^2}{n}\right)=F+\frac{1}{2\sqrt{\beta}}\log\left(\frac{\Delta+\sqrt{\beta}\tan\phi}{\Delta-\sqrt{\beta}\tan\phi}\right).$$

When $\alpha=0$ the integrals are expressed by the first and second kinds.

Omitting the case of $n=-\text{cosec}^2\theta$, which can be reduced to that of $n=-c^2\sin^2\theta$, this case and those of $n=\cot^2\theta$ and $n=-1+b^2\sin^2\theta$ remain, the first being the logarithmic parameter. The other two cases are easily shown to be connected by the relation

$$\frac{1+n}{n}\Pi(n)-\frac{1-m}{m}\Pi(-m)=\frac{c^2F}{mn}$$
$$+\frac{1}{\sqrt{mn}}\tan^{-1}\frac{\sqrt{mn}\,.\sin\phi\cos\phi}{\Delta},$$

provided $(1+n)(1-m)=b^2$, and so constitute really but one case. Functions with imaginary parameters always reduce to others with real parameters of the above two distinct kinds.

211. Comparison of integrals of the third kind by means of the addition theorem leads to the formula

$$\Pi(\phi)+\Pi(\psi)-\Pi(\mu)$$
$$=\frac{1}{\sqrt{\alpha}}\tan^{-1}\left\{\frac{n\sqrt{\alpha}\sin\mu\sin\phi\sin\psi}{1+n-n\cos\mu\cos\phi\cos\psi}\right\};$$

and thus the difference, which is zero in the first kind, and is algebraic in the second, is here expressed by the arc of a circle; which becomes a logarithm if α be negative. Thus finally Legendre remarks that if

$$Z(x) = \int \frac{Pdx}{\sqrt{(\alpha + \beta x + \gamma x^2 + \delta x^3 + \epsilon x^4)}},$$

where P is a rational function of x, there can always be found an algebraic equation between x, y, z, etc., such that the quantity

$$iZ(x) + kZ(y) + lZ(z) + \text{etc.},$$

where i, k, l, etc., are integers, may be determinable by arcs of circles and by logarithms.

212. Legendre next proceeds to the discovery of Landen, having so far been employed mainly with those of Euler. He expresses astonishment that among the many analytic transformations employed by Maclaurin and D'Alembert they had not fallen in with the transformation which brings to light the numerous properties of the chain of moduli, and that this discovery was reserved for Landen, who, however, made but a poor use of it, not even seeing that it furnished a very simple method for approximate calculation of the arcs of conics. It is less astonishing that Euler missed this discovery considering that the beautiful integration which is due to him led him to compare together the different values of the same transcendent, just as arcs of the same curve are compared. But nowhere in his *Mémoires* do we find him varying the constants or parameters of the functions, and thus passing from one curve to another, as is done in comparisons which depend on the scale of moduli. From the fact that Euler has written nothing about the memoir of Landen, Legendre concludes he had never been acquainted with it.

213. The formula given in § 194, by introducing the eccentric angles from the axis minor in the two ellipses, easily gives rise to the equation $\sin\phi^0 = (1+b)\dfrac{\sin\phi\cos\phi}{\Delta}$, where $b = \dfrac{n}{m}$, and so $c = \sqrt{g}$ of that article. ϕ^0 belongs to another ellipse, and for it the value of the corresponding modulus is evidently $\dfrac{1-b}{1+b}$. Legendre sees through the simple proposition of Landen, expressing the arc of a hyperbola by two arcs of ellipses, to the infinite series of moduli which can be produced by repeated application of this substitution. Commencing with functions of the first kind, he shows that $F(c,\phi)$ and $F(c',\phi')$, when $c' = \dfrac{2\sqrt{c}}{1+c}$, and ϕ' is determined by $\sin(2\phi' - \phi) = c\sin\phi$, are related by the equation

$$F(c', \phi') = \frac{1+c}{2}F(c,\phi).$$

Thus, as $2\phi' - \phi$ is always contained between $+\theta$ and $-\theta$, θ being the least arc having c for its sine, there is no ambiguity in determining the values of ϕ' and ϕ. The relation for complete functions is $F^1(c') = (1+c)F^1(c)$. Now conceive an infinite series of increasing moduli

$$c' = \frac{2\sqrt{c}}{1+c}, \quad c'' = \frac{2\sqrt{c'}}{1+c'}, \quad c''' = \frac{2\sqrt{c''}}{1+c''}, \text{ etc.},$$

it will soon attain the limit unity. Forming the complements b', b'', etc., of these moduli, the series decreases continually, and each term is according to the law,

$$b' = \frac{1-c}{1+c}, \quad b'' = \frac{1-c'}{1+c'}, \quad b''' = \frac{1-c''}{1+c''}, \text{ etc.}$$

The series of amplitudes is deduced in succession by the formulæ

$$\sin(2\phi' - \phi) = c\sin\phi,\ \sin(2\phi'' - \phi') = c'\sin\phi',$$
$$\sin(2\phi''' - \phi'') = c''\sin\phi'', \text{ etc.};$$

and so a series of integrals of the first kind is got, related as follows

$$F(c', \phi') = \frac{1+c}{2}F(c,\phi),$$

$$F(c'', \phi'') = \frac{1+c'}{2}F(c', \phi') = \frac{1+c}{2}\,\frac{1+c'}{2}F(c, \phi), \text{ etc.},$$

any two of the functions being always in a ratio independent of the values of the corresponding amplitudes. Similarly for the complete functions

$$F^1(c') = (1+c)F^1(c),\ F^1(c'') = (1+c')F^1(c')$$
$$= (1+c)(1+c')F^1(c), \text{ etc.}$$

But the series, c, c', c'', increasing in one direction, can be prolonged indefinitely in the opposite or decreasing sense to the limit zero. Here the law of terms is

$$c = \frac{2\sqrt{c^0}}{1+c^0}, \quad c^0 = \frac{2\sqrt{c^{00}}}{1+c^{00}}, \quad c^{00} = \frac{2\sqrt{c^{000}}}{1+c^{000}}, \text{ etc.};$$

and similarly

$$c^0 = \frac{1-b}{1+b}, \quad c^{00} = \frac{1-b^0}{1+b^0}, \text{ etc.},$$

with the series of relations of amplitudes derived from $\sin(2\phi - \phi^0) = c^0\sin\phi^0$, etc., which may be written $\tan(\phi^0 - \phi) = b\tan\phi$, etc., and of integrals $F(c, \phi) = \dfrac{1+c^0}{2}F(c^0, \phi^0)$, etc.; or, reversing, since $1 + c^0 = \dfrac{2}{1+b}$,

$$F(c^0, \phi^0) = (1+b)F(c, \phi),$$
$$F(c^{00}, \phi^{00}) = (1+b^0)F(c^0, \phi^0) = (1+b)(1+b^0)F(c, \phi), \text{ etc.},$$

and, for the complete integrals,

$$F^1(c^0) = \frac{1+b}{2}F^1(c),$$

$$F^1(c^{00}) = \frac{1+b^0}{2}F^1(c^0) = \frac{1+b}{2}\,\frac{1+b^0}{2}F^1(c), \text{ etc.},$$

for the decreasing scale of moduli.

214. Now if this be applied to the second kind of integrals we find

$$b^2F(c, \phi) = 2E(c, \phi) - 2(1+c)E(c', \phi') + 2c\sin\phi,$$

showing that an integral of the first kind can be expressed by the aid of two arcs of ellipses, $E(c, \phi)$ and $E(c', \phi')$. Whence by the formula of § 192 it follows that an arc of a hyperbola can always be expressed by two elliptic arcs, the theorem Landen enriched geometry by. Also, by eliminating the integral of the first kind by means of two consecutive equations in the series, the relation between the arcs of three consecutive ellipses in the series can be found; so that by the indefinite rectification of two ellipses in the series

$$\ldots\ E(c'', \phi''),\ E(c', \phi'),\ E(c, \phi),\ E(c^0, \phi^0),\ E(c^{00}, \phi^{00}),\ \ldots$$

of which the extremes are the ellipse having an eccentricity 1, which is a portion of the axis major, and that having an eccentricity 0, which is a circle, the rectification of all the rest is obtained.

The transformations of Lagrange, or of Gauss (§ 203), may be seen to be essentially the same as this of Landen (or Legendre), for by taking $\sin\phi = \dfrac{(1+k)\sin\psi}{1+k\sin^2\psi}$ in $F(c, \phi)$ we get

$$\frac{d\phi}{\sqrt{1-c^2\sin^2\phi}} = \frac{(1+k)d\psi}{\sqrt{1-k^2\sin^2\psi}}, \text{ where } c = \frac{2\sqrt{k}}{1+k}, \text{ or } k = c^0.$$

Hence $\qquad F(c, \phi) = (1+c^0)F(c^0,\psi).$

Now with $F(c^0,\psi) = \frac{1}{2}F(c^0,\phi^0)$, $F(c, \phi) = \dfrac{1+c^0}{2}F(c^0,\phi^0)$, and by eliminating the quantity ψ between the equations $\sin\phi = \dfrac{(1+c^0)\sin\psi}{1+c^0\sin^2\psi}$, $\tan\frac{1}{2}\phi^0 = \tan\psi\sqrt{1-c^{02}\sin^2\psi}$, we obtain the relation given above, $\sin(2\phi - \phi^0) = c^0\sin\phi^0$.

215. This principle of transformation is next applied to the approximate calculation of the three kinds of integrals. Required, for instance, an approximate value of $F(c, \phi)$; the decreasing moduli $c^0, c^{00}, c^{000}, \ldots$ must be calculated, and the increasing amplitudes $\phi^0, \phi^{00}, \phi^{000}, \ldots$ thus

$$F(c, \phi) = \frac{1+c^0}{2}F(c^0, \phi^0) = \frac{1+c^0}{2}\,\frac{1+c^{00}}{2}F(c^{00}, \phi^{00}) = \text{etc.};$$

but, when the modulus has become very small, $\Delta = 1$, and $\displaystyle\int\frac{d\phi}{\Delta} = \phi$; if then Φ be the limit of the angles $\frac{1}{2}\phi^0$, $\frac{1}{4}\phi^{00}$, $\frac{1}{8}\phi^{000}$, etc., we have

$$F(c, \phi) = \Phi(1+c^0)(1+c^{00})\ldots$$

when $\phi = \frac{1}{2}\pi$ the limit Φ will be equally $\frac{1}{2}\pi$; so that the complete function is

$$F^1(c) = \tfrac{1}{2}\pi(1+c^0)(1+c^{00})(1+c^{000})\ldots$$

The continued product which multiplies $\frac{1}{2}\pi$, or Φ, may also be written in a form suited to logarithmic calculation, as

$$\sqrt{\frac{b^0 b^{00} b^{000}}{b}\cdots}$$

The moduli are best got by taking auxiliary angles: let $\sin\mu = c$,

$$\therefore\ c^0 = \tan^2\tfrac{1}{2}\mu, \text{ similarly if } c^0 = \sin\mu^0,\ c^{00} = \tan^2\tfrac{1}{2}\mu^0, \text{ etc.};$$

and when a very small c has been arrived at, we can get the next by

$$c^0 = \tfrac{1}{4}c^2 + \tfrac{1}{4}\cdot\tfrac{3}{6}c^4 + \tfrac{1}{4}\cdot\tfrac{3}{6}\cdot\tfrac{5}{8}c^6 + \ldots$$

Also the angles ϕ^0, ϕ^{00}, are best found by $\tan(\phi^0 - \phi) = b\tan\phi$,—taking for $\phi^0 - \phi$ not always the least angle given by the tables but that which is nearest ϕ.

216. Combining the equation $\Pi = \int\frac{d\phi}{(1 + n\sin^2\phi)\Delta\phi}$ with that derived from it by differentiation with regard to n, and using α to denote $(1+n)\left(1+\frac{c^2}{n}\right)$, as in § 210, it is easily found that

$$2\sqrt{\alpha}.\ \Pi = \Delta\sin\phi\cos\phi\int\frac{dn}{(1+n\sin^2\phi)\sqrt{\alpha}} - c^2\mathrm{F}\int\frac{dn}{n^2\sqrt{\alpha}}$$

$$-(\mathrm{F}-\mathrm{E})\int\frac{dn}{n\sqrt{\alpha}}.$$

Applying this to the case $n = \cot^2\theta$, and writing for brevity $\cot^2\phi = n'$, the following relation is found:—

$$\frac{\Delta(b,\theta)}{\sin\theta\cos\theta}\Pi(n, c, \phi) + \frac{\Delta(c,\phi)}{\sin\phi\cos\phi}\Pi(n', b, \theta)$$

$$= \tfrac{1}{2}\pi + \tan\theta\Delta(b, \theta)\mathrm{F}(c, \phi) + \tan\phi\Delta(c, \phi)\mathrm{F}(b, \theta)$$

$$+ \mathrm{F}(c, \phi)\mathrm{F}(b, \theta) - \mathrm{F}(c, \phi)\mathrm{E}(b, \theta) - \mathrm{E}(c, \phi)\mathrm{F}(b, \theta).$$

Making $\phi = \frac{1}{2}\pi$, this gives for the complete function of the third kind, with positive parameter, the following expression:

$$\frac{\Delta(b,\theta)}{\sin\theta\cos\theta}\Pi^1(n, c) = \tfrac{1}{2}\pi + \tan\theta\Delta(b, \theta)\mathrm{F}^1(c)$$

$$+ \mathrm{F}^1(c)\mathrm{F}(b, \theta) - \mathrm{F}^1(c)\mathrm{E}(b, \theta) - \mathrm{E}^1(c)\mathrm{F}(b, \theta).$$

A similar relation is established for the other cases of the parameter, and in each the complete integral is likewise expressed by integrals of lower kinds.

There now follow the general reduction of integrals with imaginary parameter, and the reduction to elliptic integrals of integrals not included in the general type, as for instance

$$\int\frac{dz}{(1+pz^2)(1+qz^2)^{\frac{1}{3}}},\ \int\frac{d\phi}{(1-c^2\sin^2\phi)^{\frac{1}{4}}},$$

$$\int\frac{d\phi}{(1-c^2\sin^2\phi)^{\frac{1}{3}}},\ \text{etc.}$$

217. In his preface, however, Legendre had directed attention to the discovery of a new scale of moduli, different from that hitherto known, as the most novel of the results distinguishing this work from his *Exercices*. This transformation starts from the assumption

$$\sin\omega = \frac{\sin\phi(m + h\sin^2\phi)}{1 + k\sin^2\phi};$$

and by the conditions that ω and ϕ reach $\frac{1}{2}\pi$ together, and, moreover, that $\cos\omega$ does not contain any other irrational factor in $\sin\phi$ but $\cos\phi$, we get

$$\cos\omega = \frac{\cos\phi(1 - h\sin^2\phi)}{1 + k\sin^2\phi},$$

$$\text{with } k = \tfrac{1}{4}(m-1)(m+3),\ h = \tfrac{1}{4}(m-1)^2.$$

Now $$d\omega = \frac{d\phi(m - k\sin^2\phi)}{1 + k\sin^2\phi}, \text{ hence } \tan\tfrac{1}{2}(\omega + \phi)$$

$$= \frac{m+1}{2}\tan\phi.$$

But in order that ω should increase gradually from 0 to $\frac{1}{2}\pi$, as ϕ does, h must be less than 1, and m less than 3.

Again, if c and α are two moduli, so related that

$$1 - \alpha^2\sin^2\omega = (1 - c^2\sin^2\phi)\left(\frac{1 - \frac{k}{m}\sin^2\phi}{1 + k\sin^2\phi}\right)^2,$$

it will be found possible in general to satisfy the above equation, and thus we get

$$\alpha^2 = \frac{(m-1)(m+3)^3}{16m^3}, \text{ and } c^2 = \frac{(m-1)^3(m+3)}{16m};$$

whence m must be between 3 and 1 in order that α and c may both be real proper fractions.

Hence $$\Delta(\alpha, \omega) = \frac{1 - \frac{k}{m}\sin^2\phi}{1 + k\sin^2\phi}\Delta(c,\phi);$$

and this, combined with the above differential relation, gives

$$\frac{d\omega}{\Delta(\alpha, \omega)} = \frac{m\,d\phi}{\Delta(c, \phi)},$$

or, integrating, $\mathrm{F}(\alpha, \omega) = m\,\mathrm{F}(c, \phi)$,—a relation between two functions of the first kind, whose moduli depend in general on the quantity m, which may be taken at will between the limits 1 and 3.

The modulus α is always greater than c, for we have

$$\frac{c}{\alpha} = \frac{m^2 - m}{m + 3} \text{ and } m + 3 - (m^2 - m) = (1 + m)(3 - m),$$

which is always positive. We have seen that α and c are determined by means of the *regulator* m when it is known; it can be found from either of them by solving a biquadratic.

Again, the complements of the moduli are found by

$$\beta^2 = \frac{(m+1)(3-m)^3}{16m^3},\ b^2 = \frac{(m+1)^3(3-m)}{16m},$$

whence follows the simple relation

$$\sqrt{\alpha c} + \sqrt{\beta b} = 1.$$

Application of this transformation to integrals of the second and third kinds gives rise to the remark that the trisection of an indefinite function of the first kind may be reduced to depend on the solution of two cubic equations.

218. Now, starting with a given modulus c, an infinite series of moduli increasing towards the limit 1, and an infinite series decreasing towards the limit 0, may be formed, and we may denote the latter by a notation analogous to the former. Let them be in the increasing order c, c_1, c_{11}, c_{111}, etc., and in the decreasing order, c, c_0, c_{00}, etc.; and similarly for the complements, the regulators, and the amplitudes. Thus, by the first scale, any integral of the first kind, having a given modulus and amplitude, can be transformed into another with any modulus in the series $\ldots c^{00}, c^0, c, c', c'' \ldots$ and from this by the second to any in the other series formed from the same c by a different law, depending on extractions of square and cube roots.

Legendre arranges the moduli in a sort of infinite chessboard, having c in the centre, and the moduli derived according to each scale in rectangular directions, and notices how remarkable is this infinite multitude of transformations which the same function $\mathrm{F}(c, \phi)$ may be submitted to, without changing its nature while preserving the same ratio between the new function and the old for all values of the amplitude; in vain, he adds, might a second example be sought of a function which should be reproduced under so many different forms, and to which, more justly than to the logarithmic spiral, might be applied James Bernoulli's device, "Eadem mutata resurgit."

219. The first volume of the *Traité* also contains the reduction to elliptics of a great number of integrals, the development of elliptic integrals in series proceeding by sines and cosines of multiples of the amplitude, and calculations of some definite integrals, single and double, which can be expressed by elliptic integrals. The *applications* are, in geometry to the surface of an oblique cone, to that of an ellipsoid, and to a geodesic on a spheroid; and in mechanics, to the rotation of a solid, to the motion of a body under the attraction of two fixed centres, to the attraction of homogeneous ellipsoids, and to the orbit described under a given central force.

The second volume contains details of the calculation of the integrals, and such tables of them as have to be constructed in order that the use of these functions may be introduced into analysis just as circular and logarithmic functions are employed. Here, Legendre excludes the thought of reducing to tables functions of the third kind, since they contain besides the principal variable two arbitrary quantities; and so the tables should be of triple entry, a thing altogether unmanageable. Besides these, this volume contains a treatise on Eulerian integrals, and an appendix on spherical functions and on quadratures.

The third volume of the *Traité* contains three supplements to the theory of elliptic functions, dated 1828, 1829, 1832, embodying Legendre's acceptance of the discoveries made by Jacobi and Abel since the publication of the *Traité*.

220. It was owing to the strangeness of his subject that Legendre for more than twenty years found no fellow-

worker in it. "After having employed myself for a great number of years," he says in the preface to the first supplement of the *Traité*, "with the theory of elliptic functions, of which the immortal Euler had laid the foundations, I thought I should collect the results of this long work in a treatise, and this I published in the month of January, 1827. Up to that geometers had taken almost no part in this kind of researches; but hardly had my work seen the light, its name could hardly have become known to scientific foreigners, when I learned with equal surprise and satisfaction that two young geometers, MM. Jacobi of Königsberg and Abel of Christiania, had succeeded by their own studies in perfecting considerably the theory of elliptic functions in its highest parts."

Abel and Jacobi have found not only points of connection for their works with Legendre's investigations, but have been able to adopt a set of methods and points of view from his *Traité*, on the basis of which they have constructed the mighty edifice of the theory of elliptic transcendents. This Jacobi himself subsequently fully recognized. On May 27, 1832, he writes to Legendre:—"In a note at the end of the eighth volume of M. Crelle, I have sought to extol the imperishable merits of the geometer who, besides the numerous and important discoveries with which he has enriched science, has effectually laid the foundations by the glorious labors of his life of two great and extended disciplines which shall henceforth form the α and the ω of every mathematical study. I have at the same time made use of this opportunity to speak of Abel and of his great theorem, which you again have the merit of having first penetrated, and of having shown to posterity that its development is the great task remaining for it to fulfil."

221. Before entering into the developments due to these two celebrated mathematicians we should make some mention of Gauss's labors in the same field. These were mostly found in incomplete sketches at the beginnings of different treatises, or as individual formulæ scattered among his other works. The editor of his collected works has brought them together in the latter part of the third volume, and states that there is evidence that Gauss was acquainted with the relations between the arithmetic geometric mean and the series proceeding by square powers in the year 1794. This *arithmetic geometric mean* is defined in the paper "Determinatio attractionis" published in 1818, where he speaks of it as a peculiar and most expeditious algorithm which he had for many years employed, and intended yet to treat of more fully.

Let m, n be two positive quantities, and put $m' = \frac{1}{2}(m+n)$, $n' = \sqrt{mn}$, so that m' and n' may be their arithmetic and geometric mean, taking the latter always positive. Now take

$$m'' = \tfrac{1}{2}(m'+n'),\ n'' = \sqrt{m'n'},$$

$$m''' = \tfrac{1}{2}(m''+n''),\ n''' = \sqrt{m''n''},$$

and so on. It may be seen that the series m, m', m'', m''', and n, n', n'', n''', etc., rapidly converge to a *common limit*, which we shall denote by μ, and simply call the *arithmetic geometric mean* between m and n. Now we shall demonstrate that $\frac{1}{\mu}$ is the value of the integral

$$\int \frac{d\tau}{2\pi\sqrt{m^2\cos^2\tau + n^2\sin^2\tau}},$$

taken $\tau = 0$ to $\tau = 360°$.

For suppose that the variable τ is expressed by another τ', so that

$$\sin\tau = \frac{2m\sin\tau'}{(m+n)\cos^2\tau' + 2m\sin^2\tau'},$$

it will easily be seen that as τ' increases from 0 to 90°, 180°, 270°, 360°, τ also, though not uniformly, increases through the same range. But, effecting the substitution,

$$\frac{d\tau}{\sqrt{(m^2\cos^2\tau + n^2\sin^2\tau)}} = \frac{d\tau'}{\sqrt{(m'^2\cos^2\tau' + n'^2\sin^2\tau')}};$$

accordingly the values of the integrals

$$\int \frac{d\tau}{2\pi\sqrt{(m^2\cos^2\tau + n^2\sin^2\tau)}},\ \int \frac{d\tau'}{2\pi\sqrt{(m'^2\cos^2\tau' + n'^2\sin^2\tau')}},$$

each taken from 0 to 360° are equal; and, since this may be carried on as far as we please, plainly they are also equal to the value of the integral

$$\int \frac{d\Theta}{2\pi\sqrt{(\mu^2\cos^2\Theta + \mu^2\sin^2\Theta)}},$$

from $\Theta = 0$ to $\Theta = 360°$, which is plainly $\frac{1}{\mu}$.

222. N. H. Abel (1802-29) started in the summer of 1825 to pursue his studies abroad, chiefly at Paris. On his way he made the acquaintance in Berlin of A. L. Crelle, who had long conceived the project of founding a mathematical journal, but was decided to put this into execution by the importance of the numerous memoirs already prepared by Abel (as also by Steiner), who consented to their publication in it. The first number of the journal appeared during Abel's stay in Berlin, and each copy in the first four volumes contained papers by him. These and other published papers are reprinted in the first volume of his collected works (Christiania, 1839). The second volume contains mostly papers found after his death, nearly all in this volume having been written before Abel began his travels. These, therefore, first claim our attention after Legendre's independent investigations.

223. Elliptic integrals have hitherto occupied us. We have mentioned (§ 207) the problem of inversion which leads to elliptic functions, viz., that if $u = F(\kappa, \phi)$, then $\phi = \text{am}\ u$, and if

$$u = \int_0^x \frac{dx}{\sqrt{(1-x^2)(1-\kappa^2x^2)}},\ \text{we have } x = \sin \text{am}\ u.$$

Paper viii. (vol. ii.) is headed "Remarkable properties of the function determined by the equation

$$fy\,.\,dy - dx\left\{(a-y)(a_1-y)(a_2-y)\ .\ .\ .\ (a_m-y)\right\}^{\frac{1}{2}} = 0,$$

fy being any function of y which does not become zero or infinite when $y = a, a_1, a_2, \ .\ .\ .\ a_m$." In it this problem of inversion of the more general (hyperelliptic) integral in which the square root contains a function of the degree $m+1$ is attempted; and, though it has since been shown by Jacobi (*Crelle*, xiii.) that the inversion of hyperelliptic integrals is a different problem from what is here proposed, Abel at any rate in this short paper had established the existence of two periods for elliptic functions.

224. We saw in § 216 that Legendre, in comparing two elliptic integrals of the third kind, found a certain relation connecting with integrals of the first and second kinds two such integrals of the third kind, in which the argument and parameter are interchanged. This relation recurs to us in an extended form in the paper of Abel (ix., vol. ii.) "On a remarkable property of a very extended class of transcendent functions." Defining y or ψx by the differential equation $y\,.\,fx + \frac{dy}{dx}\cdot\phi x = 0$, where $\phi x = \alpha + \alpha_1 x + \alpha_2 x^2 + \ .\ .\ .$, and $fx = \beta + \beta_1 x + \beta_2 x^2 + \ .\ .\ .$, he gets

$$\frac{1}{\psi a}\cdot\int\frac{\psi x\,.\,dx}{x-a} - \psi x\,.\,\phi x\int\frac{da}{(a-x,\phi a\,.\,\psi a}$$

$$= \Sigma\big((n+2)\alpha_{m+n+2} - \beta_{m+n+1}\big)\int\frac{a^m da}{\phi a\,.\,\psi a}\cdot\int x^n\psi x dx,$$

the integrals in x being taken from a value of x which makes $\psi x\,.\,\phi x$ vanish, and those in a from a value of a which destroys $\frac{1}{\psi a}$. When we put $\psi x = \frac{1}{\sqrt{\phi x}}$ in this, it becomes the theorem for the interchange of argument and parameter for hyperelliptic integrals.

225. "The first works of Abel which attracted attention," writes his editor, "were his memoirs on the impossibility of the general resolution of algebraic equations higher than the fourth degree, and his researches on elliptic functions. Simultaneously with Abel, and without being acquainted with his works, M. Jacobi of Königsberg began to treat the theory of elliptic functions. Thus a rivalry exists between these two men of exalted genius in their treatises on these functions. Abel told me that during his stay at Paris in 1826 he had already completed the essential part of the principles he subsequently enunciated regarding these functions, and that he would have much wished to postpone the publication of his discoveries until he could compose a complete theory of them, had not in the meanwhile M. Jacobi entered the lists."

226. On October 24, 1826, Abel wrote from Paris:—"I have just finished a large treatise on a certain class of transcendent functions for presentation to the Institute, and that will take place next Monday. I dare without ostentation say it is a treatise which will give satisfaction. I am curious to hear the opinion of the Institute about it." He had not deceived himself in the significance and reach of this fundamental theorem; yet in the Academy judgment upon the work was deferred, so that Abel two years later (Jan. 6, 1829), felt himself called upon to send to Crelle the following, which appeared in the fourth volume of the *Journal* (*Works*, i. p. 324).

227. "*Demonstration of a general property of a certain class of transcendent functions.*

"*Theorem.*—Let y be a function of x which satisfies any irreducible equation of the form

$$0 = p_0 + p_1 y + p_2 y^2 + \ldots + p_{n-1} y^{n-1} + y^n \quad . \quad . \quad . \quad (1),$$

where $p_0, p_1, \ldots p_{n-1}$ are integer functions of the variable x. In like manner let $q_0, q_1 \ldots q_{n-1}$ be integer functions of x, and

$$0 = q_0 + q_1 y + q_2 y^2 + \ldots + q_{n-1} y^{n-1} \quad . \quad . \quad . \quad . \quad (2)$$

a similar equation, and let us suppose the coefficients of the different powers of x in these functions variable. Let these be denoted by $a, a', a'' \ldots$. By reason of the two equations (1) and (2), x will be a function of a, a', a'', etc.; and we shall determine its values by eliminating y. Let us denote by

$$\rho = 0 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

the result of elimination, so that ρ will contain only the variables x, a, a', etc. Let μ be the degree of this equation in x, and let its μ roots be

$$x_1, x_2, \ldots x_\mu \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

which will be so many functions of a, a', a'', etc.

"Now, if $f(x, y)$ denote any *rational* function of x and y, and we make

$$\psi x \quad \int f(x, y)dx \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

then the transcendent function $\psi(x)$ will possess the general property expressed by the following equation:

$$\left.\begin{array}{l} \psi x_1 + \psi x_2 + \ldots \psi x_\mu = u + k_1 \log v_1 \\ \quad + k_2 \log v_2 + \ldots + k_n \log v_n \end{array}\right\} \ldots (6),$$

$u, v_1, v_2, \ldots v_n$, being rational functions of $a, a', a'', \ldots$ and $k_1, k_2, \ldots k_n$, constants.

"*Demonstration.*—To prove this theorem it is enough to express the first member of equation (6) as a function of a, a', a'', etc.; for thereby it will reduce to a rational differential, as we shall see.

"First, the two equations (1) and (2) will give y as a rational function of $x, a, a', a'' \ldots$. Similarly the equation (3) will give for dx an expression of the form

$$dx = \alpha da + \alpha' da' + \alpha'' da'' + \text{etc.},$$

where $\alpha, \alpha', \alpha'' \ldots$ are rational functions of x, a, a', a'', etc. Thence it follows that the differential $f(x, y)dx$ can be put under the form $f(x,y)dx = \phi x da + \phi_1 x da' + \phi_2 x da'' +$ etc., where $\phi x, \phi_1 x, \ldots$ are rational functions of x, a, a', a'', etc. Integrating, we get $\psi x = \int(\phi x da + \phi_1 x da' + \ldots)$; and from this we conclude, since this equation holds when we put for x its μ values,

$$\left.\begin{array}{l} \psi x_1 + \psi x_2 + \ldots + \psi x_\mu = \int(\phi x_1 + \phi x_2 + \ldots + \phi x_\mu)da \\ \quad + \int(\phi_1 x_1 + \phi_1 x_2 + \ldots + \phi_1 x_\mu)da' + \text{etc.} \end{array}\right\} (7).$$

"In this equation the coefficients of the differentials da, da', etc., are rational functions of $a, a', a'' \ldots$ and of $x_1, x_2, \ldots x_\mu$; but they are besides symmetrical in $x_1, x_2, \ldots x_\mu$; therefore, by a well-known theorem, they can be expressed rationally in terms of $a, a', a'' \ldots$ and the coefficients of the equation $\rho = 0$; but these latter are themselves rational functions of the variables $a, a', a'' \ldots$ so that finally the coefficients of da, da', da'', etc., of equation (7) will be so too. Therefore, integrating, we have an equation of the form (6).

"I propose on another occasion to develop numerous applications of this theorem, which will throw a great light on the nature of the transcendental functions it deals with."

228. Abel died of consumption, April 6, 1829, having been confined to bed nearly three months; and of the applications promised nothing appeared or has since been found in his remains. Moreover, except the note that he had presented the memoir to the Academy, which appears in the paper "On some general properties of a certain sort of transcendental functions" (*Works*, i. p. 288), Abel hardly seems to have expressly referred to it, though he mentioned the theorem (November 25, 1828, *Works*, ii. p. 258) to Legendre, adding that on this general property he had in fact founded the whole theory of elliptic functions.

229. But notwithstanding, his contemporaries were not slow to estimate the value of his analysis. The statement in *Crelle's Journal* revealed to Jacobi the entire significance of this "fundamental theorem of analysis," and his admiration breaks forth to Legendre on the 14th March, 1829:—"What a discovery of Abel's is that generalization of Euler's integral? But how does it happen that this discovery, perhaps the most important our century has made in mathematics, though communicated two years since to the Academy, has been able to escape the attention both of you and your fellow members?" To this question Legendre answers (April 8, 1829):—"I shall not close this letter without answering yours relative to M. Abel's beautiful paper, which was printed in the last number of *Crelle's Journal*, and which had been presented to the Academy by its author in the last months of 1826. M. Poisson was then president of the Academy. The committee named to examine the memoir were M. Cauchy and myself. We perceived that the memoir was almost illegible; it was written with very faint ink, the characters badly formed; it was agreed on that we should ask the author for a better copy, and one easier to be read. So things remained. M. Cauchy kept the manuscript up to this without doing anything further about it. The author, M. Abel, appears to have gone away without caring what became of his memoir. He furnished no copy, and no report was made. However, I have asked M. Cauchy to give me the manuscript, which never was in my hands, and I shall see what there is to be done, to make up, if possible, for the little attention he bestowed on a production which no doubt deserved a better fate."

230. The third and last supplement of Legendre to his great work is dated March 4, 1832, and concludes as follows: "Here we shall terminate the additions we proposed to make to our work, taking advantage of the recent discoveries of MM. Abel and Jacobi in the theory of elliptic functions. It will be remarked that the most important of these additions consists in the new branch of analysis we have deduced from the theorem of M. Abel, and which had hitherto remained quite unknown to geometers. This branch of analysis, to which we have given the name 'theory of ultra-elliptic functions,' is of infinitely greater extent than that of elliptic functions, with which it has very intimate relations; it is composed of an indefinite number of classes, each of which divides into three kinds, as do elliptic functions, having besides a great number of properties. We have only been able to glance at this matter, but no doubt it will be gradually enriched by the labors of geometers, and at length will form one of the finest parts of the analysis of transcendents." At nearly the same time Legendre wrote to Crelle—"The work, so far as I am concerned, has given me the profound satisfaction of rendering conspicuous homage to the genius of M. Abel, in making felt all the merit of the beautiful theorem which was his discovery, and which may be characterized as *Monumentum ære perennius*." In his remarks on the third supplement of Legendre (*Crelle*, viii.) occur the notable words of Jacobi: "We hold it (the Abelian theorem) to be the greatest mathematical discovery of our time, although it remains for a future, perhaps long distant, work to manifest its whole significance."

231. The name which Jacobi thus applied, the Abelian theorem, has since adhered, and the functions to which it refers have been called Abelian functions, the term hyper- or ultra-elliptic having been restricted to that particular class in which the square root of a polynomial is the only irrational quantity introduced; while Abelian functions may depend on any irrationality. The neglected paper of Abel appeared in the *Memoirs of the Institute* in 1841.

232. But, though the Abelian theorem was thus published during its author's stay in Paris, his labors in other departments of the theory of transcendents suffered no intermission. In December, 1826, he writes—"I have written a large memoir on elliptic functions which contains much that is curious, and which I flatter myself will not fail to fix the attention of the literary world. Amongst other things it treats of the division of the arc of the lemniscate. I have found that with rule and compass the lemniscate can be divided into $2^n + 1$ equal parts, when this number $2^n + 1$ is prime. The division depends on an equation of the degree $(2^n + 1)^2 - 1$, but I have found its complete solution by means of square roots. This has revealed to me at the same time the mystery in which Mr. Gauss's theory of the division of the circumference of the circle has been wrapped up. I see clearly how he arrived at it," referring to the last section of the *Disquisitiones Arithmeticæ* of Gauss, published in 1801.

233. C. G. J. Jacobi (born Dec. 10, 1804, died Feb. 18, 1851) appeared first as a discoverer in connection with our subject in the "Extracts of two letters to the editor," published in September, 1827, in the *Astronomische Nachrichten* of Schumacher, and reprinted at the beginning of the collected *Works*, 1881. We have seen that Legendre discerned the vast importance of the relations which he called Landen's transformation, and discovered with increased wonder the further transformation of the third order, which became public in January of this same year, 1827, in the *Traité*. But in his first letter Jacobi states: "The integrals of the form $\int \frac{d\phi}{\sqrt{1 - c^2 \sin^2\phi}}$ for different moduli c, belong to different transcendents. Only one system of moduli is known for

which they reduce into one another, and M. Legendre in his *Exercices* says even that there is only this one. But in fact there are as many of these systems as there are prime numbers, that is to say, there is an infinite number of these systems, all independent, each answering to a prime number; the system heretofore known answers to the prime number 2."

This is already, without proof, a statement of the general theorem of transformation of elliptic integrals of the first kind. If U be a certain odd function of sin ψ of any degree n, and V a certain even function of sin ψ of degree $n-1$, then, putting $\sin\phi = \frac{\mathrm{U}}{\mathrm{V}}$, the coefficients of these functions may be determined so as to satisfy $\int \frac{d\phi}{\sqrt{1-c^2\sin^2\phi}} = m\int \frac{d\psi}{\sqrt{1-k^2\sin^2\psi}}$; and each of these substitutions gives a new system of moduli.

Further, Jacobi notices that sin ψ can be in an almost analogous manner expressed by sin θ, so as by composition of the two integral equations to satisfy the relation

$$\int \frac{d\phi}{\sqrt{1-c^2\sin^2\phi}} = n\int \frac{d\theta}{\sqrt{1-c^2\sin^2\theta}}.$$

Thus the substitution which serves to give n times the transcendent can be divided into two of a simpler nature, and this substitution gives sin ϕ expressed by a fraction whose numerator contains the odd powers of sin θ up to n^2, and its denominator the even powers of it up to n^2-1.

Without giving the general proof, the transformations of the third and of the fifth degrees are here actually effected, and connected with multiplication and division for the numbers 3 and 5; and thus for the first time the algebraic solution of the equation of the ninth degree which trisects the transcendent is given.

234. Legendre could not at first believe in the existence of an algebraic transformation belonging to any arbitrary degree, and thought Jacobi trusted to mere induction. But he soon admitted the profundity and rigor of Jacobi's analysis on receiving from him a letter, dated Aug. 5, 1827, in which it is stated that, if p be any odd number, we can by a rational substitution,

$$x = \frac{z(\mathrm{A} + \mathrm{A}'z^2 + \ldots + \mathrm{A}''z^{p_2-1})}{\mathrm{B} + \mathrm{B}'z^2 + \ldots + \mathrm{B}''z^{p^2-1}},$$

arrive at the equation

$$\frac{dx}{\sqrt{(1-x^2)(1-\kappa^2x^2)}} = p\frac{dz}{\sqrt{(1-z^2)(1-\kappa^2z^2)}}.$$

Moreover, this substitution can be replaced by two in succession,

$$x = \frac{y(a + a'y^2 + \ldots + a''y^{p-1})}{b + b'y^2 + \ldots b''y^{p-1}},$$

$$y = \frac{z(\alpha + \alpha'z^2 + \ldots + \alpha''z^{p-1})}{\beta + \beta'z^2 + \ldots + \beta''z^{p-1}},$$

the first substitution transforming the elliptic function into another of different modulus, so that

$$\frac{dx}{\sqrt{(1-x^2)(1-\kappa^2x^2)}} = \frac{\mathrm{M}dy}{\sqrt{(1-y^2)(1-\lambda^2y^2)}},$$

and the second returning to the original

$$\frac{dy}{\sqrt{(1-y^2)(1-\lambda^2y^2)}} = \frac{p}{\mathrm{M}}\frac{dz}{\sqrt{(1-z^2)(1-\kappa^2z^2)}}.$$

Now, giving p different values, we see that each given modulus is one in an infinite scale of moduli into which it may be transformed by an algebraic and even rational substitution. This letter, moreover, contained the two theorems giving the general formula in a trigonometric form.

235. Subsequently Jacobi, on January 12, 1828, brought under the notice of Legendre the works of Abel on elliptic functions, which Crelle had published,—but in his own notation. Abel, he says, begins with the analytic expression of all the roots of the equations of higher degrees on which the division of elliptic functions depends. Taking $\sin\phi = i\tan\psi$, where $i = \sqrt{-1}$, and

$$\int \frac{d\phi}{\sqrt{1-\kappa^2\sin^2\phi}} = \xi,$$

we have, if κ' be the complement of κ,

$$\frac{d\phi}{\sqrt{1-\kappa^2\sin^2\phi}} = \frac{id\psi}{\sqrt{1-\kappa'^2\sin^2\psi}},$$

whence $\sin\mathrm{am}\,(i\xi, \kappa) = i\tan\mathrm{am}\,(\xi, \kappa')$,
which is a "fundamental theorem of M. Abel."

Further, we have in general $\sin\mathrm{am}\,(\xi + 4m\mathrm{K} + 4m'i\mathrm{K}') = \sin\mathrm{am}\,\xi$, where m and m' are positive or negative integers, and K is the complete function

$$\int_0^{\frac{\pi}{2}} \frac{d\phi}{\sqrt{1-\kappa^2\sin^2\phi}},$$

and K$'$ the complete function corresponding to κ'.

We see then that the roots of this higher equation for dividing the elliptic function ξ into n parts will be of the form

$$\sin\mathrm{am}\frac{\xi + 4m\mathrm{K} + 4m'\mathrm{K}'i}{n};$$

a formula which involves as many as n^2 roots, if we make m, m' successively take the values 0, 1, 2, . . . $n-1$.

Abel next reduces the division of any elliptic function ξ to the division of the complete function K. In fact, if α, β be any roots of $x^n = 1$, the expression

$$\left(\Sigma\alpha^m\beta^{m'}\sin\mathrm{am}\frac{\xi + 4m\mathrm{K} + 4m'i\mathrm{K}'}{n}\right)^n,$$

giving m, m' all the values 0, 1, 2 . . . $n-1$, will not change if we put instead of $\sin\mathrm{am}\,\frac{\xi}{n}$ any other root, $\sin\mathrm{am}\,\frac{\xi + 4\mu\mathrm{K} + 4\mu'i\mathrm{K}'}{n}$, it will thus be symmetrical in these roots, and may therefore be expressed by $\sin\mathrm{am}\,\xi$, and by constant but irrational quantities of the form $\sin\mathrm{am}\,\frac{4m\mathrm{K} + 4m'i\mathrm{K}'}{n}$.

Now giving α, β all possible values produces n^2 combinations, and thereby the values of all the roots. The division of the complete function, which depends in general on an equation of the $\frac{1}{2}(n^2-1)$ degree, is reduced to one of the $n+1$ degree, n being a prime number. For if $\omega = \frac{4\mu\mathrm{K} + 4\mu'\mathrm{K}'i}{n}$, and g be a primitive root of the congruence $x^{n-1} \equiv 1 \pmod{n}$, also $\phi\,(\omega)$ any trigonometric function of the amplitude of ω, and α a root of $x^{n-1} = 1$, we attain this by considering the expression

$$[\phi(\omega) + \alpha\phi(g\omega) + \alpha^2\phi(g^2\omega) + \ldots + \alpha^{n-2}\phi(g^{n-2}\omega)]^{n-1}$$

which is symmetrical in

$$\phi(\omega), \phi(g\omega), \phi(g^2\omega) \ldots \phi(g^{n-2}\omega).$$

But symmetric functions of these quantities can only have $n+1$ different values, answering to $\mu = 0$, $\mu' = 1$; $\mu = 1$, $\mu' = 0$; $\mu = 1$, $\mu' = 1, 2, 3, \ldots n-1$. So they will be determined by an algebraic equation of the degree $n+1$.

In conclusion, Jacobi mentions researches of his own, which led him to the conclusion that if a modulus κ can be transformed into another λ, they are connected by an algebraic equation of the degree $n+1$, if the transformation be of the order of the number n, supposed prime. These symmetric equations are, for $n = 3$ and 5,

$$u^4 - v^4 \pm 2uv(1-u^2v^2) = 0,\ u^6 - v^6$$
$$+ 5u^2v^2(u^2-v^2) \pm 4uv(1-u^4v^4) = 0,$$

putting $u = \sqrt[4]{\kappa}$, $v = \sqrt[4]{\lambda}$.

These equations he names *modular equations*, and notices as remarkable that they have their simplest forms when expressed in the fourth roots of the moduli. He also gives the differential equation of the third degree which all these algebraic equations satisfy, viz.,

$$3(d\kappa^2d^2\lambda^2 - d\lambda^2d^2\kappa^2) - 2d\kappa d\lambda(d\kappa d^3\lambda - d\lambda d^3\kappa)$$
$$+ d\kappa^2d\lambda^2\cdot\left[\left(\frac{1+\kappa^2}{\kappa-\kappa^3}\right)^2 d\kappa - \left(\frac{1+\lambda^2}{\lambda-\lambda^3}\right)^2 d\lambda^2\right] = 0.$$

Moreover, in some cases the same modulus reappears, and the transformation becomes multiplication. This takes place in all cases when n is the sum of two squares, $n = a^2 + 4b^2$, κ being $\sqrt{\frac{1}{2}}$, and the elliptic function becomes multiplied by $a \pm 2bi$. Similarly with all moduli which are connected by any scale with $\kappa = \sqrt{\frac{1}{2}}$, a kind of multiplication not having an analogue in circular arcs.

236. In answer to a request of Legendre that he would furnish him with the clue to his discoveries, Jacobi wrote, April 12, 1828: "Having found (March, 1827) the equation

$$\frac{\mathrm{T}}{\mathrm{M}} = \mathrm{V}\frac{d\mathrm{U}}{dx} - \mathrm{U}\frac{d\mathrm{V}}{dx},$$

I recognized that for any number, n, transformation was a *determinate* problem of algebraic analysis, the number of arbitrary constants being always equal to that of conditions. By indeterminate coefficients I formed the transformations for the numbers 3 and 5. The biquadratic equation to which the former led me having nearly the same form as that which serves for trisection, I began to suspect some relation. Fortunately I happened to remark in these two cases the other transformation complementary to multiplication. At this stage I wrote my first letter to M. Schumacher, the method being general and verified by examples. Subsequently, examining more closely the two substitutions $z=\frac{ay+by^3}{1+cy^2}$, $y=\frac{a'x+b'x^3}{1+c'x^2}$ under the form presented in my first letter, I saw that when we put $x=\sin\operatorname{am}\frac{2K}{3}$, z must vanish, and, as in the said form $\frac{b}{a}$ was positive, I thence concluded that y must vanish also. In this manner I found by induction the resolution into factors, which being confirmed by examples, I gave the general theorem in my second letter. Having remarked the equation $\sin\operatorname{am}(i\xi,\kappa)=i\tan\operatorname{am}(\xi,\kappa')$, I next drew from it the transformation from κ' to λ'. I had then two different transformations, one from κ to a smaller modulus λ, the other from κ' to a larger one λ'. Thence I conjectured that exchanging *inter se* κ' and λ, κ and λ', the analytic expression of the complementary transformation would be got. The demonstrations were found only subsequently."

237. Equally interesting is Legendre's reply (June 16, 1828): "As to what you told me of the train of ideas which led you to your beautiful discoveries on elliptic functions, I see that we have both run some risks,—you in announcing discoveries not yet invested with the seal of a rigorous demonstration, and I in publicly and unrestrictedly giving them my full and entire approbation. We have neither of us to repent of what we have done. . . . I saw very clearly that results such as those you had obtained could be no effect of chance or of a faulty induction, but only of a profound theory based upon the nature of things."

238. Of Gauss's investigations in this branch of mathematics Jacobi makes mention in his first letter to Legendre (August 5, 1827). These researches "are not the only ones which have been undertaken in Germany in the same subject. M. Gauss having heard of them let me know that he had developed as far back as 1808 the cases of division into 3, 5, and 7 parts, and found at the same time the new scales of moduli referring to them." Again, April 12, 1828: "As to M. Gauss, he has not yet published anything in elliptic functions, but it is certain he has made beautiful discoveries. If he has been anticipated and perhaps surpassed, it is a penalty due to the veil of mystery he has spread over his works. I am not personally acquainted with him, as I studied philology at Berlin, where there are no distinguished geometers." Legendre, however, cannot believe that discoveries of such reach can be left unpublished, as was actually the case with Gauss. "If M. Gauss," Legendre writes to Jacobi, April 14, 1828, "had fallen upon such discoveries, which in my eyes surpass all hitherto done in analysis, most assuredly he would have lost no time in publishing them."

239. Simultaneously with the announcements of Jacobi just mentioned there appeared in September, 1827, in *Crelle*, the first part of Abel's "Recherches sur les fonctions elliptiques," and accompanying the second part (Feb. 12, 1828) a statement that, "having finished the preceding memoir on elliptic functions, a note on the same functions by Mr. C. G. J. Jacobi, inserted in No. 123 of M. Schumacher's *Nachrichten*, has reached me. M. Jacobi gives the following theorem. . . . This elegant theorem, which M. Jacobi gives without demonstration, is contained as a particular case in formula 227 of the foregoing memoir (which is the formula of § 246 *infra*), and is fundamentally the same as that of formula 270." This he proceeds to show.

240. The "Recherches" present a great and complete theory of elliptic transcendents. Starting with the inverse function $\phi(\alpha)$ as that determined by $\alpha=\int\frac{d\theta}{\sqrt{1-c^2\sin^2\theta}}$ and $\sin\theta=\phi\alpha=x$, which by $d\theta\sqrt{1-\sin^2\theta}=d\phi\alpha=dx$ gives $\alpha=\int_0\frac{dx}{\sqrt{(1-x^2)(1-c^2x^2)}}$; Abel noticed that the formulæ become simpler by supposing c^2 negative $=-e^2$, and for symmetry writes $1-c^2x^2$ instead of $1-x^2$, so that the function $\phi\alpha=x$ will be given by the equation

$$\alpha=\int_0\frac{dx}{\sqrt{(1-c^2x^2)(1+e^2x^2)}},$$

or by
$$\phi'\alpha=\sqrt{(1-c^2\phi^2\alpha)(1+e^2\phi^2\alpha)},$$

and for brevity two other functions

$f\alpha=\sqrt{1-c^2\phi^2\alpha}$, $F\alpha=\sqrt{1+e^2\phi^2\alpha}$ are introduced.

After establishing the double periodicity, and determining the zero and infinite values of these functions, Abel proceeds to the development of the formulæ of multiplication to determine $\phi(n\alpha)$, $f(n\alpha)$, $F(n\alpha)$ in rational functions of $\phi(\alpha)$, $f(\alpha)$, $F(\alpha)$.

He next enters on the solution of the more difficult problem of the division of elliptic functions, which is the principal object of the memoir, Abel proves the algebraic expressibility of the functions

$$\phi\left(\frac{\alpha}{2n+1}\right),\quad f\left(\frac{\alpha}{2n+1}\right),\quad F\left(\frac{\alpha}{2n+1}\right)$$

as functions of $\phi(\alpha)$, $f(\alpha)$, $F(\alpha)$ in the form

$$\phi(\beta)=\frac{1}{2n+1}\left\{\phi_1(\beta)+\left(C_1+\sqrt{C_1^2-D_1^{2n+1}}\right)^{\frac{1}{2n+1}}+\ \cdot\ \cdot\ \cdot\right.$$
$$\left.+\left(C_{2n}+\sqrt{C_{2n}^2-D_{2n}^{2n+1}}\right)^{\frac{1}{2n+1}}\right\};$$

in which

$$\phi_1\beta=\phi(2n+1)\beta+\frac{1}{2n+1}\left\{\left(A_1+\sqrt{A_1^2-B_1^{2n+1}}\right)^{\frac{1}{2n+1}}\right.$$
$$+\left(A_2+\sqrt{A_2^2-B_2^{2n+1}}\right)^{\frac{1}{2n+1}}+\ \cdot\ \cdot\ \cdot$$
$$\left.+\left(A_{2n}+\sqrt{A_{2n}^2-B_{2n}^{2n+1}}\right)^{\frac{1}{2n+1}}\right\},$$

and the quantities C, D are rational functions of $\phi_1(\beta)$, while the quantities A, B are similar functions of $\phi(2n+1)\beta$. Thus these equations give $\phi(\beta)$ algebraically expressed by $\phi_1(\beta)$, and then $\phi_1(\beta)$ algebraically by $\phi(2n+1)\beta$. So replacing β by $\frac{\alpha}{2n+1}$, we get $\phi\left(\frac{\alpha}{2n+1}\right)$ as an algebraic function of $\phi\alpha$; and similarly for f and F.

241. The priority of this beautiful discovery Jacobi ascribes unconditionally to Abel. To Legendre he writes (March 14, 1829):—"You suppose I have found means of expressing algebraically trigonometric functions of the amplitudes you denote by α_m, adding that without that my formula would contain coefficients I could not determine. But that is *quite impossible* in the general case, and is done only for special values of the modulus. My formula, which gives the algebraic expression for sin am u by means of sin am nu, supposes known the section of the complete function. In this manner, for more than a century, the division of an arc of a circle could be solved algebraically, supposing known that of the complete circumference, this latter having been given generally only in these later times by the works of M. Gauss. . . . You see then that M. Abel has proved this important theorem, as you call it, in his first memoir on elliptic functions, although he has not dealt in it with transformation, and does not appear even to have thought when he wrote that his formulæ and theorems would find such an application. The transformed modulus, or, which amounts to the same thing, the regulator, being supposed known, it is still necessary to resolve an equation of degree $\frac{1}{2}(n-1)$ to arrive at the quantities $\sin^2\operatorname{am}(2p\omega)$, or at the section of the complete function. Thus you had only to solve a quadratic in the case of $n=5$. M. Abel proved that M. Gauss's method applies nearly word for word to the solution of these equations, so that it is only the modular equations that we are unable to solve algebraically.

242. Starting from the solution of the problem of multiplication and division, $\phi(2n+1)\beta$ is exhibited by Abel as the quotient of two double products, the factors of which depend linearly on $\phi(\beta)$. Thence, putting $\beta=\frac{\alpha}{2n+1}$ and $n=\infty$, the development of the inverse function $\phi(\alpha)$ is derived in double products and double sums, the factors of which are linear in α; accordingly a unique analytic expression is found for the function heretofore defined only by its properties. The reduction of the double products and double sums to simple products and simple sums, the product development and breaking up into partial fractions of the elliptic functions, follow then without further difficulties.

243. With the publication of the "Recherches" Abel clears at one bound the limits of the investigations of Jacobi hitherto published, though the first part devotes no attention to the problem of transformation of elliptic integrals. Moreover, this work drew from Gauss the remark:—"M. Abel has anticipated me at least in a third part. He has just trodden precisely the same path I went along in 1798. And so I am not at all astonished at his arriving, for the most part, at the same results. Besides, as in his deduction he has displayed so much sagacity,

penetration, and elegance, I feel myself by it relieved from the publication of my own researches."

244. The same volume of *Crelle* contains, besides the first part of the "Recherches," indications in the paper "Problems and Theorems" that Abel was at the time in possession, not only of the theory of rational transformation which Jacobi treated, but of the general algebraic transformation, as has been made manifest subsequently in his collected works.

245. Before Jacobi had read the "Recherches" he published a proof of the general theorem of rational transformation in No. 127 of Schumacher's *Nachrichten*, December, 1827. It is based on enumeration of the constants available, and fixing the conditions in order that the substitution $y = \frac{\mathrm{U}}{\mathrm{V}}$ may satisfy the differential equation

$$\frac{dy}{\sqrt{(1-\alpha y)(1-\alpha' y)(1-\alpha'' y)(1-\alpha''' y)}}$$

$$= \frac{dx}{\mathrm{M}\sqrt{(1-\beta x)(1-\beta' x)(1-\beta'' x)(1-\beta''' x)}} \cdot$$

He introduces the unique inverse function which he calls sine of the amplitude, sin am, and gives the value of

$$1-y = \frac{(1 \mp x)\left(1 \pm \dfrac{x}{\sin\operatorname{coam}\dfrac{2\mathrm{K}}{2n+1}}\right)^2 \cdots \left(1-\dfrac{x}{\sin\operatorname{coam}\dfrac{2n\mathrm{K}}{2n+1}}\right)^2}{\left(1-\kappa^2 x^2 \sin^2\operatorname{am}\dfrac{2\mathrm{K}}{2n+1}\right)\cdots\left(1-\kappa^2 x^2 \sin^2\operatorname{am}\dfrac{2n\mathrm{K}}{2n+1}\right)}$$

as satisfying the differential equation (M being constant)

$$\frac{dx}{\sqrt{(1-x^2)(1-\kappa^2x^2)}} = \mathrm{M}\frac{dy}{\sqrt{(1-y^2)(1-\lambda^2y^2)}} \cdot$$

The value of y is derived from this, and Jacobi remarks that this theorem holds generally, but does not embrace all the solutions of the problem.

246. The second part of the "Recherches" was finished by Abel, February 12, 1828, and appeared immediately in *Crelle*. The first problem treated is the algebraic expressibility of the function $\phi\left(\frac{\omega}{n}\right)$, when certain relations, as for the lemniscate, hold between e and c. The principal application of this is the expression of the function by square roots whenever n is of the form 2^n or $1+2^n$, the latter being prime. He then proceeds to deal with the general treatment of rational transformation, which he presents in the following form.

If α be $\frac{(m+\mu)\omega + (m-\mu)\varpi i}{2n+1}$, where at least one of the integers m and μ is prime to $2n+1$, we shall have

$$\int\frac{dy}{[(1-c_1^2y^2)(1+e_1^2y^2)]^{\frac{1}{2}}} = \pm a\int\frac{dx}{[(1-c^2x^2)(1+e^2x^2)]^{\frac{1}{2}}},$$

where

$$y = f.x.\frac{(\phi^2\alpha - x^2)(\phi^2 2\alpha - x^2)\ldots(\phi^2 n\alpha - x^2}{(1+e^2c^2\phi^2\alpha . x^2)(1+e^2c^2\phi^2 2\alpha . x^2)\ldots(1+e^2c^2\phi^2 n\alpha . x^2)},$$

$$\frac{1}{c_1} = \frac{f}{c}\left[\phi\left(\frac{\omega}{2}+\alpha\right).\phi\left(\frac{\omega}{2}+2\alpha\right)\ldots\phi\left(\frac{\omega}{2}+n\alpha\right)\right]^2,$$

$$\frac{1}{e_1} = \frac{f}{e}\left[\phi\left(\frac{\varpi i}{2}+\alpha\right).\phi\left(\frac{\varpi i}{2}+2\alpha\right)\ldots\phi\left(\frac{\varpi i}{2}+n\alpha\right)\right]^2,$$

$$a = f.\phi\alpha . \phi 2\alpha . \phi 3\alpha \ldots \phi n\alpha)^2,$$

f being an indeterminate, so that there only exists a single relation between the quantities c_1, e_1, c, e. The section concludes with the words—"To have a complete theory of the transformation of elliptic functions, it would be necessary to know all the transformations possible; now I have succeeded in demonstrating that they are all got by combining that of M. Legendre with those contained in the above formula, *even when we are looking for the most general relation between any number of elliptic functions.* This theorem, the consequences of which embrace nearly the whole theory of elliptic functions, has led me to a very great number of fine properties of them."

247. The same number of *Crelle* contained, in an extract from a letter by Jacobi, "Note sur les fonctions elliptiques," the exhibition of sin am as the quotient of two series Θ and H, or as they were subsequently called the θ and θ_1 functions; also, appended to this, the development of $\sqrt{\frac{2\mathrm{K}}{\pi}}$ by powers of $q = e^{\frac{-\pi\mathrm{K}'}{\mathrm{K}}}$, the exponents of which are the squares of the natural numbers; as also the very important development of $\sqrt{\kappa}$ as quotient of two series proceeding by square powers of q and $q^{\frac{1}{4}}$—results whose importance was at once accepted by Legendre. Regarding the result in this paper, that to a given modulus for a prime degree of transformation n there always correspond $n+1$ other transformed moduli got by putting q^n, $q^{\frac{1}{n}}$, $\alpha q^{\frac{1}{n}}$, ... $\alpha^{n-1}q^{\frac{1}{n}}$ for q, where $\alpha^n = 1$, Jacobi remarks, "Thus M. Abel will see that imaginary transformations had not escaped me."

248. Jacobi's well-known construction *for the addition and multiplication of elliptic functions by the arcs determined on a circle by the vertices of an inscribed polygon, whose sides touch other circles coaxal with it* (or, as he entitled it, application of elliptic transcendents to a known problem of elementary geometry—to find the relation between the distance of the centres and the radii of two circles, one inscribed in, and the other circumscribed to, an irregular polygon), is of about the same date, April 1, 1828.

Immediately afterwards, Jacobi, still ignorant of the second part of Abel's "Recherches," communicates to Legendre (April 12, 1828) the forms of development detailed in the work we have just spoken of for the sin am, for the modulus of the integral, and for the period K, and notices that these formulæ will not be without interest for the celebrated geometers who are engaged with the motion of heat,—numerators and denominators of the fractions by which the trigonometric functions of the amplitude have been expressed being often met with in that question.

249. Abel sought to generalize the problem of transformation, in the publication of which he was anticipated by Jacobi.

"We may regard this theory," he says (May 27, 1828), "from a much more general point of view, proposing as a problem of indeterminate analysis to find all possible transformations of an elliptic function which can be effected in a certain manner. I have attained the complete resolution of a great number of problems of this kind,—among them the following:—To find all possible cases in which we can satisfy the differential equation

$$\frac{dy}{\sqrt{(1-c_1^2y^2)(1-e_1^2y^2)}} = \pm a\frac{dx}{\sqrt{(1-c^2x^2)(1-e^2x^2)}} \quad . \quad . \quad (1)$$

by putting for y an algebraic function of x, rational or irrational. This problem may be reduced to the case that y is rational. For we can show that, if (1) holds for an irrational value of y, we can always deduce from it another of the same form in which y is rational by suitably changing the coefficient a,—the quantities c_1, e_1, c, e remaining the same. The first method which presents itself for resolving this problem when y is rational is that of undetermined coefficients. But this is a very fatiguing process. The following, I believe, deserves the attention of geometers, leading as it does to a complete solution in the simplest manner."

The theorem of the reducibility of the general problem of transformation to the rational is, however, stated without proof in this paper, but the problem of rational transformation, based on considerations of periods for the original and transformed elliptic function, is strictly treated. It is shown to resolve into simpler analogous problems whenever the number characteristic of the transformation is a compound one, and the equation of transformation itself is stated to be algebraically soluble. Lastly, Abel enters more closely into the case of equality of the transformed moduli of the integrals (viz., $e_1 = e$, $c_1 = c$), which has subsequently constituted the theory of the complex multiplication of elliptic functions. The multiplier a of the transformation is found in the necessary form $\mu' + \sqrt{-\mu}$, where μ' and μ signify two rational numbers of which the latter must be essentially positive; and Abel adds—"If we attribute to a such a value, we can find an infinity of different values of e and c which render the problem possible. All these values are expressible by *radicals.*" Regarding the subject of this paper, Jacobi remarks to Legendre (June 14, 1829), "Abel's principal merit in the theory of transformation consists in his demonstration that *our formulæ embrace all possible algebraic substitutions*, and this gives a high degree of perfection to this theory."

250. In the "Suite des notices sur les fonctions elliptiques," dated July 21, 1828 (*Crelle*, vol. iii.), Jacobi introduces his functions Θ and H as independent fundamental functions on which to base the theory of elliptic transcendents; a conception to which also Abel was simultaneously led, and which he gave utterance to in writing to Legendre, Nov. 25, 1828:—"The theory of elliptic functions has led me to consider two new functions which enjoy several remarkable properties." Abel desired, quite in analogy with Jacobi's principle, to treat of the properties of these new transcend-

ents apart from the inverse function of the elliptic integral, but the priority of publication of this discovery is Jacobi's, since the completion of the second part of the "Précis d'une théorie des fonctions elliptiques," which was to contain all these investigations, was interrupted by Abel's unexpected death.

The above-mentioned work by Jacobi next contains the theorems expressing elliptic integrals of second and third kinds by θ functions. Regarding the formula of reduction of the integral of the third kind by aid of the θ functions, Jacobi remarks a characteristic property to Legendre (September 9, 1828): "Moreover it shows that elliptic functions of the third kind into which three variables enter reduce to other transcendents which contain only two,"—a discovery which Legendre was greatly interested in, though he found difficulties in the distinction of real and imaginary parameters, expecting that the introduction of an imaginary parameter involved three independent quantities in the integral, and so there should be four kinds of elliptic functions instead of three.

Jacobi, however, repeats the above assertion in his demonstration of the relation $\Pi(u, a) = u\mathrm{Z}(a) + \frac{1}{2}\log\frac{\Theta(u-a)}{\Theta(u+a)}$ (*Crelle*, iv.): "This latter formula shows that elliptic functions of the third kind which depend on three elements can be reduced to other transcendents which contain only two." Later, Jacobi wrote to Legendre (May 23, 1829): "As regards elliptic integrals of the third kind with circular parameter, they do not admit of a reduction analogous to that of the logarithmic kind. In a general analytical sense not distinguishing between real and imaginary values, a formula embraces all cases; but in applying to numerical calculation cases must be distinguished." And again, "as to the numerical calculation of elliptic integrals of the third kind with circular parameter, I do not think you should too much regret the inconvenience that they cannot be reduced to tables of double entry."

251. The collected statement of his investigations, published by Jacobi as his *Fundamenta nova Theoriæ Functionum Ellipticarum* in 1829, contains two main divisions, the first on the transformation of elliptic functions, the second on their evolution. We have already indicated many of the principles contained in this work, the most important of all being that of the double periodicity of these functions. As Jacobi says (*Works*, i. p. 262)—"Elliptic functions differ essentially from ordinary transcendents. They have, so to say, an absolute manner of existence. Their principal character is to embrace all there is in analysis that is periodical. In fact, trigonometric functions having a real period, exponentials an imaginary period, elliptic functions embrace the two cases, since we have at the same time $\sin\mathrm{am}\,(u + 4\mathrm{K}) = \sin\mathrm{am}\,u$, $\sin\mathrm{am}\,(u + 2i\mathrm{K}') = \sin\mathrm{am}\,u$. Moreover it is easily demonstrated that an analytic function cannot have more than two periods, one real and the other imaginary, or both imaginary (complex) if the modulus k be so too. The quotient $\frac{\mathrm{K}'}{\mathrm{K}}$ of the periods of a proposed function determines the modulus of the elliptic functions by which it must be expressed by means of the relations

$$\sqrt{\frac{2\mathrm{K}}{\pi}} = \Theta\left(\frac{\pi}{2}\right),\quad \sqrt{\frac{2k'\mathrm{K}}{\pi}} = \Theta(0),\quad \sqrt{\frac{2k\mathrm{K}}{\pi}} = \mathrm{H}\left(\frac{\pi}{2}\right),$$

(the expansions for which in terms of q follow by § 258). Perhaps it will be convenient to introduce this quotient $\frac{\mathrm{K}'}{\mathrm{K}}$ into analysis as modulus in place of k." On these principles Jacobi subsequently founded a theory of hyperelliptic functions.

252. Jacobi's first evolution of elliptic functions is into infinite products, and is derived from the transformation from λ to k, which is expressed by $\sin\mathrm{am}(nu, k)$

$$= \sqrt{\frac{\lambda^n}{k}}\sin\mathrm{am}\,\frac{u}{\mathrm{M}}\sin\mathrm{am}\left(\frac{u}{\mathrm{M}} + \frac{4i\Lambda'}{n}\right)$$

$$\sin\mathrm{am}\left(\frac{u}{\mathrm{M}} + \frac{8i\Lambda'}{n}\right)\ldots$$

$\sin\mathrm{am}\left(\frac{u}{\mathrm{M}} + \frac{4(n-1)\Lambda'}{n}\right)$, and equivalent forms, by writing in the equations of transformation, for u, $\frac{u}{n}$, and allowing n to take an infinitely great value. When this is done, $\mathrm{am}\left(\frac{u}{\mathrm{M}}, \lambda\right)$ becomes $\mathrm{am}\left(\frac{u}{n\mathrm{M}}, \lambda\right) = \frac{\pi u}{2k} = x$, and he arrives at the equations

$$\sin\mathrm{am}\,\frac{2\mathrm{K}x}{\pi}$$

$$= \frac{2q^{\frac{1}{4}}}{\sqrt{k}}\sin x\,\frac{(1-2q^2\cos 2x + q^4)(1-2q^4\cos 2x + q^8)\ldots}{(1-2q\cos 2x + q^2)(1-2q^3\cos 2x + q^6)\ldots},$$

$$\cos\mathrm{am}\,\frac{2\mathrm{K}x}{\pi}$$

$$= 2q^{\frac{1}{4}}\sqrt{\frac{k'}{k}}\cos x\,\frac{(1+2q^2\cos 2x + q^4)(1+2q^4\cos 2x + q^8)\ldots}{(1-2q\cos 2x + q^2)(1-2q^3\cos 2x + q^6)\ldots}\text{(A)},$$

$$\Delta\,\mathrm{am}\,\frac{2\mathrm{K}x}{\pi}$$

$$= \sqrt{k'}\,\frac{(1+2q\cos 2x + q^2)(1+2q^3\cos 2x + q^6)\ldots}{(1-2q\cos 2x + q^2)(1-2q^3\cos 2x + q^6)\ldots},$$

from which are easily derived such series as

$$\frac{2k\mathrm{K}}{\pi}\sin\mathrm{am}\,\frac{2\mathrm{K}x}{\pi} = \frac{4\sqrt{q}\sin x}{1-q} + \frac{4\sqrt{q^3}\sin 3x}{1-q^3}$$

$$+ \frac{4\sqrt{q^5}\sin 5x}{1-q^5} + \text{etc.}$$

$$= 4\sin x$$

$$\left\{\frac{\sqrt{q}(1+q)}{1-2q\cos 2x + q^2} + \frac{\sqrt{q^3}(1+q^3)}{1-2q^3\cos 2x + q^6} + \text{etc.}\right\}.$$

The series for powers of these functions are then investigated; and it is found, *e.g.*, that the square may be written

$$\left(\frac{2k\mathrm{K}}{\pi}\right)^2\sin^2\mathrm{am}\,\frac{2\mathrm{K}x}{\pi}$$

$$= \frac{4\mathrm{K}(\mathrm{K}-\mathrm{E}^1)}{\pi^2} - 4\left\{\frac{2q\cos 2x}{1-q^2} + \frac{4q^2\cos 4x}{1-q^4} + \frac{6q^3\cos 6x}{1-q^6} + \right\}.$$

253. This enables the second kind of elliptic integral to be evolved in a series. The form introduced being called Z is related to Legendre's E by the equations

$$\frac{2\mathrm{K}x}{\pi} = u,\ \phi = \mathrm{am}\,u,\ \mathrm{Z}(u) = \frac{\mathrm{F}^1\mathrm{E}(\phi) - \mathrm{E}^1\mathrm{F}(\phi)}{\mathrm{F}^1},$$

and the expansion is found

$$\frac{2\mathrm{K}}{\pi}\mathrm{Z}\left(\frac{2\mathrm{K}x}{\pi}\right) = \frac{2\mathrm{K}x}{\pi}\left(\frac{2\mathrm{K}}{\pi} - \frac{2\mathrm{E}^1}{\pi}\right)$$

$$-\left(\frac{2k\mathrm{K}}{\pi}\right)^2\int_0^x \sin^2\mathrm{am}\,\frac{2\mathrm{K}x}{\pi}\,dx \quad .\ .\ .\ .\ \text{(B)}$$

$$= 4\left\{\frac{q\sin 2x}{1-q^2} + \frac{q^2\sin 4x}{1-q^4} + \frac{q^3\sin 6x}{1-q^6} + \right\}.$$

254. Before proceeding to the serial development of the third kind of integrals, the theorems concerning their reduction to depend on functions containing only two variables are given. It is shown first assuming two angles σ, δ, such that $\mathrm{F}(\phi) + \mathrm{F}(\alpha) = \mathrm{F}(\sigma)$ and $\mathrm{F}(\phi) - \mathrm{F}(\alpha) = \mathrm{F}(\delta)$ that

$$\int_0^\phi \frac{k^2\sin\alpha\cos\alpha\,\Delta\alpha\,.\,\sin^2\phi\,d\phi}{\{1-k^2\sin^2\alpha\,.\,\sin^2\phi\}\,\Delta(\phi)}$$

$$= \mathrm{F}(\phi)\mathrm{E}(\alpha) - \tfrac{1}{2}\int_0^\sigma \frac{\mathrm{E}(\phi)d\phi}{\Delta(\phi)} + \tfrac{1}{2}\int_0^\delta \frac{\mathrm{E}(\phi)d\phi}{\Delta(\phi)} \quad .\ .\ \text{(C)};$$

so that the third kind of elliptic integrals, which involves three elements, the modulus k, the amplitude ϕ, and the parameter α (the quantity $-k^2\sin^2\alpha$ is what Legendre called n the parameter, § 206) is reduced to integrals of the first and second kind, and to the new transcendent $\int_0^\phi \frac{\mathrm{E}(\phi)d\phi}{\Delta(\phi)}$, each of these depending only on two elements.

This new transcendent we see from the above equation, by letting $\mathrm{F}(\alpha_2) = 2\mathrm{F}(\alpha)$, and so $\sigma = \alpha_2$, $\delta = 0$, for $\phi = \alpha$, satisfies the equation

$$\int_0^\alpha \frac{k^2\sin\alpha\cos\alpha\,\Delta\alpha\,.\,\sin^2\phi d\phi}{(1-k^2\sin^2\alpha\sin^2\phi)\Delta(\phi)}$$

$$= \mathrm{F}(\alpha)\mathrm{E}(\alpha) - \tfrac{1}{2}\int_0^{\alpha_2}\frac{\mathrm{E}(\phi)d\phi}{\Delta(\phi)};$$

that is to say, for the new transcendent we may substitute the *definite* integral of the third kind in which the amplitude is equal to the parameter; another statement of the reducibility to functions depending on two elements only.

The above equation (C) may be transformed by the identity derived from the formulæ of § 207,

$$\sin^2\sigma - \sin^2\delta = \frac{4\sin\alpha\cos\alpha\,\Delta\alpha\sin\phi\cos\phi\,\Delta\phi}{(1-k^2\sin^2\alpha\sin^2\phi)^2},$$

which gives, on introducing am u for ϕ, am a for α, and consequently am $(u+a)$ for σ and am $(u-a)$ for δ, and integrating,

$$\int_0^u du\left\{\sin^2\text{am}(u+a)-\sin^2\text{am}(u-a)\right\}$$

$$=\frac{2\sin\text{am}\,a\cos\text{am}\,a\,\Delta\,\text{am}\,a\,.\,\sin^2\text{am}\,u}{1-k^2\sin^2\text{am}\,a\,.\,\sin^2\text{am}\,u}.$$

255. Jacobi accordingly accepts as canonical for an integral of the third kind the form written above. He defines it by

$$\Pi(u,\,a)=\int_0^u\frac{k^2\sin\text{am}\,a\,.\cos\text{am}\,a\,.\,\Delta\,\text{am}\,a\,.\,\sin^2\text{am}\,u\,.\,du}{1-k^2\sin^2\text{am}\,a\,.\,\sin^2\text{am}\,u}.$$

Again, denoting by $\Theta(u)$ the expression

$\Theta(u)=\Theta(0)e^{\int_0^u Z(u)du}$, the integration of the series for $Z(u)$ (§ 253) gives

$$\frac{2K}{\pi}\int_0^x Z\left(\frac{2Kx}{\pi}\right)dx$$

$$=-2\left\{\frac{q\cos 2x}{1-q^2}+\frac{q^2\cos 4x}{2(1-q^4)}+\frac{q^3\cos 6x}{3(1-q^6)}+\text{etc.}\right\}+\text{const.}$$

$=\log$

$$\left\{\frac{(1-2q\cos 2x+q^2)(1-2q^3\cos 2x+q^6)(1-2q^5\cos 2x+q^{10})\ldots}{\{(1-q)(1-q^3)(1-q^5)\ \ldots\ \}^2}\right\};$$

whence

$$\frac{\Theta\left(\frac{2Kx}{\pi}\right)}{\Theta(0)}=\frac{(1-2q\cos 2x+q^2)(1-2q^3\cos 2x+q^6)\ \ldots}{\{(1-q)(1-q^3)(1-q^5)\ \ldots\}^2}.$$

256. This is the first introduction in the *Fundamenta* of these functions, which have been called *theta* functions from the original notation adopted for them by Jacobi, and by many writers have been named after him *Jacobian functions.*

The connection of the integral of the third kind with these functions follows at once from § 254. In fact, calling $\frac{d\Theta(u)}{du}=\Theta'(u)$, it is

$$\Pi(u,\,a)=uZ(a)+\tfrac{1}{2}\log\frac{\Theta(u-a)}{\Theta(u+a)}=u\frac{\Theta'(a)}{\Theta(a)}+\tfrac{1}{2}\log\frac{\Theta(u-a)}{\Theta(u+a)}.$$

But since Θ is an even function in u, $\Theta(u)=\Theta(-u)$,

whence $$\Pi(a,\,u)=aZ(u)+\tfrac{1}{2}\log\frac{\Theta(u-a)}{\Theta(u+a)}.$$

Hence, subtracting,

$$\Pi(u,\,a)-\Pi(a,\,u)=uZ(a)-aZ(u),$$

which is in this notation the theorem that an integral of the third kind can always be reduced to another in which its parameter and amplitude are interchanged, as was noticed by Legendre (§ 216).

The development of $\Pi(u)$ in a series is found by aid of the series for $\sin^2$am u and of the last equation in § 254. It is

$$\Pi\left(\frac{2Kx}{\pi},\,\frac{2KA}{\pi}\right)=\frac{2Kx}{\pi}Z\left(\frac{2KA}{\pi}\right)$$

$$-2\left\{\frac{q\sin 2A\sin 2x}{1-q^2}+\frac{q^2\sin 4A\sin 4x}{2(1-q^4)}\right.$$

$$\left.+\frac{q^3\sin 6A\sin 6x}{3(1-q^6)}+\text{etc.}\right\}.$$

257. Returning from the integrals to the elliptic functions, the expressions in infinite products (A, § 252) are resumed. The occurrence of the function Θ is apparent in each of the denominators. Introducing the definition of a function H,

$$\frac{H\left(\frac{2Kx}{\pi}\right)}{\Theta(0)}$$

$$=\frac{2q^{\frac{1}{4}}\sin x(1-2q^2\cos 2x+q^4)(1-2q^4\cos 2x+q^8)\ \ldots}{\{(1-q)(1-q^3)(1-q^5)\ \ldots\ \}^2},$$

and replacing $\frac{2Kx}{\pi}$ by u, it is easily seen that the expressions are

$$\sin\text{am}\,u=\frac{1}{\sqrt{k}}\,\frac{H(u)}{\Theta(u)},\ \cos\text{am}\,u=\sqrt{\frac{k'}{k}}\,\frac{H(u+K)}{\Theta(u)},$$

$$\Delta\,\text{am}\,u=\sqrt{k'}\frac{\Theta(u+K)}{\Theta(u)}.$$

Again, it is easily seen that $\Theta(u+2K)=\Theta(u)$ and $H(u+2K)=-H(u)$. Also as by substituting iu for u (§ 235) we get

$$iZ(iu,\,k)=Z(u,\,k')+\frac{\pi u}{2KK'}-\tan\text{am}(u,\,k')\Delta\text{am}(u,\,k');$$

whence, integrating,

$$\frac{\Theta(iu,\,k)}{\Theta(0,\,k)}=e^{\frac{\pi u^2}{4KK'}}\cos\text{am}(u,\,k')\frac{\Theta(u,\,k')}{\Theta(0,\,k')},$$

it follows that $$\Theta\,(u+2iK')=-e^{\frac{\pi(K'-iu)}{K}}\Theta(u);$$

as also that $\Theta(u+iK')=ie^{\frac{\pi(K'-2iu)}{4K}}\Theta(u)\,.\,\sqrt{k}\sin\text{am}\,u\,.$

whence $$=ie^{\frac{\pi(K'-2iu)}{4K}}H(u);$$

and by successively replacing u by $u+iK'$ it is hence seen that $\Theta(u)$ and $H(u)$ have one real period 4K common with the elliptic functions, and that $e^{\frac{\pi u^2}{4KK'}}\Theta(u)$ and $e^{\frac{\pi u^2}{4KK'}}H(u)$ have another imaginary period $4iK'$ in common with them.

258. The expansion of the Θ and H functions in series of cosines and sines of multiple arcs by the method of indeterminate coefficients determines

$$\Theta\left(\frac{2Kx}{\pi}\right)=1-2q\cos 2x+2q^4\cos 4x-2q^9\cos 6x+2q^{16}\cos 8x-,$$

$$H\left(\frac{2Kx}{\pi}\right)=2q^{\frac{1}{4}}\sin x-2q^{\frac{9}{4}}\sin 3x+2q^{\frac{25}{4}}\sin 5x-2q^{\frac{49}{4}}\sin 7x+;$$

and hence a new development of elliptic functions as well as of the integrals arises.

The developments of the numerators of the cos am and Δ am may be written down from the above—in the notation subsequently used by Jacobi—

$$\theta x=1-2q\cos 2x+2q^4\cos 4x-2q^9\cos 6x+\ \ldots$$

$$\theta_1 x=2q^{\frac{1}{4}}\sin x-2q^{\frac{9}{4}}\sin 3x+2q^{\frac{25}{4}}\sin 5x-\ \ldots$$

$$\theta_2 x=2q^{\frac{1}{4}}\cos x+2q^{\frac{9}{4}}\cos 3x+2q^{\frac{25}{4}}\cos 5x+\ \ldots$$

$$\theta_3 x=1+2q\cos 2x+2q^4\cos 4x+2q^9\cos 6x+\ \ldots$$

as, for instance, in his lectures, in which, without any presupposition from the theory of elliptic transcendents, he established the relations which these series fulfil, and from them a theorem of addition for the quotients of the series, and from this the differential formulæ which lead immediately to the elliptic integrals. All these formulæ consist of series of exponential quantities, extending in both directions to infinity, in which the ordering element in the exponent rises to the second degree. Their general form may therefore be written $\Sigma e^{a\nu^2+2b\nu+c}$, where ν takes all positive and negative integer values.

259. The *Fundamenta Nova* appeared almost at the date of the death of Abel. Of Abel's works, besides those which we have mentioned, the chief is the unfinished "Précis d'une théorie des fonctions elliptiques," which appeared in *Crelle*, iv., in 1829. "The whole of my researches will form a work of some extent which I cannot yet publish, therefore I give here a 'Précis' of the method I followed, and its general results." The fragment of this work which has been published deals only with the integrals.

260. The consideration of the indeterminateness of the integral

$$u=\int_0^x\frac{dx}{\sqrt{(1+x^2)(1-k^2x^2)}},$$

which gives rise to periodicity in the inverse function $x=\sin\text{am}\,u$, has led to the consideration of the whole subject from a new point of view. The introduction of the *complex variable* into analysis by Cauchy in his *Mémoire sur les intégrales définies prises entre des limites imaginaires* (1825), and by Gauss in the second part of his *Theoria Residuorum Biquadraticorum* (1831), has been followed by the works of Puiseux ("Recherches sur les fonctions algébriques," *Liouville*, xv. 1850), of Riemann (*Inaugural Dissertation*, 1851, and "Theorie der Abelschen Functionen," *Crelle*, 1857), and of Weierstrass ("Theorie der Abelschen Functionen," *Crelle*, 1856)—which develop the subject in this more extended field, perfecting the conception which the term *function* covers in analysis, and pointing out the essential distinctions in the different modes of dependence of two quantities,—such distinctions, for instance, as when a function is defined by a differential equation, whether it is one-valued or not, and, if it be, whether it is integer or fractional.

261. In close connection with this is another department to which the theory of transcendents has with great success been applied,—the investigation of the geometrical properties of curves. The points on a curve are expressed as functions of a parameter, and on the nature of these functions the nature of the curve depends,—the "deficiency" or "Geschlecht" of the curve (see CURVE, vol. vi., p. 640) determines the nature of the function, and any curve into which another can be rationally transformed depends on the same function.

We shall conclude with a brief application to the case of elliptic functions and plane curves of the third degree. It is well known that the equation of any non-singular cubic can be reduced to the form

$$yz^2 = x(x-y)(x-k^2y) \ ,$$

where $y=0$ is the tangent at the point of inflexion in which the curve meets $x=0$, and $x=0$, $x=y$, $x=k^2y$ are the tangents from that point to the curve, their points of contact lying on $z=0$.

This equation is satisfied identically by assuming the equations $\rho x = \sin\text{am}\, u$, $\rho y = \sin^3\text{am}\, u$, $\rho z = \Delta\text{am}\, u \cos\text{am}\, u$, which determine any point on the curve by a parameter u. To each value of u corresponds a perfectly definite point of the curve. But on the other hand, to any point of the curve corresponds an infinite number of values of the argument all related to one of them, u,—differing from it only by a multiple sum of the periods.

The occurrence of the elliptic integral u here in this normal form results from the co-ordinates chosen; but, whatever they be, we see that the points of the curve can be expressed by a parameter depending on no higher irrationality than that we have introduced. When the cubic has a double point, the co-ordinates of any point on the curve can be expressed by a parameter without introducing any irrationality.

262. To investigate the intersections of the cubic with a right line we proceed to derive in a simple manner a slight extension of Euler's integral (§ 207). Written in Jacobi's notation it is

$$\begin{aligned}\cos\text{am}(u_1+u_2) &= \cos\text{am}\, u_1 \cos\text{am}\, u_2 \\ &\quad - \sin\text{am}\, u_1 \sin\text{am}\, u_2\, \Delta\text{am}(u_1+u_2),\end{aligned}$$

which is easily thrown into the form

$$\begin{aligned}k'^2 + k^2 \cos\text{am}\, u_1 \cos\text{am}\, u_2 \cos\text{am}(u_1+u_2) \\ = \Delta\text{am}\, u_1\, \Delta\text{am}\, u_2\, \Delta\text{am}(u_1+u_2) \ .\end{aligned}$$

This may be extended to three arguments as follows. Denoting $\sin\text{am}\, u_r$ briefly by s_r, also $\cos\text{am}\, u_r$ by c_r, $\Delta\text{am}\, u_r$ by Δ_r, $\tan\text{am}\, u_r$ by t_r, and $\cot\text{am}\, u_r$ by ct_r, the formula may be written

$$k'^2 + k^2\, c_1c_2c(u_1+u_2) = \Delta_1\Delta_2\Delta(u_1+u_2) \ ;$$

putting for u_2, u_2+u_3, and expressing, by § 207, $c(u_2+u_3)$ and $\Delta(u_2+u_3)$ by functions of one argument, we get

$$\begin{aligned}&k'^2 + k^2c_1c_2c_3c(u_1+u_2+u_3) - \Delta_1\Delta_2\Delta_3\Delta(u_1+u_2+u_3) \\ &= k^2s_2s_3\left\{k'^2s_2s_3 + c_1\Delta_2\Delta_3c(u_1+u_2+u_3) - \Delta_1c_2c_3\Delta(u_1+u_2+u_3)\right\}.\end{aligned}$$

Now the former expression is symmetrical; denoting it by $k^2s_1s_2s_3\theta$, we can determine θ as follows. Writing for brevity

$$c(u_1+u_2+u_3) = \text{C}, \text{ and } \Delta(u_1+u_2+u_3) = \Delta \ ,$$

the equation is $\quad k'^2s_2s_3 + c_1\Delta_2\Delta_3\text{C} - \Delta_1c_2c_3\Delta - \theta s_1 = 0$.

Hence writing down the three equations, which must hold from symmetry,

$$\begin{aligned}0 &= k'^2s_2s_3 + c_1\Delta_2\Delta_3\text{C} - \Delta_1c_2c_3\Delta - \theta s_1 \ , \\ 0 &= k'^2s_3s_1 + c_2\Delta_3\Delta_1\text{C} - \Delta_2c_3c_1\Delta - \theta s_2 \ , \\ 0 &= k'^2s_1s_2 + c_3\Delta_1\Delta_2\text{C} - \Delta_3c_1c_2\Delta - \theta s_3 \ ,\end{aligned}$$

we obtain C and Δ as quotients of determinants of single arguments. For Δ we get

$$\begin{vmatrix} 1 & s_1^2 & s_1c_1\Delta_1 \\ 1 & s_2^2 & s_2c_2\Delta_2 \\ 1 & s_3^2 & s_3c_3\Delta_3 \end{vmatrix} \Delta = \begin{vmatrix} 1 & s_1^2 & \dfrac{s_1c_1}{\Delta_1} \\ 1 & s_2^2 & \dfrac{s_2c_2}{\Delta_2} \\ 1 & s_3^2 & \dfrac{s_3c_3}{\Delta_3} \end{vmatrix} \Delta_1\Delta_2\Delta_3 \ ,$$

and for C

$$\begin{vmatrix} 1 & s_1^2 & s_1c_1\Delta_1 \\ 1 & s_2^2 & s_2c_2\Delta_2 \\ 1 & s_3^2 & s_3c_3\Delta_3 \end{vmatrix} \text{C} = \begin{vmatrix} 1 & s_1^2 & \Delta_1t_1 \\ 1 & s_2^2 & \Delta_2t_2 \\ 1 & s_3^2 & \Delta_3t_3 \end{vmatrix} c_1c_2c_3.$$

But in this, increasing each argument by $i\text{K}'$, since then we get, for s_r, $\dfrac{1}{ks_r}$, for c_r, $\dfrac{-i\Delta_r}{ks_r}$, for Δ_r, $-ict_r$, for t_r, $\dfrac{i}{\Delta_r}$, and thus for C, $\dfrac{i\Delta}{k\text{S}}$, where S stands for $\sin\text{am}(u_1+u_2+u_3)$, this formula gives

$$\frac{\Delta}{\Delta_1\Delta_2\Delta_3}\begin{vmatrix} 1 & s_1^2 & \Delta_1ct_1 \\ 1 & s_2^2 & \Delta_2ct_2 \\ 1 & s_3^2 & \Delta_3ct_3 \end{vmatrix} = -\begin{vmatrix} 1 & s_1^2 & \dfrac{c_1s_1}{\Delta_1} \\ 1 & s_2^2 & \dfrac{c_2s_2}{\Delta_2} \\ 1 & s_3^2 & \dfrac{c_3s_3}{\Delta_3} \end{vmatrix} \frac{\text{S}}{s_1s_2s_3};$$

whence

$$\sin\text{am}(u_1+u_2+u_3) = -\frac{\begin{vmatrix} s_1 & s_1^3 & \Delta_1c_1 \\ s_2 & s_2^3 & \Delta_2c_2 \\ s_3 & s_3^3 & \Delta_3c_3 \end{vmatrix}}{\begin{vmatrix} 1 & s_1^2 & s_1c_1\Delta_1 \\ 1 & s_2^2 & s_2c_2\Delta_2 \\ 1 & s_3^2 & s_3c_3\Delta_3 \end{vmatrix}};$$

and the value for θ thus found gives

$$\begin{aligned}k'^2 + k^2c_1c_2c_3\text{C}(u_1+u_2+u_3) - \Delta_1\Delta_2\Delta_3\Delta(u_1+u_2+u_3) \\ + k^2k'^2s_1s_2s_3\text{S}(u_1+u_2+u_3) = 0.\end{aligned}$$

263. The formula thus obtained for $\sin\text{am}(u_1+u_2+u_3)$ vanishes when $u_1+u_2+u_3=0$, or differs from 0 only by an integer combination of the periods. But the determinant

$$\begin{vmatrix} s_1 & s_1^3 & \Delta_1c_1 \\ s_2 & s_2^3 & \Delta_2c_2 \\ s_3 & s_3^3 & \Delta_3c_3 \end{vmatrix}$$

vanishes if its constituents be the co-ordinates of three collinear points. But these are, as we have just seen, the co-ordinates of three points on the cubic $yz^2 = x(x-y)(x-k^2y)$, § 261.

This result may therefore be stated thus:—*If the points of a cubic be expressed as elliptic functions of a parameter, then for the intersections with a right line the sum of the arguments differs from zero only by some integer combination of the periods.*

This enables us to solve many problems. For instance, the arguments of the points of contact of the four tangents which can be drawn to the curve from a point u on it are

$$-\frac{u}{2}, -\frac{u+\omega}{2}, -\frac{u+\omega'}{2}, \ \frac{u+\omega+\omega'}{2}.$$

Conversely the tangential point u of a given point v of the curve is determined by $u \equiv -2v \pmod{\omega, \omega'}$.

The problem of determination of points of inflexion when one point of inflexion is known is identical with the problem of the special trisection of elliptic functions, *i.e.*, of the determination of the values for $u \equiv \dfrac{p\omega + q\omega'}{3}$ to the same moduli.

Bibliography.—In addition to the works on elliptic functions and the higher transcendents already named, there have recently appeared as independent works, besides innumerable memoirs in the various mathematical periodicals—Briot and Bouquet, *Théorie des fonctions elliptiques*, 2d ed., 1875; Briot, *Théorie des fonctions abéliennes*, 1879; Booth, *Theory of Elliptic Integrals*, 1851; Casorati, *Teorica delle funzioni di variabili complesse*, 1868; Cayley, *Elementary Treatise on Elliptic Functions*, 1876; Clebsch, *Geometrie*, 1876; Clebsch and Gordan, *Theorie der Abelschen Functionen*, 1866; Durège, *Elemente der Theorie der Functionen*, 1873; Id., *Theorie der ellipt. Funct.*, 1878; Eisenstein, "Beiträge," collected in his *Math. Abhandlungen*, 1847; Ellis, "Report on Recent Progress of Analysis," *Brit. Ass. Reports*, 1846; Enneper, *Ell. Funct. Theorie und Geschichte*, 1876; Königsberger, *Transformation, etc., der Ell. Functionen*, 1868; Id., *Theorie d. Ell. Funct.*, 1874; Id., *Theorie d. hyperelliptischen Integrale*, 1878; Id., *Geschichte der Ell. Transcendenten*, 1879 (to the last two authors we are mainly indebted for the historical details of our subject); Lipschitz, *Differential und Integralrechnung*, 1880; Neumann, *Ueber Riemann's Theorie d. Abelschen Integrale*, 1865; Roberts, *On Addition of Elliptic and Hyperelliptic Integrals*, 1871; Russell, "Report on Recent Progress in Elliptic and Hyperelliptic Functions," *Brit. Ass. Reports* (1869, p. 334; 1870, p. 102; 1872, p. 335; 1873, p. 307); Schellbach, *Ell. Integralen und Theta Functionen*, 1864; Schlömilch, *Compendium der Höheren Analysis*, 2d ed., 1874; Sohncke, "Elliptische Functionen," in Ersch and Gruber's *Encyclopädie*; Thomæ, *Abriss einer Theorie der complexen Functionen*, 1873; Id., *Sammlung von Formeln*, 1876; Verhulst, *Traité élémentaire des fonctions elliptiques*, 1841; Weber, *Theorie d. Abelschen Functionen, vom Geschlecht 3*, 1876; Weyr, *Theorie d. Ell. Funct.*, 1876; and of the highest historical interest is the publication by Borchardt of the correspondence between Legendre and Jacobi in vol. lxxx. of *Crelle's Journal*, 1875, reproduced in vol. i. of the collected works of Jacobi, 1881. (B. W.)

INFLUENZA (syn. Epidemic Catarrh) is a term applied to an infectious febrile disorder of short duration, characterized specially by catarrh of the respiratory passages and alimentary canal, and occurring mostly as an epidemic.

The symptoms of this disease develop suddenly, with all the phenomena attending a severe cold or catarrh. At first there are chills or rigors, which are soon accompanied with distressing headache and tightness across the forehead, tenderness and watering of the eyes, and sneezing and discharge from the nostrils. To these succeed heat and soreness of the throat, hoarseness, cough, and, it may be, some difficulty of breathing. The temperature is elevated, the pulse quick and feeble, and the skin, which at first was dry, becomes moist, and is said to exhale a peculiar musty odor. The digestive system participates in the disturbance, and there is loss of appetite, with thirst, vomiting, and occasionally diarrhœa.

Rapid loss of strength and remarkable depression of spirits accompany these various symptoms, and are among the most characteristic features of the disease. After lasting for two or three days, the symptoms abate and convalescence begins, but there may remain, particularly in severe cases, and in persons at the extremes of life, great debility for a length of time, or the attack may be complicated with inflammatory affections of the chest, which may prove a source of danger far exceeding that of the original disease. Apart from this, influenza is not usually a very fatal malady, although some epidemics such as that of 1762 have been characterized by a severe type of the disease and considerable loss of life. The mortality is generally reckoned at about 2 per cent., but when an extensive epidemic prevails, even this proportion is sufficient to swell the death-rate largely.

This disease is referred to in the works of the ancient physicians; but accurate descriptions of it have been given by numerous medical writers during the last three centuries, in connection with epidemics which have occurred from time to time. These various accounts agree substantially in their narration of the phenomena and course of the disease, and influenza has in all times been regarded as fulfilling all the conditions of an epidemic in its sudden invasion, rapid and extensive spread, and speedy and complete disappearance. Among the chief epidemics of influenza are those of 1762, 1782, 1787, 1803, 1833, 1837, and 1847. In several of these the disease appeared to originate in some parts of Asia, and to travel westward through Europe and on to America, resembling in this respect certain cholera epidemics, although the two classes of disease have nothing in common. In some of the epidemics influenza has spread through the whole of Europe in the course of six weeks. Wherever it appears the whole community suffers to a greater or less extent, irrespective of age or condition of life. It has occasionally appeared in fleets at sea away from all communication with land, and to such an extent as to disable them temporarily for service. This happened in 1782 in the case of the squadron of Admiral Kempenfelt, which had to return to England from the coast of France in consequence of a severe epidemic of influenza attacking his crews, while at the same time the squadron of Lord Anson, off the coast of Holland, suffered extensively from a similar outbreak. Many instances of a like kind have been recorded.

Much speculation and some amount of scientific inquiry have been expended in endeavors to ascertain the cause of this remarkable ailment. The Italians in the 17th century ascribed it to the influence of the stars, and hence the name "influenza," by which the disease has subsequently been known. By some it has been held to depend on certain telluric, and by others on certain climatic conditions; but the occurrence of the disease in all sorts of climates and localities is sufficient to negative these theories. The view which refers it to some morbific principle present in the atmosphere during an epidemic is that which has gained widest acceptance, but the nature of this infecting agent is unknown. Various hypotheses have been advanced on the subject, such as some change in the electrical condition of the air, or the over-abundance of ozone, but these have not been confirmed by observation. More probable, and more in harmony with observed facts, is the theory that in influenza, as in other epidemic diseases, there is present in the atmosphere some minute organism of specific nature, which is not only distributed over wide areas, but which when introduced into the bodies of those attacked multiplies there indefinitely, and becomes a source of infection by the breath, etc., and in this way a further cause of the spread of the disease. The contagiousness of influenza appears to be unquestionable. The treatment of this disorder is similar to that recommended in CATARRH (*q. v.*), but special regard must be had to its weakening effects, and every effort made throughout the illness to maintain the strength by light but nutritious diet.

(J. O. A.)

INFORMATION, in English law, is a formal accusation of a crime committed, preferred *ex officio* by the attorney-general or solicitor-general in the Queen's Bench without the intervention of a grand jury. It lies only for misdemeanor and not for treason, felonies, or misprision of treason (see INDICTMENT); and it is properly employed against such "enormous misdemeanors" as peculiarly tend to disturb or endanger the Queen's government, *e. g.*, seditions, obstructing the Queen's officers in the execution of their duties, etc. In the form of the proceedings the attorney-general is said to "come into the court of our lady the Queen before the Queen herself at Westminster, and gives the court there to understand and be informed that, etc." Then follows the statement of the offence as in an indictment. The information is filed in the crown office without the leave of the court. An information may also be filed at the instance of a private prosecutor for misdemeanors not affecting the government, but being peculiarly flagrant and pernicious. Thus criminal informations have been granted for bribing or attempting to bribe public functionaries, and for aggravated libels on public or private persons. Leave to file an information is obtained after an application to show cause, founded on a sworn statement of the material facts of the case.

INFUSORIA. See PROTOZOA.

INGELHEIM. Oberingelheim and Niederingelheim, two contiguous market-towns of Germany, in the Hessian province of Rhine Hesse, circle of Bingen, are situated on the Hessian Ludwig Railway and on the Salz near its confluence with the Rhine, 9 miles west-north-west of Mainz. Oberingelheim, formerly an imperial village, has an old Evangelical church with painted windows representing scenes in the life of Charlemagne, a Catholic church, and a synagogue. Its industries are the manufacture of wine and paper-making. The population of Oberingelheim in 1875 was 2846, and of Niederingelheim 2474.

Niederingelheim is, according to one tradition, the birthplace of Charlemagne, and it possesses the ruins of an old palace built by that emperor between 768 and 774. The building contained one hundred marble pillars, and was adorned with sculptures and mosaics from Italy. It was extended by Frederick Barbarossa, and continued to be a favorite residence of the emperors till 1356, when Charles IV. resigned it to the Palatinate. The building suffered much damage during the Bavarian feud of 1504, the Thirty Years' War, and the French invasion in 1689. Only few remains of it are now standing, but some of the pillars are still to be found in different parts of Germany. Inside the boundaries there is an old church, apparently dating from the time of Frederick I. See Hilz, *Der Reichspalast zu Ingelheim*, Oberingelheim, 1868.

INGEMANN, BERNHARD SEVERIN (1789–1862), a Danish poet and novelist, was born at Torkildstrup, in the island of Falster, on the 28th of May, 1789. He lost his father in early childhood, was educated at the grammar school at Slagelse, and entered the university of Copenhagen in 1806. His studies were interrupted by the English invasion, and on the first night of the bombardment of the city Ingemann stood with the young poet Blicher on the walls, while the shells whistled past them, and comrades were killed on either side. All his early and unpublished writings were destroyed by the English when they burned the town. In 1811 he published his first volume of poems, and in 1812 his second, followed in 1813 by a book of lyrics, entitled *Procne*. These three volumes were extremely well received, and so was his cycle of romances in verse, called *The Black Knight*, 1814. With these books he attained at once the leading position in Denmark as a lyrist, and he then turned his attention to the drama. In 1815 he published two tragedies, *Masaniello* and *Blanca*, followed by *The Voice in the Desert*, *The Shepherd of Tolosa*, and other romantic plays. After a variety of publications, all enormously successful, he travelled in 1818 to Italy. At Rome he wrote *The Liberation of Tasso*, and returned in 1819 to Copenhagen. In 1820 he began to display his real power in a volume of delightful tales. In 1821 his dramatic career closed with the production of an unsuccessful comedy, *Magnetism in a Barber Shop*. In 1822 the poet was nominated lector in Danish language and literature at Sörö College, and he now married. *Valdemar the Great and his Men*, an historical epic, appeared in 1824. The next few years were occupied with his best and most durable work, his four great historical novels of *Valdemar Seier*, 1826; *Erik Menved's Childhood*, 1828; *King Erik*, 1833; and *Prince Otto of Denmark*, 1835. He then returned to epic poetry in *Queen Margaret*, 1836, and *Holger Danske*, 1837. The number of his later writings is too great to permit us to chronicle them. They consist of religious and sentimental lyrics, epic poems, novels, short stories in prose, and fairy tales. His last publication was *The Apple of Gold*, 1856. In 1846 Ingemann was nominated director of Sörö College, a post from which he retired in 1849. He died peacefully and happily on the evening of the 24th of February, 1862. Ingemann enjoyed during his lifetime a popularity which was unapproached even by that of Oehlenschläger, and in fact it may be said that no Danish poet has ever been nearly so popular as he. But criticism has been busy since his death in reversing this decision of the public, and Ingemann now takes a place in Danish literature below four or five of his immediate contemporaries. His boundless facility and fecundity, his sentimentality, his religious melancholy, his direct appeal to the domestic affections, gave him instant access to the ear of the public. His novels are better than his poems; of the former the best are those which are directly modelled on the manner of Sir Walter Scott. As a dramatist he has entirely outlived his reputation, and his unwieldy epics are now little read. Ingemann was a purely sentimental writer, and his reputation has proved no less ephemeral than the fashion for sentiment.

INGOLSTADT, a fortified town in the government district of Upper Bavaria, is situated on the left bank of the Danube at its junction with the Schutter, 50 miles north of Munich by rail. As the chief town of the district it is the seat of the usual authorities. The town is well built. The principal buildings are the old castle of the dukes of Bavaria-Ingolstadt, now used as an arsenal; the remains of the earliest Jesuits' college in Germany, founded in 1555; the former university buildings, now a school; the theatre; the large Gothic church of Our Lady, founded in 1425, with two massive towers, and the grave of Dr. Eck, Luther's opponent; the Franciscan convent and nunnery; and several other churches and hospitals. Ingolstadt possesses several technical and other schools. In 1472 a university was founded in the town by Duke Louis the Rich, which at the end of the 16th century was attended by 4000 students. In 1800 it was removed to Landshut, whence it was finally transferred to Munich in 1826. The industries of Ingolstadt comprise brewing, wax-bleaching, and potash-boiling; there is also trade in vegetables. The station, an important junction 1½ miles distant, is connected with the town by tramway. The population in 1875 was 14,485.

Ingolstadt, known as *Aureatum* or *Chrysopolis*, was a royal villa in the beginning of the 9th century, and only received its city charter about 1312, from the emperor Louis of Bavaria. After that date it gradually grew in importance, and became the capital of a mediæval dukedom which merged finally in that of Bavaria-Munich. The fortifications, erected in 1539, were put to the test during the contests of the Smalkaldian League, and in the Thirty Years' War. Gustavus Adolphus besieged Ingolstadt in 1632, when Tilly, to whom there is a monument in the church, lay mortally wounded within the walls. In the war of the Spanish succession it was besieged by the margrave of Baden in 1704. In 1743 it was surrendered by the French to the Austrians, and in 1800, after a three months' siege, the French under General Moreau took the town, and destroyed the fortifications. These, however, were rebuilt on a much larger scale under King Louis I.; and since 1834 Ingolstadt has ranked as a fortress of the first class. In 1872 even more important fortifications were begun, which include têtes-de-pont with round towers of massive masonry, and the Réduit Tilly on the right bank of the river.

INGRES, Jean Auguste Dominique (1780–1867), whose name represents one of the most important among the conflicting tendencies of modern art, was born at Montauban August 29, 1780. His father, for whom he always entertained the most tender and respectful affection, has described himself as *sculpteur en plâtre;* he was, however, equally ready to execute every other kind of decorative work, and now and again eked out his living by taking portraits, or obtained an engagement as a violin player. He brought up his son to command the same varied resources, but in consequence of certain early successes—the lad's performance of a concerto of Viotti's was applauded at the theatre of Toulouse—his attention was directed chiefly to the study of music. At Toulouse, to which place his father had removed from Montauban in 1792, Ingres had, however, received lessons from Joseph Roques, a painter, whom he quitted at the end of a few months to become a pupil of M. Vigan, professor at the academy of fine arts in the same town. From M. Vigan, Ingres, whose vocation became day by day more distinctly evident, passed to M. Briant, a landscape-painter who insisted that his pupil was specially gifted by nature to follow the same line as himself. For a while Ingres obeyed, but he had been thoroughly aroused and enlightened as to his own objects and desires by the sight of a copy of Raphael's Madonna della Sedia, and, having decisively ended his connection with Briant, he started for Paris, where he arrived about the close of 1796. He was then admitted to the studio of David, for whose lofty standard and severe principles he always retained a profound appreciation. David recognized the merit of one who soon ranked amongst his most promising pupils, and Ingres, after four years of devoted study, in the course of which (1800) he obtained the second place in the yearly competition, finally carried off the Grand Prix (1801). The work thus rewarded—the Ambassadors of Agamemnon in the Tent of Achilles (École des Beaux Arts)—was admired by Flaxman so much as to give umbrage to David, and was succeeded in the following year (1802) by the execution of a Girl after Bathing, and a woman's portrait; in 1804 Ingres exhibited Portrait of the First Consul (Musée de Liége), and portraits of his father and himself; these were followed in 1806 by Portrait of the Emperor (Invalides), and portraits of M., Mme., and Mdlle. Rivière (the first two now in the Louvre). All these and various minor works were executed in Paris, for it was not until 1809 that the state of public affairs admitted of the re-establishment of the Academy of France at Rome, and we find from the journals of the day that they produced a disturbing impression on the public. It was clear that the artist was some one who must be counted with; his talent, the purity of his line, and his power of literal rendering were generally acknowledged; but he was reproached with a desire to be singular and extraordinary. "Ingres" writes Frau v. Hastfer (*Leben und Kunst in Paris*, 1806) "wird nach Italien gehen, und dort wird er vielleicht vergessen dass er zu etwas Grossem geboren ist, und wird eben darum ein hohes Ziel erreichen." In this spirit, also, Chaussard violently attacked his Portrait of the emperor (*Pausanias Français*, 1806), nor did the portraits of the Rivière family escape. The points on which Chaussard justly lays stress are the strange discordances of color,—such as the blue of the cushion against which Mme. Rivière leans, and the want of the relief and warmth of life, but he omits to touch on that grasp of his subject as a whole, shown in the portraits of both husband and wife, which already evidences the strength and sincerity of the passionless point of view which marks all Ingres's best productions. The very year after his arrival in Rome (1808) Ingres produced Œdipus and the Sphinx (Louvre; lithographed by Sudre, engraved by Gaillard), a work which proved him in the full possession of his mature powers, and began the Venus Anadyomene (Collection Rieset; engraving begun by Pollet), completed forty years later, and exhibited in 1855. These works were followed by some of his best portraits, that of M. Bochet (Louvre), and that of Mme. la Comtesse de Tournon, mother of the prefect of the department of the Tiber; in 1811 he finished Jupiter and Thetis, an immense canvas now in the Musée of Aix; in 1812 Romulus and Acron (École des Beaux Arts), and Virgil reading the *Æneid*—a composition very different from the version of it which has become widely popular through the engraving executed by Pradier in 1832. The original work, executed for a bedchamber in the Villa Aldobrandini-Miollis, contained neither the figures of Mæcenas and Agrippa nor the statue of Marcellus; and Ingres, who had obtained possession of it during his second stay in Rome, intended to complete it with the additions made for engraving. But he never got beyond the stage of preparation, and the picture left by him, together with various other studies and sketches, to the Musée of his native town, remains half destroyed by the process meant for its regeneration. The Virgil was followed by the Betrothal of Raphael, a small painting, now lost, executed for Queen Caroline of Naples; Don Pedro of Toledo Kissing the Sword of Henry IV. (Collection Deymié; Montauban), exhibited at the Salon of 1814, together with the Chapelle Sistine (Collection Legentil; lithographed by Sudre), and the Grande Odalisque (Collection Seillière; lithographed by Sudre). In 1815 Ingres executed Raphael and the Fornarina (Collection Mme. N. de Rothschild; engraved by Pradier); in 1816 Aretin and the Envoy of Charles V. (Collection Schroth), and Aretin and Tintoret (Collection Schroth); in 1817 the Death of Leonardo (engraved by Richomme) and Henry IV. playing with his Children (engraved by Richomme), both of which works were commissions from M. le Comte de Blacas, then ambassador of France at the Vatican. Roger and Angelique (Louvre; lithographed by Sudre), and Francesca di Rimini (Musée of Angers; lithographed by Aubrey Lecomte), were completed in 1819, and followed in 1820 by Christ giving the Keys to Peter (Louvre). In 1815, also, Ingres had made many projects for treating a subject from the life of the celebrated duke of Alva, a commission from the family, but a loathing for "cet horrible homme" grew upon him, and finally he abandoned the task and entered in his diary—"J'étais forcé par la nécessité de peindre un pareil tableau; Dieu a voulu qu'il restât en ébauche." During all these years Ingres's reputation in France did not increase. The interest which his Chapelle Sistine had aroused at the Salon of 1814 soon died away; not only was the public indifferent, but amongst his brother artists Ingres found scant recognition. The strict classicists looked upon him as a renegade, and strangely enough Delacroix and other pupils of Guérin—the very leaders of that romantic movement for which Ingres, throughout his long life, always expressed the deepest abhorrence—alone seem to have been sensible of his merits. The weight of poverty too was hard to bear. In 1813 Ingres had married; his marriage had been arranged for him with a young woman who came in a business-like way from Montauban, on the strength of the representations of her friends in Rome to whom the painter was well known. Mme. Ingres speedily acquired a faith in her husband which enabled her to combat with heroic courage and patience the difficulties which beset their common existence, and which were increased by their removal to Florence. There Bartolini, an old friend, had hoped that Ingres might have materially bettered his position, and that he might have aroused the Florentine school—a weak offshoot from that of David—to a sense of its own shortcomings. These expectations were disappointed. The good offices of Bartolini, and of one or two persons who felt a friendly interest in the painter, could only alleviate the miseries of this stay in a town where Ingres was all but wholly deprived of the means of at least gaining daily bread by the making of those small portraits for the execution of which, in Rome, his pencil had been constantly in request. Before his departure he had, however, been commissioned to paint for M. de Pastoret the Entry of Charles V. into Paris, and M. de Pastoret now obtained an order for Ingres from the Administration of Fine Arts; he was directed to treat the Vœu de Louis XIII. for the cathedral of Montauban. This work, which was exhibited at the Salon of 1824, met with universal approbation: even those sworn to observe the unadulterated precepts of David found only admiration for the Vœu de Louis XIII. On his return Ingres was received at Montauban with enthusiastic homage, and found himself celebrated throughout France. In the following year (1825) he was elected to the Institute, and his fame was further extended in 1826 by the publication of Sudre's lithograph of the Grande Odalisque, which, having been scorned by artists and critics alike in 1819, now became widely popular. A second commission from the Government called forth the Apotheosis of Homer, which, replaced by a copy in the decoration of the ceiling for which it was designed, now hangs in the galleries of the second story of the Louvre. From this date up till 1834 the studio of Ingres was thronged, as once had been thronged the studio of David, and he was a recognized *chef d'école*. Whilst he taught with despotic authority, and admirable wisdom, he steadily worked; and when in 1834 he produced his great canvas of the Martyrdom of Saint Symphorien (cathedral of Autun; lithographed by Trichot-Garneri), it was with angry disgust and resentment that he found his work received with the same doubt and indifference, if not the same hostility, as had met his earlier ventures. The suffrages of his pupils, and of one or two men—like Decamps—of undoubted ability, could not soften the sense of injury. Ingres resolved to work no longer for the public, and gladly availed himself of the opportunity to return to Rome, as director of the École de France, in the room of Horace Vernet. There he executed La Vierge à l'Hostie (Imperial collections, St. Petersburg), Stratonice (Duc d'Aumale), Portrait of Cherubini (Louvre), and the Petite Odalisque for M. Marcotte, the faithful admirer for whom, in 1814, Ingres had painted the Chapelle Sistine. The Stratonice, executed for the duke of Orleans, had been exhibited at the Palais Royal for several days after its arrival in France, and the beauty of the composition produced so favorable an impression that, on his return to Paris in 1841, Ingres found himself received with all the deference that he felt to be his due. A portrait of the purchaser of Stratonice was one of the first works executed after this return: and Ingres shortly afterwards began the decorations of the great hall in the Château de Dampierre, which, unfortunately for the reputation of the painter, were begun with an ardor which gradually slackened, until in 1849 Ingres, having been further discouraged by the irreparable loss of his faithful and courageous wife, abandoned all hope of their completion, and the contract with the Duc de Luynes was finally cancelled. A minor work, Jupiter and Antiope, marks the year 1851, but Ingres's next considerable undertaking (1853) was the Apotheosis of Napoleon I., painted for the ceiling of a hall in the Hôtel de Ville; Jeanne d'Arc (Louvre) appeared in 1854; and in 1855 Ingres consented to rescind the resolution more or less strictly kept since 1834, in favor of the International Exhibition, where a room was wholly reserved for his works. In consequence of the effect which they produced, Prince Napoleon, president of the jury, proposed an exceptional recompense for their author, and obtained from the emperor Ingres's nomination as grand officer of the Legion of Honor. With renewed confidence Ingres now took up and completed one of his most charming productions—La Source (Louvre), a figure of which he had painted the torso in 1823, and which seen with other works in London (1862) there renewed the general sentiment of admiration, and procured him, from the imperial government, the dignity of senator. After the completion of La Source, the principal works produced by Ingres were with one or two exceptions (Molière and Louis XIV., presented to the Théâtre Français, 1858; Le Bain Turc, 1859), of a religious character; La Vierge de l'Adoption, 1858 (painted for Mdlle. Roland-Gosselin), was followed by La Vierge Couronnée (painted for Mme. la Baronne de Larinthie) and La Vierge aux Enfans (Collection Blanc); in 1859 these were followed by repetitions of La Vierge à l'Hostie; and in 1862 Ingres completed Christ and the Doctors (Musée Montauban), a work commissioned many years before by Queen Marie Amélie for the chapel of Bizy. On the 14th January, 1867, Ingres died, in his eighty-eighth year, having preserved his faculties in wonderful perfection to the last. For a moment only—at the time of the execution of the Bain Turc, which Prince Napoleon was fain to exchange for an early portrait of the master by himself—Ingres's powers had seemed to fail, but he recovered, and showed in his last years the vigor which marked his early maturity. It is, however, to be noted that the Saint Symphorien exhibited in 1834 closes the list of the works on which his reputation will chiefly rest; for La Source, which at first sight seems to be an exception, was painted, all but the head and the extremities, in 1821; and from those who knew the work well in its incomplete state we learn that the after-painting, necessary to fuse new and old, lacked the vigor, the precision, and the something like touch which distinguished the original execution of the torso. Touch was not, indeed, at any time a means of expression on which Ingres seriously calculated: his constant employment of local tint, in mass but faintly modelled in light by half tones, forbade recourse to the shifting effects of color and light on which the Romantic school depended in indicating those fleeting aspects of things which they rejoiced to put on canvas;—their methods would have disturbed the calculations of an art wholly based on form and line. Except in his Sistine Chapel, and one or two slighter pieces, Ingres kept himself free from any preoccupation as to depth and force of color and tone; driven, probably by the excesses of the Romantic movement into an attitude of stricter protest, "ce que l'on sait," he would repeat, "il faut le savoir l'épée à la main." Ingres left himself, therefore, in dealing with crowded compositions, such as the Apotheosis of Homer and the Martyrdom of Saint Symphorien, without the means of producing the necessary unity of effect which had actually been employed in due measure—as the Stanze of the Vatican bear witness—by the very master whom he most deeply reverenced. Thus it came to pass that in subjects of one or two figures Ingres showed to the greatest advantage: in Œdipus, in the Girl after Bathing, the Odalisque, and La Source—subjects only animated by the consciousness of perfect physical well-being—we find Ingres at his best. One hesitates to put Roger and Angelique upon this list, for though the female figure shows the finest qualities of Ingres's work,—deep study of Nature in her purest forms, perfect sincerity of intention and power of mastering an ideal conception,—yet side by side with these the effigy of Roger on his hippogriff bears witness that from the passionless point of view, which, as before said, was Ingres's birthright, the weird creatures of the fancy cannot be seen. A graphic account of "Ingres, sa vie et ses travaux," and a complete catalogue of his works, were published by M. Delaborde in 1870, and dedicated to Mme. Ingres *née* Ramel, Ingres's devoted second wife, whom he married in 1852. Allusions to the painter's early days will be found in Delécluze's *Louis David*; and amongst many less important notices may be cited that by Théophile Silvestre in his series of living artists. Most of Ingres's important works are engraved in the collection brought out by Magimel.

(E. F. S. P.)

INGULPHUS [Ingulf], abbot of Crowland, for a long period believed to be the author of the *Historia Monasterii Croylandensis*, was born of English parents. The account of him given at the conclusion of the *Historia* has been shown to be incorrect in several particulars, but according to the authority of Ordericus Vitalis, who visited Crowland three years after the death of Ingulf, he became secretary to William, duke of Normandy, and after taking part in a pilgrimage to Jerusalem, lived as a monk in Normandy, where he rose to the rank of prior. After the accession of William to the throne of England, he in 1085 received the abbatial stall of Crowland, Lincolnshire, where he remained till his death, December 16, 1109. Through his influence with the conqueror he secured for the abbey many valuable privileges and immunities, besides the reconstruction and enlargement of the building itself, which had been greatly damaged by the Danes in 870. The only manuscript of the *History* of Ingulf now known to exist is the Arundel manuscript, No. 178, in the British Museum, which breaks off at the same point as that published by Sir Henry Savile in the *Scriptores Rerum Anglicarum post Bedam*, London, 1596. Other four manuscripts are known to have been at one time in existence; and a more complete copy with a continuation by Peter de Blois was printed by Fulman in vol. i. of the *Rerum Anglicarum Scriptores veteres*, Oxford, 1684. The authenticity of this work was, however, disputed by Sir Francis Palgrave in the *Quarterly Review* for September, 1826, and the errors which it contains show beyond doubt that it must have been written by a later author, and entirely destroy its value as an historical authority. The work, edited by H. S. Riley, forms vol. xxix. of Bohn's Antiquarian Library. Two elaborate papers by Mr. Riley in opposition to its authenticity are contained in the *Archæological Journal*, March and June, 1862. A full account of it is also given in Hardy's *Rerum Britannicarum Medii Ævi Scriptores*, vol. ii. 1865.

INHERITANCE. In English law, inheritance, heir, and other kindred words have a meaning very different from that of the Latin *hæres*, from which they are derived. In Roman law the heir or heirs represented the entire legal personality of the deceased—his *universum jus*. In English law the heir is simply the person on whom the real property of the deceased devolves by operation of law if he dies intestate. He has nothing to do as heir with the personal property; he is not appointed by will; and except in the case of coparceners he is a single individual. The Roman *hæres* takes the whole estate; his appointment may or may not be by testament; and more persons than one may be associated together as heirs.

The devolution of an inheritance in England is now regulated by the rules of descent, as altered by the Inheritance Act (3 & 4 Will. IV. c. 106), amended by 22 & 23 Vict. c. 35. 1. The first rule is that inheritance shall descend to the issue of the last "purchaser." A purchaser in law means one who acquires an estate otherwise than by descent, *e. g.* by will, by gratuitous gift, or by purchase in the ordinary meaning of the word. This rule is one of the changes introduced by the Inheritance Act, which further provides that "the person last entitled to the land shall be considered the purchaser thereof unless it be proved that he inherited the same." Under the earlier law descent was traced from the last person who had "seisin" or feudal possession, and it was occasionally a troublesome question whether the heir or person entitled had ever, in fact, acquired such possession. Now the only inquiry is into title, and each person entitled is presumed to be in by purchase unless he is proved to be in by descent, so that the stock of descent is the last person entitled who cannot be shown to have inherited. 2. The male is admitted before the female. 3. Among males of equal degree in consanguinity to the purchaser, the eldest excludes the younger; but females of the same degree take together as "coparceners." 4. Lineal descendants take the place of their ancestors. Thus an eldest son dying and leaving issue would be represented by such issue, who would exclude their father's brothers and sisters. 5. If there are no lineal descendants of the purchaser, the next to inherit is his nearest lineal ancestor. This is a new rule introduced by the Inheritance Act. Under the former law inheritance never went to an ancestor,—collaterals, however remote, of the person last seized being preferred even to his father. Various explanations have been given of this seemingly anomalous rule,—Bracton and Blackstone being content to say that it rests on the law of nature, by which heavy bodies gravitate downwards. Another explanation is that estates were granted to be descendible in the same way as an ancient inheritance, which having passed from father to son *ex necessitate* went to collaterals on failure of issue of the person last seized. 6. The sixth rule is thus expressed by Mr. Joshua Williams in his excellent treatise on *The Law of Real Property:* "The father and all the male paternal ancestors of the purchaser and their descendants shall be admitted before any of the female paternal ancestors or their heirs; all the female paternal ancestors and their heirs before the mother or any of the maternal ancestors or her or their descendants; and the mother and all the male maternal ancestors and her and their descendants before any of the female maternal ancestors or their heirs." 7. A kinsman of the whole blood shall come before the same degree of the half blood. The admission of kinsmen of the half blood into the chain of descent is one of the alterations made by the Inheritance Act. Formerly a relative, however nearly connected in blood with the purchaser through one only and not both parents, could never inherit—a half-brother for example; while relatives of the whole blood, however distant, might inherit to the exclusion of nearer relatives of the half blood. 8. In the admission of female paternal ancestors, the mother of the more remote male paternal ancestor and her heirs shall be preferred to the mother of the less remote male paternal and her heirs; and, in the case of female maternal ancestors, the mother of the more remote male maternal ancestor shall be preferred to the mother of a less remote male maternal ancestor. This rule, following the opinion of Blackstone, settles a point which has been much disputed by text-writers, although its importance was little more than theoretical. 9. When there shall be a total failure of heirs of the purchaser, or when any lands shall be descendible as if an ancestor had been the purchaser thereof, and there shall be a total failure of the heirs of such ancestor, then and in every such case the descent shall be traced from the person last entitled to the land as if he had been the purchaser thereof. This rule is enacted by 22 & 23 Vict. c. 35. It would apply to such a case as the following:—Purchaser dies intestate, leaving a son and no other relations, and the son in turn dies intestate; the son's relations through his mother are now admitted by this rule. If the purchaser is illegitimate, his only relations must necessarily be his own issue. Failing heirs of all kinds, the lands of an intestate purchaser, not alienated by him, would revert by "escheat" to the next immediate lord of the fee, who would generally be the crown. If an intermediate lordship could be proved to exist between the crown and the tenant in fee simple, such intermediate lord would have the escheat. But escheat in any case is a matter of rare occurrence.

The descent of an estate in tail would be ascertained by such of the foregoing rules as are not inapplicable to it by the necessity of the case. By the form of the entail the estate descends to the "issue" of the person to whom the estate was given in tail,—in other words, the last purchaser. The preceding rules, after the fourth, being intended for the ascertainment of heirs other than those by lineal descent, would therefore not apply; and a special limitation in the entail, such as to heirs male or female only, would render unnecessary some of the others. When the entail has been barred, the estate of course descends according to these rules. In copyhold estates descent, like other incidents thereof, is regulated by the custom of each particular manor; *e. g.*, the youngest son may exclude the elder sons. How far the Inheritance Act applies to such estates has been seriously disputed. It has been held in one case (Muggleton *v.* Barnett) that the Inheritance Act, which orders descent to be traced from the last purchaser, does not override a manorial custom to trace descent from the person last seized, but this position has been controverted on the ground that the Act itself includes the case of customary holdings.

Husband and wife do not stand in the rank of heir to each other. Their interests in each other's real property are secured by courtesy and dower. See HUSBAND AND WIFE.

The personal property of a person dying intestate devolves according to an entirely different set of rules, which will be found under the head of INTESTACY.

In the law of Scotland the rules of descent differ from the above in several particulars. Descent is traced, as in England before the Inheritance Act, to the person last seized. The first to succeed are the lineal descendants of the deceased, and the rules of primogeniture, preference of males to females, equal succession of females (heirs-portioners), and representation of ancestors, are generally the same as in English law. Next to the lineal descendants, and failing them, come the brothers and sisters, and their issue as collaterals. Failing collaterals, the inheritance ascends to the father and his relations, to the entire exclusion of the mother and her relations. Even when the estate has descended from mother to son, it can never again revert to the maternal line. As to succession of brothers, a distinction must be taken between an estate of heritage and an estate of conquest. Conquest is where the deceased has acquired the land otherwise than as heir, and corresponds to the English term purchase in the technical sense explained above. Heritage is land acquired by deceased as heir. The distinction is important only in the case when the heir of the deceased is to be sought among his brothers; when the descent is lineal, conquest and heritage go to the same person. And when the brothers are younger than the deceased, both conquest and heritage go to the brother (or his issue) next in order of age. But when the deceased leaves an elder and a younger brother (or their issues), the elder brother takes the conquest, the younger takes the heritage. Again, when there are several elder brothers, the one next in age to the deceased takes the conquest before the more remote; and when there are several younger brothers, the one next to the deceased takes the heritage before the more remote. When heritage of the deceased goes to an elder brother (as might happen in certain eventualities), the younger of the elder brothers is preferred. The position of the father, after the brothers and sisters of the deceased, will be noticed as an important point of difference from the English axioms; so also is the total exclusion of the mother and the maternal line. After brothers and sisters and their issue have been exhausted, the heir is sought among the relations of the father; but even when these are exhausted, the estate, although it should have descended *ex parte materna*, can never revert to the maternal line. As between brothers and sisters the half-blood only succeeds after the full blood. Half-blood is either consanguinean, as between children by the same father, or uterine, as between children having the same mother. The half-blood uterine is excluded altogether. Half-blood consanguinean succeeds thus: if the issue is by a former marriage, the youngest brother (being nearest to the deceased of the consanguinean) succeeds first; if by a later marriage than that from which the deceased has sprung, the eldest succeeds first.

In the United States the English law of inheritance has been more completely repudiated than any other portion of our system. Each State has established rules of descent for itself, and the observation of Chief Justice Reeve that the nation "has no general law of descents, which probably has not fallen to the lot of any other country," is to some extent justified by the great differences in detail between the rules obtaining in the different States. The following are the rules of most general application, as stated in Kent's *Commentaries on American Law*, twelfth edition, edited by O. W. Holmes, jun. 1. Real estate shall descend to the lawful descendants of the owner, in the direct line of lineal descent; and if there be but one person, then to him or her alone; and if more than one person, and all of equal degrees of consanguinity to the ancestor, then to the several persons or tenants in common in equal parts, however remote from the intestate the common degrees of consanguinity may be. 2. When the lawful issue are of unequal degrees of consanguinity to the intestate, the inheritance shall descend to the children and grandchildren, if any be living, and to the issue of such as shall be dead, as tenants in common; but such grandchildren and their descendants inherit only such shares as their parents respectively would have taken if living. These two rules are stated to prevail in all the United States, with some important variations, however, in the case of the first rule. 3. In the absence of descendants the inheritance goes to the parents, either first to the father and next to the mother, or jointly under certain conditions. This canon is described as prevailing "to a considerable extent." 4. If the intestate dies without issue or parents the estate goes to his brothers and sisters and their representatives. If the relatives are of equal degrees of consanguinity they take in equal parts; but if, of the same degree, some be dead, leaving issue, and others living, the descendants of those who are dead take only their parents' share. Collaterals under this rule would be preferred to ascendants—after parents. "It is perhaps universally the rule that brothers and sisters are preferred to grandparents, though the latter stand in an equal degree of kindred" (Kent, vol. iv. p. 401). In some States there is no essential distinction left between the whole and the half-blood, in others the half-blood is postponed, but nowhere is it totally excluded. 5. In default of the foregoing, the inheritance generally goes to grandparents, but in some States (New York, New Jersey, and North Carolina) grandparents are excluded, and in others postponed. 6. Next come uncles and aunts and their decendants, taking *per capita* if of equal degree, and *per stirpes* if not. 7. If the inheritance came to the deceased on the part of his father, the father's brothers and sisters would exclude the mother's brothers and sisters, and the mother's brothers and sisters would have a similar preference in respect of property coming to the deceased *ex parte materna*. A similar distinction is observed in some States in applying the fourth rule. 8. On failure of heirs under the preceding rules, recourse is had to the "next-of-kin" as ascertained by the English statute of distributions. In many of the States the harshness of the English rule that natural children have no inheritable blood is greatly mitigated. In Louisiana, if duly acknowledged, they may inherit from both father and mother in the absence of lawful issue.

A full summary of the rules of descent prescribed by the statute law of the various States of the Union will be found in a note appended to the first chapter of Washburn's *American Law of Real Property*, vol. iii., Boston, 1868.

INJUNCTION, in English law, is a judicial process whereby a party is required to refrain from doing a particular thing according to the exigency of the writ (Daniel's *Chancery Practice*). Formerly it was a remedy peculiar to the Court of Chancery, and was one of the instruments by which the jurisdiction of that court was established in cases over which the courts of common law were entitled to exercise control. The Court of Chancery did not presume to interfere with the action of the courts, but, by directing an injunction to the person whom it wished to restrain from following a particular remedy at common law, it effected the same purpose indirectly. Under the present constitution of the judicature, the peculiar features of the injunction have been considerably altered. It is now equally available in all the divisions of the high court of justice, and it can no longer be used to prevent an action in any of them from proceeding in the ordinary course.

From the definition given above it is apparent that an injunction is properly a restraining order, although there are instances in which, under the form of a prohibition, a positive order to do something is virtually expressed. Thus in a case of nuisance an injunction was obtained to restrain the defendant from preventing water from flowing in such regular quantities as it had ordinarily done before the day on which the nuisance commenced. But generally, if the relief prayed for is to compel something to be done, it cannot be obtained by injunction, although it may be expressed in the form of a prohibition—as in the case in which it was sought to prevent a person from discontinuing to keep a house as an inn, which is the same thing as ordering him to keep an inn. The injunction was used to stay proceedings in other courts "wherever a party by fraud, accident, mistake, or otherwise had obtained an advantage in proceeding in a court of ordinary jurisdiction, which must necessarily make that court an instrument of injustice." As the injunction operates personally on the defendant, it may be used to prevent applications to foreign judicatures; but it is not used to prevent applications to parliament, or to the legislature of any foreign country, unless such applications be in breach of some agreement, and relate to matters of private interest. In so far as an injunction is used to prohibit acts, it may be founded either on an alleged contract or on a right independent of contract. The jurisdiction of the court to prevent breaches of contract has been described as supplemental to its power of compelling specific performance; *i. e.*, if the court has power to compel a person to perform a contract, it will interfere to prevent him from doing anything in violation of it. In the case of contracts to abstain from doing, injunction is in fact a means of compelling specific performance. But even when it is not within the power of the court to compel specific performance, it may interfere by injunction; thus, *e. g.*, in the case of an agreement of a singer to perform at the plaintiff's theatre and at no other, the court, although it could not compel her to sing, could by injunction prevent her from singing elsewhere in breach of her agreement. In other matters, an injunction may as a general rule be obtained to prevent acts which are violations of legal rights, except when the same may be adequately remedied by an action for damages at law. Thus the court will interfere by injunction to prevent waste, or the destruction by a limited owner, such as a tenant for life, of things forming part of the inheritance. Injunctions may also be obtained to prevent the continuance of nuisances, public or private, the infringement of patents, copyrights, and trade marks. Trespass might also be prevented by injunction, in certain cases, alluded to below. Under the Common Law Procedure Act of 1854, and by other statutes in special cases, a limited power of injunction was conferred on the courts of common law. But the Judicature Act, by which all the superior courts of common law and chancery are consolidated, enacts that an injunction may be granted by an interlocutory order of the court in all cases in which it shall appear to be just or convenient; . . . and, if an injunction is asked either before or at or after the hearing of any cause or matter, to prevent any threatened or apprehended waste or trespass, such injunction may be granted whether the person against whom it is sought is or is not in possession under any claim of title or otherwise, or if not in possession does or does not claim to do the act sought to be restrained under color of any title, and whether the estates claimed are legal or equitable.

An injunction obtained on interlocutory application during the progress of an action is superseded by the trial. It may be continued either provisionally or permanently. In the latter case the injunction is said to be perpetual. The distinction between "special" and "common" injunctions—the latter being obtained as of course—is now abolished in English law. The practice as to injunctions obtains in the United States of America. "In the courts of the United States, as injunctions are grantable only on notice to the adverse party, all interlocutory injunctions are regarded as within the class of special injunction; and this is believed to be also the practice of the State courts generally" (Abbott's *Law Dictionary*). For the analogous Scotch practice see INTERDICT.

INK (French, *encre;* German, *Tinte*), in its widest signification, is the medium employed for producing graphic tracings, inscriptions, or impressions on paper or similar materials. The term includes two distinct conditions of pigment or coloring matter:—the one fluid, and prepared for use with a pen or brush, as writing ink; the other a glutinous adhesive mass, printing ink, used for transferring to paper impressions from types, engraved plates, and other like surfaces. The latter class may be more properly dealt with under LITHOGRAPHY and PRINTING (*q. v.*).

Writing inks are fluid substances which contain coloring matter either in solution or in suspension, and very commonly partly in both conditions. They may be prepared in all shades of color, and contain in their composition almost every pigment which can be dissolved or suspended in a suitable medium; but by far the most important of all varieties is black ink, after which red and blue are the colors most commonly employed. Other colors are only occasionally employed; but apart from color there are special qualities which recommend certain inks for limited applications, such as marking inks, ineradicable ink, sympathetic ink, etc.

Black Ink.—Among the qualities which should characterize a good black ink for ordinary purposes, the following are important. It should continue limpid, and flow freely and uniformly from the pen; it should not throw down a thick sludgy deposit on exposure to the air; nor should a coating of mould form on its surface. It should yield distinctly legible characters immediately on writing, which ought to become a deep blue-black, not fading or decaying with age; and the fluid ought to penetrate into the paper without spreading, so that the characters will neither wash out nor be readily removed by erasure. Further, it is desirable that ink should be non-poisonous, that it should as little as possible corrode steel pens, that characters traced in it should dry readily on the application of blotting paper without smearing, and that the writing should not present a glossy varnished appearance. To obtain these characteristics is the chief object of the ink manufacturer; and upon the whole they have hitherto been found best combined in ink prepared from galls, or other sources of tannin, and a salt of iron, with the addition of some coloring matter. Such a compound indeed forms the staple black ink of commerce, which is essentially a ferroso-ferric gallate in extremely fine division held in suspension in water.

The essential ingredients of this ordinary black ink are—first, tannin-yielding bodies, for which Aleppo or Chinese galls are the only eligible materials; second, a salt of iron, the ferrous sulphate (green vitriol) being alone employed; and third, a gummy or mucilaginous agent to keep in suspension the insoluble tinctorial matter of the ink. For ink-making the tannin, from whatever source obtained, has first to be transformed into gallic acid; and, as has been shown by Viedt, in the case of Aleppo galls that change takes place by fermentation when the solution of the galls is exposed to the air, the tannin splitting up into gallic acid and sugar (see GALLIC ACID, vol. x. p. 37). Chinese galls, which formerly were considered unsuitable for the manufacture of ink, do not contain the ferment necessary for inducing this change; and therefore to induce the process yeast must be added to their solution. To prepare a solution of Aleppo galls for ink-making, the galls are coarsely powdered, and intimately mixed with chopped straw. This mixture is thrown into a narrow deep oak vat, provided with a perforated false bottom, and having a tap at the bottom for drawing off liquid. Over the mixture is poured lukewarm water, which, percolating down, extracts and carries with it the tannin of the galls. The solution is drawn off and repeatedly run through the mixture to extract the whole of the tannin, the quantity of water used being in such proportion to the galls as will produce as nearly as possible a solution having 5 per cent. of tannin. The object of using straw in the extraction process is to maintain the porosity of the mixture, as powdered galls treated alone become so slimy with mucilaginous extract that liquid fails to percolate the mass. For each litre of the 5 per cent. solution about 45 grammes of the iron salt are used, or about 100 parts of tannin for 90 parts of crystallized green vitriol. These ingredients when first mixed form a clear solution, but on their exposure to the air oxidation occurs, and an insoluble blue-black ferroso-ferric gallate in extremely fine divisions, suspended in a colored solution of ferrous gallate, is formed. To keep the insoluble portion suspended, a mucilaginous agent is employed, and that most available is gum senegal. An ink so prepared develops its intensity of color only after some exposure; and after it has partly sunk into the paper it becomes oxidized there, and so mordanted into the fibre. But, as the first faintness of the characters is a disadvantage, it is a common practice to add some adventitious coloring matter to give immediate distinctness, and for that purpose either extract of logwood or a solution of indigo is used. When logwood extract is employed, a smaller proportion of extract of galls is required, from the fact that logwood itself contains a large percentage of tannin. Black ink in which the provisional coloring matter is indigo was introduced about the year 1856, under the name alizarin ink, although the substance alizarin has nothing whatever to do with the preparation. The indigo for this ink is dissolved in strong sulphuric acid, and the ferrous sulphate, instead of being used direct, is prepared by placing in this indigo solution a proper quantity of scrap iron. In order to free the solution from excess of uncombined acid, chalk or powdered limestone is added, whereby the free acid is fixed and a deposit of sulphate of lime formed. A solution so prepared, mixed with a tannin solution, yields a very limpid sea-green writing fluid, and as all the constituents remain in solution, no gum or other suspending medium is necessary. In consequence the ink flows freely, is easily dried, and is free from the glossy appearance which arises through the use of gum. C. H. Viedt of Brunswick, who has written very exhaustively on all kinds of ink, gives the following as the standard ingredients of these three varieties of ink:—

	Galls Ink.	Galls-logwood Ink.	Galls-indigo Ink.
Tannin extract 5 per ct.	1 litre	⅔ litre	1 litre
Ferrous sulphate	45 grammes	45 grammes	...
Gum senegal	20–30 "	20–30 "	...
Logwood solution, 3 per cent	...	⅓ litre	...
Metallic iron	...	...	9 grammes
Indigo	...	...	6¼ "
Concentrated sulphuric acid	...	...	25 "
Chalk	...	...	1 "

On long exposure to air, as in inkstands, or otherwise, all these varieties of ink gradually become thick and ropy, depositing a slimy sediment. This change on exposure is inevitable, resulting as it does from the gradual and at the same time essential oxidation of the ferrous compound, and it can only be retarded by permitting access of air to as small surfaces as possible. The inks also have a tendency to become mouldy, an evil which may be obviated by the use of a minute proportion of carbolic acid; or, should that body be objectionable on account of its smell, salicylic acid may be used.

Under the name of chrome ink a black ink was discovered and prepared by the chemist Runge, which held out the promise of cheapness combined with many excellent qualities. It is prepared by dissolving 15 parts of extract of logwood in 900 parts of water, to which 4 parts of crystallized sodic carbonate are added. A further solution of 1 part of chromate (not bichromate) of potassium in 100 parts of water is prepared, and is added very gradually to the other solution with constant agitation. Thereby is obtained an ink which possesses an intense blue-black color, which flows freely and dries readily, which being neutral in reaction, does not corrode steel pens, and which so adheres to and sinks into paper that manuscripts written with it may be freely washed with a sponge without danger of smearing or spreading. It forms a good copying ink, and in short it possesses all the qualities essential to the best ink; but unfortunately on exposure to air it very readily undergoes decomposition, the coloring matter separating in broad flakes, which swim in a clear menstruum. It is affirmed by Viedt that this drawback may be overcome by the use of soda, a method first suggested by Böttger.

Logwood forms the principal ingredient in various other black inks which are now much used, especially as copying ink. A very strong decoction of logwood or a strong solution of the extract with ammonia-alum yields a violet ink which darkens slowly on exposure. Such an ink is costly, however, on account of the concentrated condition in which the logwood must be used. If, however, a metallic salt is introduced, a serviceable ink is obtained with the expenditure of much less logwood. Either sulphate of copper or sulphate of iron may be used, but the former, which produces a pleasing blue-black color, is to be preferred. The following is the formula most highly recommended for this ink. A clear solution of 20 kilos of extract of logwood in 200 litres of water is obtained, to which is added, with agitation, 10 kilos of ammonia-alum dissolved in 20 litres of boiling water. The solution is acidified with 0·2 kilo of sulphuric acid, which has the effect of preventing any deposit, and finally there is added a solution of 1·5 kilos of sulphate of copper dissolved in 20 litres of water. This compound is exposed to the air for a few days to allow the color to develop by oxidation, after which it is stored in well-corked bottles. The acid condition of this ink has a corrosive influence on steel pens; but in all other respects it is a most valuable writing fluid.

A black ink under the name of nigrosin is prepared from a soluble aniline color, which, although not producing a black so intense as common ink, is possessed of various advantages. Being perfectly neutral, it does not attack pens; it can easily be kept of a proper consistency by making up with water; and its color is not injuriously affected by the action of acids.

Copying Ink.—Ink which yields by means of pressure an impression, on a sheet of damped tissue paper, of characters written in it is called copying ink. Any ink soluble in water, or which retains a certain degree of solubility, may be used as copying ink. Runge's chrome ink, being a soluble compound, is, therefore, so available; and the other logwood inks as well as the ordinary ferrous gallate inks contain also soluble constituents, and indeed are essentially soluble till they are oxidized in and on the paper after exposure to the air. To render these available as copying inks it is only necessary to add to them a substance which will retard the oxidizing effect of the air for some time. For this purpose the bodies most serviceable are gum arabic or senegal, with glycerin, dextrin, or sugar, which last, however, has the disadvantage of rendering the ink sticky. These substances act by forming a kind of glaze or varnish over the surface of the ink which excludes the air. At the same time when the damp sheet of tissue paper is applied to the writing they dissolve and allow a portion of the yet soluble ink to be absorbed by the moistened tissue. As copying ink has to yield two or more impressions, it is necessary that it should be made stronger, *i. e.*, that it should contain more pigment or body than common ink. It, therefore, is prepared with from 30 to 40 per cent. less of water than non-copying kinds; but otherwise, except in the presence of the ingredients above alluded to, the inks are quite the same.

Red Ink.—The pigment most commonly employed as the basis of red ink is Brazil-wood, a dye-stuff which yields a good durable ink. Such an ink is prepared by adding to a strong decoction of the wood a proportion of stannous chloride (tin spirits), and thickening the resulting fluid with gum arabic. In some instances alum and cream of tartar are used instead of the stannous chloride. Cochineal is also employed as the tinctorial basis of red ink; but, while the resulting fluid is much more brilliant than that obtained from Brazil-wood, it is not quite so permanent. A very brilliant red ink may be prepared by dissolving carmine in a solution of caustic ammonia, but it is necessary to keep this preparation in closely stoppered bottles. A useful red ink may also be made by dissolving the rosein of Brooke, Simpson, and Spiller in water, in the proportion of 1 to from 150 to 200 parts.

Blue Ink.—For the production of blue ink the pigment principally used is Prussian blue. To render this color soluble in water, it is first digested for two or three days with either strong hydrochloric acid, sulphuric acid, or nitric acid, the digested mass is next very largely diluted with water, and after settling the supernatant liquid is siphoned away from the sediment. This sediment is repeatedly washed, till all traces of iron and free acid disappear from the water used, after which it is dried and mixed with oxalic acid in the proportion of 8 parts of Prussian blue to 1 of the acid, and in this condition the material is ready for dissolving in water to the degree of color intensity necessary. An aniline blue ink may be prepared by dissolving 1 part of bleu de Paris in from 200 to 250 parts of water.

China ink or *Indian ink* is the form in which ink was earliest prepared, and in which it is still made and used in China and Japan for writing with small brushes instead of pens. It is extensively used by architects, engineers, and artists generally, and for various special uses. China ink is prepared in the form of sticks and cakes, which are rubbed down in water for use. It consists essentially of lamp-black in very fine condition, baked up with a glutinous substance; and the finer Oriental kinds are delicately perfumed. The following description of the manufacture as conducted in Japan is from a native source:—"The body of the ink is soot obtained from pine wood or rosin, and lamp-black from sesamum oil for the finest sort. This is mixed with liquid glue made of ox skin. This operation is effected in a large round copper bowl, formed of two spherical calottes, placed 1 inch apart, so that the space between can be filled up with hot water to prevent the glue from hardening during the time it is being mixed by hand with the lamp-black. The cakes are formed in wooden moulds, and dried between paper and ashes. Camphor, or a peculiar mixture of scents which comes from China, and a small quantity of carthamine (the red coloring substance of safflower), are added to the best kinds for improving the color as well as for scenting the ink. There is a great difference both in price and in quality of the various kinds of ink, the finest article being rather costly." It is said that the size used in Chinese kinds is of vegetable origin.

Marking Ink.—The ink so called, used principally for marking linen, is composed of a salt of silver, usually the nitrate, dissolved in water and ammonia, with a little provisional coloring matter and gum for thickening. The color resulting from the silver salt is developed by heat and light; and the stain it makes, although exceedingly obstinate, gradually becomes a faint brownish-yellow. The following yields a good marking ink. Equal parts of nitrate of silver and dry tartaric acid are triturated in a mortar, and treated with water, when a reaction takes place, resulting in the formation of tartrate of silver and the liberation of nitric acid. The acid is neutralized, and at the same time the silver tartrate is dissolved by the addition of ammonia, and this solution with coloring matter and gum forms the ink, which may be used with an ordinary steel pen.

Gold and *silver inks* are writing fluids in which gold and silver, or imitations of these metals, are suspended in a state of fine division. In place of gold, Dutch leaf or mosaic gold is frequently substituted, and bronze powders are also used for preparing a similar kind of ink. The metallic foil is first carefully triturated into a fine paste with honey, after which it is boiled in water containing a little alkali, and then repeatedly washed in hot water and dried at a gentle heat. A solution is prepared consisting of 1 part of pure gum arabic and one part of soluble potash glass in 4 parts of distilled water, into which the requisite quantity of the metallic powder prepared as above is introduced. Owing to the superior covering nature of pure gold, less of the metal is required than is necessary in the case of silver and other foils; but the proportion varies according to the color and condition of the surface upon which the ink is to be used. In general 1 part of foil to 3 or 4 parts of solution is sufficient. The metallic lustre of writing done with this solution may be greatly heightened by gently polishing with a burnishing point.

Indelible or *incorrodible ink* is the name given to various combinations of lamp-black or other carbonaceous material with resinous substances used for writing which is exposed to the weather or to the action of strong acids or alkaline solutions. An ink having great resisting powers may be conveniently prepared by rubbing down Indian ink in common ink till the mixture flows easily from the pen. Other combinations have more the character of colored varnishes.

Sympathetic inks are preparations used for forming characters which only become visible on the application of heat or of some chemical reagent. Many chemicals which form in themselves colorless solutions, but which develop color under the influence of reagents, may be used as sympathetic ink, but they are all of little practical utility. Characters written in a weak solution of galls develop a dark color on being treated with a solution of copperas; or, *vice versa*, the writing may be done in copperas and developed by the galls solution. Writing done in various preparations develops color on heating which fades as the paper cools. Among such substances are solutions of the acetate and the chloride of cobalt and of the chloride of nickel. Very dilute solutions of the mineral acids and of common salt and a solution of equal parts of sulphate of copper and sal-ammoniac act similarly. Characters traced in a weak solution of nitrate of silver darken on exposure to light, and terchloride of gold solution develops a purple color on exposure. (J. PA.)

INLAYING is a method of ornamentation, by incrusting or otherwise inserting in one material a substance or substances differing therefrom in color or nature. The art is practised in the fabrication of furniture and artistic objects in all varieties of wood, metal, shell, ivory, and colored and hard stone and in compound substances; and the possible combinations, styles, and varieties of effect are exceedingly numerous. There are several special classes of inlaying, long established and well recognized, which may be here enumerated and defined, details regarding most of which will be found under their separate headings. In the ornamental treatment of metal surfaces, *Niello* decoration, applied to silver and gold, is an ancient and much practised species of inlaying. It consists in filling up engraved designs with a composition of silver, copper, lead, and sulphur incorporated by heat. The composition is black and the finished work has the appearance of a drawing in black on a metallic plate. An art, analogous in effect, called *Bidri*, from Bider in the Deccan, is practised in India. In bidri work the ground is an alloy of zinc, with small proportions of copper and lead, in which shallow patterns and devices are traced and filled up with thin plates of silver. When the surface has been evened and smoothed the bidri ground is stained a permanent black by means of a paste, the chief ingredients of which are sal-ammoniac and nitre, leaving a pleasing contrast of bright metallic silver in a dead-black ground. The inlaying of gold wire in iron or steel is known as DAMASKEENING (*q. v.*, vol. vi. p. 698). It has been very largely practised in Persia and India for the ornamentation of arms and armor, being known in the latter country as Kuft work or Kuftgari. In Kashmir vessels of copper and brass are very effectively inlaid with tin—an art which, like many other decorative arts, appears to have originated in Persia. In the ornamental inlaying of metal surfaces the Japanese display the most extraordinary skill and perfection of workmanship. In the inlaying of their fine bronzes they use principally gold and silver, but for large articles and also for common cast hollow ware (for with them inlaying is common and profuse) commoner metals and alloys are employed. In inlaying bronzes they generally hollow out and somewhat undercut the design, into which the ornamenting metal, usually in the form of wire, is laid and hammered over so as to be firmly inserted. Frequently the famous lacquer work of the Japanese is inlaid with mother-of-pearl and other substances in the same manner as is practised in ornamenting lacquered papier-mâché among Western communities. The Japanese also practise the various methods of inlaying alluded to under DAMASKEENING. The term *Mosaic* (see MOSAIC) is generally applied to inlaid work in hard stones, marble, and glass, but the most important class of mosaics—those which consist of innumerable small separate pieces—do not properly come under the head of inlaying. Inlaid mosaics are those in which colored designs are inserted in spaces cut in a solid ground or basis, such, for example, as the modern Florentine mosaic, which consists of thin veneers of precious colored stones set in slabs of marble. The famous Taj Mahal at Agra is an example of inlaid mosaic in white marble, and the art, carried to that city by a French artist, is still practised by native workmen. *Pietra Dura* is a fine variety of inlaid mosaic in which hard and expensive stones—agate, carnelian, amethyst, and the like—are used in relief in marble. Under the head BUHL WORK (vol. iv. p. 399) will be found a description of the kind of inlaying, principally brass and tortoiseshell, which was introduced and carried to great perfection by André Charles Boule, who gave his name to this particular style of inlaying. Closely allied to buhl work is the more ancient *Tarsia* work or *Marquetry*, which consists of inlaid woods alone. It has been practised from remote times, but came into prominence, for the decoration of furniture, in Italy during the Renaissance epoch, and has continued to be a favorite decorative art, varying with changing tastes and styles, to the present day. From India, under the name of Bombay boxes, comes a variety of minute and elaborate work, inlaid in geometrical patterns on wood. The inlaying materials consist of tin wire, sandal wood, sapan wood, ebony, ivory, and stags' horns, and the effect produced by the combination of minute pieces of these various substances is altogether peculiar and distinctive. Certain kinds of ENAMEL (vol. viii. p. 167) might also be included among the varieties of inlaying.

INNKEEPERS, LAW RELATING TO. By the common law of England innkeepers are under certain peculiar obligations, the most important of which are the duty of supplying accommodation to such travellers as may desire it, and their responsibility for the safety of the goods belonging to persons staying in their inns. An inn is a place "instituted for passengers and wayfaring men," and in a recent case, in which the proprietor of a restaurant was prosecuted for refusing refreshment on demand, it was held that a tavern, or shop for the retail of spirits across the counter, is not within the definition, and that a person resident in the neighborhood of the inn is not a traveller. An innkeeper may be indicted for refusing accommodation to a traveller, who may also of course have a remedy by civil action. To render an innkeeper liable for loss of goods at common law, the following are stated by Chitty (*Law of Contracts*) to be necessary conditions:—(1) that the inn be a "common" inn; (2) that the guest be a traveller or passenger; (3) that the goods or chattels must be in the inn, or at all events under the protection of the innkeeper as such; (4) that there be default on the part of the innkeeper, which is, however, implied in all cases not arising from the negligence of the guest, the act of God, or of the queen's enemies. An innkeeper receiving goods in any other capacity, *e. g.*, as a warehouseman or generally as bailee, or allowing the guest exclusive possession of a room for special purposes, is not liable for loss. Nor is the innkeeper liable for loss of goods by the theft of the guest's servant or companion, or by the negligence of the guest himself. A recent Act, 26 & 27 Vict. c. 4, limits the liability of the innkeeper by the following provisions:—No innkeeper shall be liable to make good loss or injury to goods or property (not being a horse, or other live animal, or gear appertaining thereto, or a carriage) to a greater sum than £30, except in the following cases:—(1) when the loss has been caused by the default or neglect of the innkeeper or his servants; (2) when such goods have been deposited expressly for safe custody with the innkeeper, who may require them to be deposited in a safe or other receptacle and sealed by the person depositing the same. Innkeepers are not entitled to the benefit of the Act if they refuse to receive goods for safe custody, or otherwise prevent their deposit as before provided for, or if they fail to have one copy at least of the first section of the Act exhibited in a conspicuous place in the inn. The liability of innkeepers was recognized in the civil law. On the other hand, the innkeeper has a lien on the goods of his guest for the amount of his bill. It does not extend to the clothes of the guest or justify his personal detention, but it includes articles in the possession of the guest belonging to third persons, at least when they are of a kind that travellers might ordinarily be expected to have. When a professional artist living at an inn had a piano on hire, the innkeeper, who knew it did not belong to her, was held to have no lien thereon. In a recent case the lien has been held to cover a hired piano in the possession of a family staying at an inn. In some American cases it has been held that the possession of a license does not produce, nor does the absence of a license prevent, the liabilities of an innkeeper at common law. An inn is distinguished from a boarding-house in this, that in the latter the guest is under an express contract for a certain time at a certain rate, in the former under an implied contract from day to day. Even if a boarding-house keeper entertains guests in the capacity of an innkeeper, he is not liable as such to his boarding-house guests.

INNOCENT I., pope from 402 to 417, was, according to his biographer in the *Liber Pontificalis*, the son of a man called Innocent of Albano; but according to the more trustworthy Jerome, his father was Pope Anastasius I., whom he was called by the unanimous voice of the clergy and laity to succeed. It was during his papacy that the siege of Rome by Alaric (408) took place, when, according to a doubtful anecdote of Zosimus, the ravages of plague and famine were so frightful, and divine help seemed so far off, that papal permission was granted to sacrifice and pray to the heathen deities; the pope happened, however, to be absent from the city on a mission to Honorius at Ravenna at the time of the sack in 410. He lost no opportunity of maintaining and extending the authority of the Roman see as the ultimate resort for the settlement of all disputes; and his still extant communications to Victricius of Rouen, Exuperius of Toulouse, Alexander of Antioch, and others, as well as his action on the appeal made to him by Chrysostom against Theophilus of Alexandria, show that opportunities of the kind were numerous and varied. He took a decided view on the Pelagian controversy, confirming the decisions of the synod of the province of proconsular Africa held in Carthage in 416, which had been sent to him, and also writing in the same year in a similar sense to the fathers of the Numidian synod of Mileve who, Augustine being one of their number, had addressed him. Among his letters are one to Jerome and another to John, bishop of Jerusalem, regarding annoyances to which the first-named had been subjected by the Pelagians at Bethlehem. He died March 12, 417, and in the Romish Church is commemorated as a confessor along with Saints Nazarius, Celsus, and Victor, martyrs, on July 28. His successor was Zosimus.

INNOCENT II., pope from 1130 to 1143, whose family name was Paparesci, his own baptismal name being Gregory, was probably one of the clergy in personal attendance on the antipope Clement III. (Guibert of Ravenna). By Paschal II. he was created cardinal-deacon. In this capacity he accompained Pope Gelasius II. when driven into France; and by Calixtus II. he was employed on various important missions, such as on that to Worms for concluding the peace concordat with the emperor in 1122, and on that to France in 1123. On February 14, 1130, he was hurriedly chosen to succeed Honorius II.; soon afterwards an opposition asserted itself which issued in the counter-election of Pietro Pierleoni as Pope Anacletus II. Unable to maintain his position in Rome, Innocent took ship for Pisa, and thence sailed by Genoa to France, where the influence of Bernard of Clairvaux readily secured his cordial recognition by the clergy and the court; in October of the same year he was duly acknowledged by Lothaire of Germany and his bishops at the synod of Würzburg. In January, 1131, he had also a favorable interview with Henry II. of England; and in August, 1132, Lothaire undertook an expedition to Italy for the double purpose of being crowned by the pope, and of setting aside the antipope. The coronation ultimately took place in the Lateran church (June 4, 1133), but otherwise the expedition proved abortive. A second expedition by Lothaire in 1136 was not more decisive in its results, and the protracted struggle between the rival pontiffs was terminated only by the death of Anacletus on January 25, 1138. By the Lateran council of 1139, at which Roger of Sicily, Innocent's most uncompromising foe, was excommunicated, peace was at last restored to the church. The remaining years of this pope's life were almost as barren of permanent results as the first had been; his efforts to undo the mischief wrought in Rome by the long schism were almost entirely neutralized by a struggle with the town of Tivoli in which he became involved, and by a quarrel with Louis VII. of France, in the course of which that kingdom was laid under an interdict. Innocent died September 23, 1143, and was succeeded by Celestine II. The doctrinal questions in which he was called on to interfere were those connected with the names of Abelard and Arnold of Brescia.

INNOCENT III., pope from 1198 to 1216, by far the most remarkable of the popes who have reigned under this name, and, if Gregory VII. is excepted, perhaps the greatest of all who have occupied the see of St. Peter, was born at Anagni about 1160. His father, Count Trasimundo of Segni, was a member of the famous house of Conti, from which nine popes, including Gregory IX., Alexander IV., and Innocent XIII., have sprung; his mother, Claricia, belonged to the noble Roman family of Scotti. His own baptismal name was Lothario. After receiving the rudiments of his education in Rome, he studied theology under Peter of Corbeil at Paris, and canon law at Bologna. On his return to Rome in 1181 he became a canon of St. Peter's; and through family influence, combined with the increasing evidence he gave of remarkable ability, his subsequent promotion was rapid. By Gregory VIII. he was appointed one of the subdeacons, and in 1190 (while barely thirty) he was, at the instance of his maternal uncle Clement III., made cardinal-deacon of St. Sergius and St. Bacchus. On the death of Clement (1191), who was succeeded by Celestine III., a member of the rival house of Orsini, Cardinal Lothario was but little employed in church affairs; the unsought leisure which he now possessed he devoted to the composition of three works, two of which have come down to our times. Of these the most remarkable by far is that entitled *De Contemptu Mundi sive de Miseria Humanicæ Conditionis*, written "in not inelegant Latin," full of the best learning of that age, and everywhere manifesting the moral depth, earnestness, and insight, if also the somewhat gloomy and severe temperament, of its author.[1] On the death of Celestine III. (January 8, 1198), Lothario was without a day's delay unanimously chosen to succeed him; his ordination to the priesthood (hitherto he had held only deacon's orders), his episcopal consecration, and his coronation as pope (February 22,

---

[1] The other extant work belonging to this period of Innocent's life is the *Mysteriorum Evangelicæ Legis et Sacramenti Eucharistiæ Libri VI.* The *De Quadripartita Specie Nuptiarum* has not survived.

1198), followed one another in rapid succession. The state of Europe and of the known world at that juncture was such as might have suggested even to a less able and energetic man than Innocent the ambition of once more seeking to obtain for the papacy that absolute supremacy, both spiritual and temporal, in the struggle for which his great predecessor Gregory, more than a century before him, had lost his throne, and, one might almost say, his life. The owner of the crown of Naples (Frederick II., born 1197) was an infant, incapable of protecting his dominions from the numerous adventurers by whom they were overrun; the Lombard republics were at deadly feud with one another, or rent by increasing domestic faction; the empire was convulsed by the struggles of the rival claimants to the throne rendered vacant by the death of Henry VI.; in France Philip Augustus since 1180 had been disgusting his subjects with his tyranny and scandalous vice; at Constantinople the cruel and wicked Alexius III., after dethroning his elder brother, Isaac Angelus, was struggling to maintain his precarious grasp of the sceptre, while the kingdom of Jerusalem, which half a century before had extended along nearly the whole coast of Syria, was now almost entirely confined to the city of Acre. Innocent's first care was to deliver Rome itself from the claims to supreme authority asserted by the prefect, who for many years had been nominated by the emperor, but whom now he compelled to swear allegiance to himself, thus for the first time practically establishing the temporal sovereignty of the bishop of Rome over his own city. In another direction the popular rights in connection with the choice of a "senator" were curtailed. Measures were next taken to free the so-called patrimony of St. Peter from the various German adventurers who, professing to hold of the empire, had divided it amongst them. Markwald of Anweiler, duke of Ravenna, was by a papal army driven from the March of Ancona, with which he had been invested, and compelled to withdraw to the south of Italy; Conrad of Lutzenberg, duke of Spoleto, was driven into Germany; Innocent personally visited Reate, Spoleto, Perugia, Todi, and everywhere was welcomed as sovereign and deliverer. His claim to the sovereignty of the duchy of Tuscany as heir of the countess Matilda, Hildebrand's friend, was successfully asserted next; and on the death of Constantia, widow of Henry VI. of Germany, Innocent, who had been acknowledged by her as liege lord, became, as guardian of the young Frederick II., master of the kingdom of Naples and Sicily. By the help of Walter of Brienne, Diephold of Acerra was compelled to relax his hold of Apulia; and in 1202 the death of Markwald at Palermo removed one of the most vigorous of the many troublers of Italian peace. The rivalry between Philip of Swabia, brother of Henry VI., and the Guelph Otto of Brunswick, for the imperial crown, in the next place offered a favorable opportunity for intervention in German politics after the more immediately pressing affairs of Rome and Italy had been settled. The tardy (but not reluctant) decision finally given (March, 1201) by Innocent in favor of the Guelph did not indeed avert protracted civil war, resulting in humiliation and disaster both to emperor and pope; yet ultimately the murder of Philip (June 21, 1208) paved the way for the peaceful coronation of Otto in the following year, and the long-continued efforts of Innocent seemed to have met with an absolute success when the new emperor not only ratified previously-exacted promises faithfully to maintain the territories, fiefs, and rights of the see of Rome as these had been defined by the see itself, but also renounced even the small share in episcopal elections which had been reserved to the empire in the concordat of Worms. The triumph, it is true, proved a hollow one; Otto soon broke his oath, claiming the kingdom of Apulia as a fief of the empire, and losing no time in commencing a war for the subjugation of Naples. Nor did his excommunication in 1211 result greatly to the advantage of the papacy, except in so far as it strikingly showed how dangerous to the individual was a collision with the supreme spiritual power. The battle of Bouvines (July 27, 1214) finally disposed of the last hopes of Otto, but by it there was left master of the field one who was destined to prove still more formidable in his opposition to ecclesiastical ascendency. The immense influence which the energy, persistence, and political skill of Innocent enabled him to wield throughout the whole duration of his pontificate in the affairs of the empire was equally exemplified in his relations with almost every other state of Christendom. Thus one of his first acts after his accession was to signify his disapproval of the conduct of Philip Augustus of France in dismissing his lawful wife Ingeburga of Denmark. By a rigorous interdict laid upon the kingdom from December, 1199, to September, 1200, the headstrong and refractory king was at last compelled to take her back with all the honor due to the queen of France. So, when in England King John began to persecute the clergy in consequence of their adherence to the cause of Stephen Langton, the papal nominee to the archbishopric of Canterbury (1207), his own excommunication followed forthwith; the kingdom was laid under an interdict (March 24, 1208), his subjects released from their allegiance, and his throne offered to any conqueror, with effects which again were far from being such as Innocent had anticipated, but which could not fail to impress the minds of the men of that time with a new and deep sense of the vigor and far-reaching power of the vicars of Christ. In Castile, in Portugal, in Leon, in Navarre, in Denmark, Bohemia, Poland, Hungary, the same story repeats itself, with equal distinctness, if with less prominent results. Another outlet of the zeal and ambition of Innocent was found in the fifth crusade, the leading events of which, including the pact with Venice and the fall of Constantinople, have been elsewhere related (vol. vi. p. 555–6). In the west, also, a new crusade against heretics was set on foot with relentless energy, which has been described in the article ALBIGENSES. The principles upon which such enterprises ought to be conducted were formulated under the presidency of Innocent at the fourth Lateran council (1215). It was there decreed that all rulers should promise to tolerate no heretics within their dominions, and that any prince who should refuse to comply with an injunction of the church to purge his dominions of heresy was to be punished with excommunication, and in case of contumacy to be deposed,—if necessary, by force of arms. To those who should take part in such application of armed force when declared necessary, immunities similar to those enjoyed by the Eastern crusaders were guaranteed. At the same time very stringent laws were made with reference to the Jews. Their disability to hold any public appointment of trust was declared, and they were prohibited from at any time wearing Christian apparel, and also from appearing in public at all during Holy Week. This council was held by Innocent in the full consciousness of his approaching dissolution, which took place at Perugia on July 16, 1216. He was succeeded by Honorius III. Apart from his other claims to fame as a sovereign and statesman of remarkable breadth of view, unity of purpose, and boldness of action, Innocent deserves notice as a canonist and as a preacher. His decisions in canon law are characterized by a learning and an acuteness which have made him an important authority. The decretals of the first three years of his pontificate were collected by Rainer of Pomposi, and afterwards Bernardus Compostellanus undertook the editing of those of the first nine years, which appeared in a collection known as the *Compilatio Romana*. This, however, contained some spurious documents, which were eliminated from the *Compilatio tertia*, brought down by Petrus Callivacinus to the twelfth year, and sent to the university of Bologna. The *Compilatio quarta*, published shortly after his death, contains the bulls and briefs of the closing six years. Some indication of Innocent's power as a preacher, which is known to have been great, can still be found in his extant sermons; while fully partaking of the curious artificiality and mannerism of the period, they abound in passages of fervid eloquence, and are everywhere characterized by deep religious and moral feeling.

For the works of Innocent III., see Migne, *Patrol. Curs. Compl.*, vols. 214–217. For his life and pontificate, vol. v. of Milman's *Latin Christianity*, may be consulted; also Jorry, *Histoire du Pape Innocent III.*, Paris, 1853; Deutsch, *Papst Innocenz III. u. sein Einfluss auf die Kirche*, 1876; Wattenbach, *Gesch. de röm. Papstthums*, 1876.

INNOCENT IV., Sinibaldo de Fieschi, pope from 1243 to 1254, belonged to one of the first families of Genoa, and, educated at Parma and Bologna, passed for one of the best canonists of his time. He had for his immediate predecessor Celestine IV., who, however, was pope for eighteen days only, and therefore the events of Innocent's pontificate practically link themselves on to those of the reign of Gregory IX. It was on occasion of Innocent's election (June 28, 1243) that Frederick II. is said to have remarked that he had lost the friendship of a cardinal and gained the enmity of a pope; the letter which he wrote, however, expressed in respectful terms the hope that an amicable settlement of the differences between the empire and the papal see might be reached. The negotiation which shortly afterwards began with this object speedily proved abortive, Frederick being unable to make the absolute submission to the pope's demands which was required of him. Finding his position in Rome insecure, Innocent secretly withdrew in the summer of 1244 to Genoa, and thence to Lyons, where he summoned a general council which met in 1245 and deposed Frederick. The agitation caused by this act throughout Europe terminated only with Frederick's death in 1250, which permitted the pope to return, first to Perugia, and afterwards in 1253 to Rome. The remainder of his life was largely devoted to schemes for compassing the overthrow of Manfred, the natural son of Frederick II., whom the towns and the nobility had for the most part received as his father's successor. It was on a sick bed at Naples that Innocent heard of Manfred's victory at Foggia, and the tidings are said to have precipitated his death (December 7, 1254). His learning gave to the world an *Apparatus in quinque libros decretalium*, which is highly spoken of; but essentially Innocent IV. was a small-souled man, whose avarice, cowardice, cunning, and vindictiveness suggest a striking contrast with Innocent III., whose character and career, if his selection of a name may be taken as an indication, he seems to have admired and sought to follow. He was succeeded by Alexander IV.

INNOCENT V., pope from January 20 to June 22, 1276, was a native of Tarantasia in Burgundy, where he was born in 1225. In early life he joined the Dominican order, in which he acquired great fame as a preacher. The only noteworthy feature of his brief and uneventful pontificate was the practical form assumed by his desire for union with the Eastern Church. He was proceeding to send legates to the Greek emperor in connection with the recent decisions of the council of Lyons when he died. He was the author of several works in philosophy, theology, and canon law, including commentaries on the Pauline epistles and on the *Sentences* of Peter of Lombardy, and is sometimes referred to as "famosissimus doctor." His predecessor was Gregory X., and he was succeeded by Hadrian V.

INNOCENT VI., Stephen Aubert, pope at Avignon from 1352 to 1362, the successor of Clement VI., was a native of the diocese of Limoges, and, after having taught civil law at Toulouse, became bishop successively of Noyon and of Clermont. In 1342 he was raised to the dignity of cardinal. On the death of Clement VI., after the cardinals had each bound himself by a solemn agreement as to a particular line of policy should he be elected, Aubert was chosen (December 18, 1352); one of the first acts of his pontificate was to declare the paction to have been illegal and null. His subsequent policy compares favorably with that of the other Avignon popes. He brought about many needed reforms in the administration of church affairs, and by his legate, Cardinal Albornoz, who was accompanied by Rienzi, he sought to restore order in Rome, where in 1355 Charles IV. was with his permission crowned, after having previously come under an oath that he would quit the city on the day of the ceremony. It was largely through the exertions of Innocent that the peace of Bretigny (1360) between France and England was brought about. During this pontificate also John Palæologus offered to submit the Greek church to the Roman see on condition of assistance being rendered him against John Cantacuzenus. The resources at the disposal of the pope, however, were all required for exigencies nearer home, and the offer was declined. Innocent was a liberal patron of letters, and, if the extreme severity of his measures against the Fraticelli be kept out of account, had a deservedly high reputation for justice and mercy. He died September 12, 1362, and his successor was Urban V.

INNOCENT VII., Cosimo de Migliorati, pope from 1404 to 1406, was a native of Solmona in the Abruzzi, and early distinguished himself by his learning both in civil and in canon law. By Urban VI., he was called to the papal court, and entrusted with various responsible offices, being finally promoted to the archbishopric of Ravenna, and afterwards to the bishopric of Bologna. Boniface IX. made him cardinal, and employed him as legate in several delicate and important missions. On the death of Boniface, Migliorati was unanimously chosen (October 17, 1404) to succeed him, after each of the cardinals had bound himself by a solemn obligation to employ all lawful means for the restoration of the church's unity in the event of his election, and even to resign the papal dignity should that be considered necessary to this end. The election was resisted at Rome by the Ghibelline party, but peace was maintained by the aid of Ladislaus of Naples, who thus laid Innocent under embarrassing obligations, from which he freed himself at the earliest possible moment. The assassination of some leading members of the city party by Ludovico Migliorati (a nephew of Innocent) and his friends compelled the pope to take refuge, in August, 1405, at Viterbo, whence he did not return until January of the following year. These troubles furnished him with a pretext, of which he was not unwilling to avail himself, for postponing the meeting of a general council which was urged by Charles of France, the university of Paris, Rupert of Germany, and John of Castile, as the only means of healing the schism which had prevailed so long. It is hardly necessary to say that he showed no favor to the proposal that he as well as the antipope Benedict XIII. should resign in the interests of peace. He died somewhat suddenly at Rome on November 6, 1406; there is no evidence for the truth of the allegation that his death was not due to natural causes. His successor was Gregory XII.

INNOCENT VIII., Giovanni Battista Cibo, pope from 1484 to 1492, was born at Genoa (1432), and was the son of a man of senatorial rank. His early years were spent at the Neapolitan court, and subsequently he went to Padua and Rome for his education. In the latter city the influence of his friends procured for him, from Paul II., the bishopric of Savona, and in 1473 he was made cardinal by Sixtus IV., whom he succeeded on August 29, 1484. Shortly after his coronation he addressed a fruitless summons to Christendom to unite in a crusade against the infidels; the amount of his own zeal may in some degree be estimated from the fact that in 1489, in consideration of a yearly sum of 40,000 ducats and a gift of the spearhead which had pierced the Saviour's side, he consented to favor the sultan Bajazet II. by detaining his fugitive brother in close confinement in the Vatican. In 1486 Henry VII. of England was declared to be the lawful holder of the English crown by the threefold right of conquest, inheritance, and popular choice. Innocent in his bull "Summis desiderantes" (5th December, 1484) instigated very severe measures against magicians and witches in Germany; the principles enunciated by him were afterwards embodied in the *Malleus maleficarum* (1487). He it was also who in 1487 appointed Torquemada to be grand inquisitor of Spain; he also urged a crusade against the Waldensians, offering plenary indulgence to all who should engage in it. In 1486 he prohibited, on pain of severe ecclesiastical censures, the reading of the nine hundred propositions of Pico Mirandola. An important event of his pontificate was the fall of Granada (January, 1492), which was celebrated in the Vatican with great rejoicings. He died July 25, 1492, leaving behind him numerous children ("Octo Nocens pueros genuit, totidemque puellas; Hunc merito poterit dicere Roma patrem"), towards whom his nepotism had been as lavish as it was shameless. His successor was Alexander VI.

INNOCENT IX. succeeded Gregory XIV. on October 29, 1591, and died on December 30 of the same year. His pontificate was unimportant. Clement VIII. was his successor.

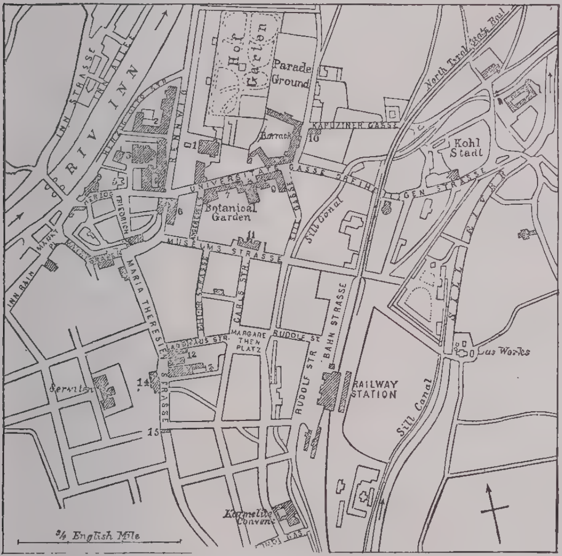
INNOCENT X., Giovanni Battista Pamphili, pope from 1644 to 1655, was born at Rome in 1574, attained the dignity of cardinal in 1629, and through French influence was chosen to succeed Urban VIII. on September 15, 1644. Throughout his reign the influence exercised over him by Olympia Maidalchina, his deceased brother's wife, was very great, and such as to give rise to gross scandal, for which, however, there appears to have been no adequate ground. He naturally enough objected to the conclusion of the peace of Westphalia, against which his nuncio in his name vainly protested, and against which he issued the bull "Zelo domus Dei" in November, 1648. The most important of his doctrinal decisions was his condemnation of the five Jansenist propositions in 1653. The avarice of his female counsellor gave to his reign a tone of oppression and sordid greed which probably it would not otherwise have shown, for personally he was not without noble and reforming impulses. He died January 5, 1655, and was succeeded by Alexander VII.

INNOCENT XI., Benedetto Odescalchi, pope from 1676 to 1689, was born at Como in 1611, studied law at Rome and Naples, held successively the offices of protonotary, president of the apostolic chamber, commissary of the Marca di Roma, and governor of Macerata; in 1647 Innocent X. made him cardinal, and he afterwards successively became legate to Ferrara and bishop of Novara. In all these capacities the simplicity and purity of character which he displayed had combined with his unselfish and openhanded benevolence to secure for him a high place in the popular affection and esteem; and two months after the death of Clement X. he was (September 21, 1676), in spite of French opposition, chosen his successor. He lost no time in declaring and practically manifesting his zeal as a reformer of manners and a corrector of administrative abuses. He sought to abolish sinecures and to put the papal finances otherwise on a sound footing; beginning with the clergy, he sought to raise the laity also to a higher moral standard of living. Some of his regulations with the latter object, however, may raise a smile as showing more zeal than judgment. In 1679 he publicly condemned sixty-five propositions, taken chiefly from the writings of Escobar, Suarez, and the like, as "propositiones laxorum moralistarum," and forbade any one to teach them under penalty of excommunication. Personally not unfriendly to Molinos, he nevertheless so far yielded to the enormous pressure brought to bear upon him as to confirm in 1687 the judgment of the inquisitors by which sixty-eight Molinist propositions were condemned as blasphemous and heretical. His pontificate was marked by the prolonged struggle with Louis XIV. of France on the subject of the so-called "Gallican Liberties," and also about certain immunities claimed by ambassadors to the papal court. He died after a long period of feeble health on August 12, 1689. Hitherto repeated attempts at his canonization have invariably failed, the reason popularly assigned being the influence of France. The fine moral character of Innocent has been sketched with much artistic power as well as with historical fidelity by Mr. Robert Browning in *The Ring and the Book*. Innocent XI. was succeeded by Alexander VIII.

INNOCENT XII., Antonio Pignatelli, pope from 1691 to 1700, was the successor of Alexander VIII. He came of a distinguished Neapolitan family, and was born March 13, 1615. Educated at the Jesuit college in Rome, he in his twentieth year became an official of the court of Urban VIII.; under successive popes he served as nuncio at Florence and Vienna and in Poland; and by Innocent XI. he was made cardinal (1681) and archbishop of Naples. Immediately after his election (July 12, 1691) he declared against the nepotism which had too much and too long been one of the greatest scandals of the papacy; the bull "Romanum decet Pontificem," issued in 1692, prohibited popes in all times coming from bestowing estates, offices, or revenues on any relative; at the same time he sought to check the simoniacal practices of the apostolic chamber, and in connection with this to introduce a simpler and more economical manner of life into his court. He introduced various much-needed reforms into the States of the Church, and for the better administration of justice erected the Forum Innocentianum. In 1693 he compelled the French bishops to retract the four propositions relating to the "Gallican Liberties" which had been formulated by the assembly of 1682. In 1699 he decided in favor of Bossuet in his controversy with Fénelon about the *Explication des Maximes des Saints sur la Vie Intérieure* of the latter. His pontificate contrasted with that of a series of predecessors in having marked leanings towards France instead of Germany. This benevolent, self-abnegating, and pious pope died on September 27, 1700, and was succeeded by Clement XI.

INNOCENT XIII., Michael Angelo Conti, pope from 1721 to 1724, was born in 1655, and became cardinal under Clement XI. in 1706. From 1697 to 1710 he acted as papal nuncio to the kingdom of Portugal, where he is believed to have formed those unfavorable impressions of the Jesuits which afterwards influenced his conduct towards them. In 1721 his high reputation for ability, learning, purity, and a kindly disposition secured his election to succeed Clement XI. His pontificate was prosperous, but comparatively uneventful. He prohibited the Jesuits from prosecuting their mission in China, and ordered that no new members should be received into the order. This indication of his sympathies encouraged some French bishops to approach him with a petition for the recall of the bull "Unigenitus" by which Jansenism had been condemned; the request, however, was peremptorily denied. Innocent XIII., like his predecessor, showed much favor to the English Pretender "James III.," and liberally supported him. He died March 7, 1724, and was succeeded by Benedict XIII.

INNSBRUCK, or Innspruck (18,000), the chief town of Tyrol, Austria, is situated on the right bank of the Inn, not far from its junction with the Sill, in a beautiful valley surrounded by lofty mountains, which seem to overhang the town. It is connected with its suburbs on the left bank of the stream by three bridges. The old wooden bridge, which was the scene of a fierce struggle between the Tyrolese and the Bavarians in 1809, was replaced in 1871–72 by a handsome iron structure, and the banks of the Inn have, during the last few years, been widened and planted with trees. Innsbruck is the seat of the law courts and the usual administrative offices for the district of Tyrol and Vorarlberg. The town has broad streets, with four open places. The houses are handsome; many of those in the old town date from the 17th and 18th centuries, and are built in the Italian style, adorned with frescoes, and having arcades beneath used as shops. The Franciscan or court church (1553–1563), in the Renaissance style, contains several works of art, of which the chief is the imposing cenotaph of the emperor Maximilian I. This monument of art, one of the most important on the Continent, represents the emperor kneeling in prayer on a marble sarcophagus, surrounded by twenty-eight colossal bronze statues of his ancestors; while on the sides of the sarcophagus there are twenty-four reliefs, depicting the chief events in Maximilian's life. Alexander Colin executed most of the reliefs (see vol. vi. p. 127); and Gilg Sesselschreiber, court painter, had the general superintendence of the work, and designed many of the statues. In the same church are the monuments of the patriots Hofer, Haspinger, and Speckbacher, and one in memory of the Tyrolese who fell in defence of their country between 1796 and 1809. The silver chapel of the church contains a silver Madonna and altarpiece, and the graves of Archduke Ferdinand II. and his wife Philippa. In this church Christina of Sweden, daughter of Gustavus Adolphus, publicly adopted the Roman Catholic faith in 1654. Other churches worthy of note are the Pfarr-church, the Jesuits' church, the Serviten church, and St. John's of Nepomuk. There are numerous monastic institutions, including a Jesuits' college, and a Capuchin convent, begun in 1593 as the first of the order in Germany. The university, founded in 1672 and, after being twice suspended, finally reinstituted in 1826, had in 1880–81 a teaching staff of 76, and (1879–80) 607 students. It possesses a fine library, and exhibitions to the annual value of £1200. The Ferdinandeum, an interesting national museum, was founded in 1845, and is maintained by private enterprise. The other chief buildings are the palace, completed in 1771, the theatre, the post-office, the landhaus, town-house, and other official buildings, and several schools and benevolent institutions. The Golden Roof (Goldne Dachl) is prominent on the front of a mansion built in 1425 at great expense by Frederick of the Empty Pockets, as a practical refutation of his nickname. Among the several monuments in the town are St. Anna's pillar, erected in 1706 to commemorate the repulse of the French and Bavarians in 1703; the fountain, with a bronze statue of Duke Rudolf IV., raised in 1863–77 in memory of the five hundredth anniversary of the union of Tyrol with Austria; statues of the archduke Leopold V. and of Walter von der Vogelweide; and the triumphal arch erected in 1765, on the occasion of the marriage of the emperor Leopold II. to the infanta Maria Ludovica. The manufactures of Innsbruck comprise woollen and cotton goods, stained glass, leather and machinery; and there is considerable transit trade between Italy and Austria. The population in 1869 was 16,324; but in 1879 it was estimated at about 18,000, with a garrison of 2000 men.



Plan of Innsbruck.

1. National Theatre.
2. Town-house, Custom-house.
3. Pfarr-church.
4. Burg or Palace.
5. Goldne Dachl.
6. Franciscan or Court Church.
7. University.
8. Jesuits' Church.
9. Jesuits' College.
10. Capuchin Monastery.
11. Museum.
12. Landhaus.
13. Post-Office.
14. Serviten Church.
15. Triumphal Arch.

The ancient name of the town was Œni Pons or Œnipontum, of which Innsbruck (Bridge of Inn) is the German equivalent. It received town privileges in 1234 from Duke Otto I. of Meran; from that date till about 1665 it was the capital of the Tyrolese counts; and after the union of Tyrol with Austria in 1363 it became a favorite residence of the emperors. In 1552 Maurice of Saxony surprised and took Innsbruck, almost capturing the Emperor Charles V., to whom a mutiny among Maurice's troops afforded time for a hasty flight. In the war of the Spanish succession, and again in the patriotic Tyrolese wars at the beginning of the 19th century, Innsbruck suffered severely. During the commotions of 1848, it was the temporary refuge of the Emperor Ferdinand.

INNS OF COURT. The Inns of Court and Chancery are voluntary non-corporate legal societies seated in London, having their origin about the end of the 13th and the commencement of the 14th century.

Dugdale (*Origines Juridiciales*) states that the learned in our laws were anciently persons in holy orders, the justices of the king's court being bishops, abbots, and the like. But in 1207 the clergy were prohibited by canon from acting in the temporal courts. The result proving prejudicial to the interests of the community, a commission of inquiry was issued by Edward I. (1290), and this was followed up (1292) by a second commission, which among other things directed that students "apt and eager" should be brought from the provinces and placed in proximity to the courts of law now fixed by Magna Charta at Westminster. These students were accordingly located in what became known as the Inns of Court and Chancery, the latter designated by Fortescue (*De Laudibus*) as "the earliest settled places for students of the law," the germ of what Sir Edward Coke subsequently spoke of as our English juridical university. In these Inns of Court and Chancery, thus constituted, and corresponding to the ordinary college, the students, according to Fortescue, not only studied the laws and divinity, but further learned to dance, sing, and play instrumental music, "so that these hostels, being nurseries or seminaries of the court, were therefore called Inns of Court."

Stow in his *Survey* (1598) says: "There is in and about this city a whole university, as it were, of students, practisers or pleaders, and judges of the laws of this realm;" and he goes on to enumerate the several societies, fourteen in number, then existing, corresponding nearly with those recognized in the present day, of which the Inns of Court, properly so called, are and always have been four, namely, *Lincoln's Inn*, with the subordinate Inns of Chancery, Furnival's Inn and Thavie's Inn; the *Inner Temple*, with Clifford's Inn and Clement's Inn; the *Middle Temple*, with New Inn; and *Gray's Inn*, with Staple's Inn and Barnard's Inn. In addition to these may be specified *Serjeant's Inn*, a society composed solely of serjeants-at-law, which, however, ceased to exist in 1877. Besides the

Inns of Chancery above enumerated, there were others, such as Lyon's Inn, which was pulled down as recently as 1868, and Scrope's Inn and Chester or Strand Inn, spoken of by Stow, which have long been removed, and the societies to which they belonged have disappeared. The four Inns of Court stand on a footing of complete equality, no priority being conceded to or claimed by one inn over another. Their jurisdictions and privileges are equal, and upon affairs of common interest the benchers of the four inns meet in conference. From the earliest times there has been an interchange of fellowship between the four houses; nevertheless the Middle Temple and Lincoln's Inn, and the Inner Temple and Gray's Inn, have maintained a closer alliance.

The members of an Inn of Court consist of benchers, barristers, and students. The benchers are the governing bodies of the inns, and are composed of the senior members, designated also more formally "masters of the bench." They are self-elected, and unrestricted as to numbers; usually, but not invariably, a member of an inn, on attaining the rank of queen's counsel, is invited to the bench. Other members of long standing are also occasionally chosen, but no member by becoming a queen's counsel or by seniority of standing acquires the right of being nominated a bencher. The benchers thus elected vary in number from twenty in Gray's Inn to seventy and upwards in Lincoln's Inn and the Inner Temple. The powers of the benchers are practically without limit within their respective societies; their duties, however, are restricted to the superintendence and management of the concerns of the inn, the admission of candidates as students, the calling of them to the bar, and the exercise of discipline generally over the members. The judges of the superior courts are the visitors of the inns, and to them alone can an appeal be had when either of the societies refuses to call a member to the bar, or to reinstate in his privileges a barrister who has been disbarred for professional or other misconduct. The meetings of the benchers are variously denominated a "parliament" in the Inner and Middle Temples, a "pension" in Gray's Inn, and a "council" in Lincoln's Inn. The presiding or chief officer is the treasurer, one of the benchers, who is elected annually to that dignity. Other benchers fulfil the duties of master of the library, master of the walks or gardens, dean of the chapel, and so forth, while others are readers, whose functions are referred to below. Under the term barrister are included generally all those members of an Inn of Court who, after due probation, and being at least twenty-one years of age, have been called to that rank by the benchers of the inn of which they have been students. For a notice of these the reader is referred to the article BARRISTERS (vol. iii. p. 340), but some further details respecting their connection with these societies may be fitly given here. Each inn confers this status or degree on its own members only. The grade of barrister comprehends the attorney-general and solicitor-general (appointed by and holding office solely at the will of the Government of the day) who rank as the heads of the profession, queen's counsel, and ordinary practitioners, sometimes technically known as "utter barristers." There is also the practitioner "below the bar," the lowest in the ranks of the forensic hierarchy, who limits his practice to those special branches of the law designated pleading and conveyancing, and is precluded by the fact of his not having been "called" from appearing in court.

The usages of the different inns varied somewhat formerly in regard both to the term of probationary studentship enforced and to the procedure involved in a call to the bar. In the present day complete uniformity is observed in all respects, the entrance examination, the course of study, and the examinations required to be passed on the completion of the curriculum being identical and common to all the inns alike. When once called to the bar, the barrister is left to follow his own will in regard to entering into active practice or with respect to the special branch of the law he may elect to pursue, no hindrance beyond professional etiquette limiting his freedom of action in any way; so also members may on application to the benchers, and on payment of arrears of dues (if any), leave the society to which they belong, and thus cease altogether to be members of the bar likewise. Barristers rank as esquires, and are privileged from arrest whilst in attendance on the superior courts and on circuit, and also from serving on juries. They enjoy unfettered freedom of speech, though this confers no right to utter slander. On the other hand, a barrister has no legal remedy for the recovery of his fees, and it is not competent for him to enter into any contract for payment by his client with respect to litigation. A member of an Inn of Court retains his name on the lists of his inn for life by means of a small annual payment varying from £1 to £5, which at one or two of the inns is now compounded for by a fixed sum taken at the call to the bar. A distinctive dress is worn by barristers when attending the courts, consisting of a stuff-gown, exchanged for one of silk when the wearer has attained the rank of queen's counsel, both classes also having wigs dating in pattern and material from the 18th century. Those who practise below the bar as pleaders or conveyancers are under the necessity of taking out a certificate, which is granted for one year only, but is renewable, and is subject to a small payment. This certificate is issued by the benchers of the Inn of Court of which the practitioner is a member, and is given to those only who are qualified to be called to the bar.

During the reign of Edward III. the Inns of Court and Chancery, based on the collegiate principle, prospered under the supervision and protection of the crown. In 1381 Wat Tyler invaded the Temple, and in the succeeding century (1450) Jack Cade meditated pulling down the Inns of Court and killing the lawyers. It would appear, moreover, that the inmates of the inns were themselves at times disorderly and in conflict with the citizens. Fortescue (*circa* 1464) describing these societies thus speaks of them: "There belong to the law ten lesser inns, which are called the Inns of Chancery, in each of which there are one hundred students at least, and in some a far greater number, though not constantly residing. After the students have made some progress here they are admitted to the Inns of Court. Of these there are four, in the least frequented of which there are about two hundred students. The discipline is excellent, and the mode of study well adapted for proficiency." This curriculum had probably existed for two centuries before Fortescue wrote, and continued to be enforced certainly down to the time of Sir Thomas More (1498) and of Chief Justice Dyer (1537), and yet later to that of Sir Edward Coke (1571). From this time, however, the attorneys were gradually closing the doors of the Inns of Chancery against students for the bar; and these preparatory schools of law, once the stepping stones to the Inns of Court (who directed their studies), have long since severed their relations with the bar and with legal education, and are now of no account whatever in connection with the law, their members being chiefly, though not entirely, solicitors meeting solely for convivial purposes. By the time of Sir Matthew Hale (1629) the custom for law students to be first entered to an Inn of Chancery before being admitted to an Inn of Court had become obsolete, and thenceforth the Inns of Chancery have been entirely abandoned to the attorneys. Stow in his *Survey* succinctly points out the course of reading enforced at the end of the 16th century. He says that the Inns of Court were replenished partly by students coming from the Inns of Chancery, who went thither from the universities and sometimes immediately from grammar schools; and, having spent some time in studying the first elements of the law, and having performed the exercises called "bolts," "moots," and "putting of cases," they proceeded to be admitted to, and become students in, one of the Inns of Court. Here continuing for the space of seven years or thereabouts, they frequented readings and other learned exercises, whereby, growing ripe in the knowledge of the laws, they were, by the general consent either of the benchers or of the readers (who down to 1664 enjoyed a special privilege in this respect), called to the degree of barrister, and so enabled to practise in chambers and at the bar. There is thus abundant evidence that ample provision for legal study was formerly made, and that this continued with more or less vigor down to nearly the commencement of the 18th century. A languor similar to that which affected the church and the universities then gradually supervened, until the fulfilment of the merest forms sufficed to confer the dignity of advocate and pleader. This was maintained until recent years, when (from 1845) the necessity for suitable training of young men aspiring to forensic honors has again become recognized, and steps have been taken for reviving and extending the ancient discipline and course of study, bringing them into harmony with modern ideas and requirements.

In the present day the four Inns of Court have combined in framing and enforcing regulations having for their end a preliminary or matriculation examination prior to admission to an inn, the keeping of terms, the attendance at lectures and private classes, and finally an examination preparatory to the call to the bar, which, as at the universities, is divided into an honor and a simple pass examination, the former carrying with it certain studentships of some pecuniary value and certificates of honor. The scope of the examinations is tolerably wide, and includes jurisprudence (with international law, public and private), the Roman civil law, constitutional law and legal history, common law, equity, the law of real and personal property, and criminal law. These studies, and the examinations consequent upon them, are superintended and controlled by a council of legal education consisting of twenty benchers nominated in equal numbers by each inn, and by a permanent committee of education and examination consisting of eight members, appointed by and taken from the council itself. A body of examiners has been likewise constituted, whose payment, together with the attendant expenses of the council, is provided for by annual contributions, in certain fixed proportions, made by the four inns. The arrangements in force would appear, however, to be regarded as tentative only, several attempts having been made to carry out a more systematic scheme of education, to be developed eventually into a regular legal university. The assistance of the legislature to this end has even been sought, but as yet without result, in the shape of a statutory enactment. The fees payable at the different inns vary from £136, 11s. 10d. at Gray's Inn to £154, 1s. 3d. at the Middle Temple. These sums cover all expenses from admission to an inn to the call to the bar, but the addition of tutorial and other expenses may augment the cost of a barrister's legal education to £400 or £500. The period of study prior to call has now become limited to twelve terms, equivalent to about three years. In the case of solicitors, however, the regulations have been altered in 1881 so as to enable them to be called after the lapse of one year.

It has been seen that the studies pursued in ancient times were conducted by means of "readings," "moots," and "bolts." The *readings* were from the very first deemed of vital importance, and were delivered in the halls with much ceremony; they were frequently regarded as authorities and cited as such at Westminster in argument. Some statute or section of a statute was selected for analysis and explanation, and its relation to the common law pointed out. Many of these readings, dating back to Edward I., are extant, and well illustrate the importance of the subjects and the exhaustive and learned manner in which they were treated by the able, experienced men upon whom this duty was cast. The function of "reader" involved the holder in very weighty expenses, chiefly by reason of the profuse hospitality dispensed,—a constant and splendid table being kept during the three weeks and three days over which the readings extended, to which were invited the nobility, judges, bishops, the officers of state, and sometimes the king himself. In 1688 the readers were paid £200 for their reading, but by that time the office had become a sinecure. In the present day the readership is purely honorary and without duties. The privilege formerly assumed by the reader of calling to the bar was taken away in 1664 by an order of the lord chancellor and the judges. *Moots* were exercises of the nature of formal arguments on points of law raised by the students and conducted with much care under the supervision of a bencher and two barristers sitting as judges in the halls of the inns. *Bolts* were of an analogous character, though deemed inferior to moots. Both had fallen into complete desuetude until lately, when the society of Gray's Inn has revived mootings, it is understood with some success.

In the early history of the inns discrimination was exercised in regard to the social status of candidates for admission to them. Ferne, a writer of the 16th century, referred to by Dugdale, states that none were admitted into the houses of court except they were gentlemen of blood. So also Pliny, writing in the 1st century of the Christian era (*Letters*, ii. 14), says that before his day young men even of the highest families of Rome were not admitted to practice except upon the introduction of some man of consular rank. But he goes on to add that all barriers were then broken down, everything being open to everybody—a remark quite applicable to the bar of England and elsewhere in the present day. It may here be noted that no dignity or title confers any rank at the bar. A privy councillor, a peer's son, a baronet, the speaker of the House of Commons, or a knight, all rank at the bar merely according to their legal precedence. Formerly orders were frequently issued both by the benchers and by the crown on the subject of the dress, manners, morals, and religious observances of students and members. No such interference with the liberty of the subject is now recognized in the inns of court; and, although there is some semblance of a collegiate discipline maintained, this is restricted to the dining in hall, where many ancient usages survive, and to the closing of the gates of the inns at night.

Each inn maintains a chapel, with the accompaniment of preachers and other clergy, the services being those of the Church of England. The Inner and the Middle Temple have joint use of the Temple church, a fabric of high antiquity and much dignity. The chapels of Lincoln's Inn and Gray's Inn are also very interesting. The office of preacher is usually filled by an ecclesiastic of learning and repute chosen by the benchers. The principal functionary of this rank in connection with the Temple church is, however, constituted by letters patent by the crown without episcopal institution or induction, enjoying, nevertheless, no authority independently of the benchers. He bears the title of Master of the Temple.

It has already been stated, on the authority of Fortescue, that the students of the Inns of Court learned to dance, sing, and play instrumental music; and those accomplishments found expression no doubt in the "masques" and "revels" for which the societies formerly distinguished themselves, especially the Inner Temple and Gray's Inn. These entertainments were of great antiquity and much magnificence, involving very considerable expense. Evelyn (*Diary*) speaks of the revels at the Middle Temple as an old and riotous custom, having relation neither to virtue nor to policy. The last revel appears to have been held at the Inner Temple in 1734, to mark the occasion of the elevation of Lord Chancellor Talbot to the woolsack. The plays and masques performed were sometimes repeated elsewhere than in the hall of the inn, especially before the sovereign at court. A master of the revels was appointed, commonly designated Lord of Misrule, whose authority in making the necessary arrangements was paramount. Abundant information as to the scope and nature of these entertainments has come down to us: one of the festivals is minutely described by Gerard Leigh in his *Accedence of Armorie*, 1612; and a tradition ascribes the first performance of Shakespeare's *Twelfth Night* to a revel held in the Middle Temple hall in February, 1601. At the present day no entertainments are given; excepting on very rare occasions the hospitality of the inns has ceased to find expression save in the "Grand Day" held once in each of the four terms, when it is customary for the judges and other distinguished visitors to dine with the benchers (who sit apart from the barristers and students on a dais in some state), and "Readers' Feasts," on both which occasions extra commons and wine are served to the members attending.

The *Inner* and the *Middle Temple*, so far as their history can be traced back, have always been separate societies. Fortescue, writing between 1461 and 1470, makes no allusion to a previous junction of the two inns. Dugdale (1671) speaks of the Temple as one society, and states that the students so increased in number that at length they divided into two bodies, becoming the Inner and Middle Temple respectively. He does not, however, give any authority for this statement, or furnish the date of the division. The first reliable mention of the Temple as an inn of court is to be found in the *Paston Letters*, where, under date November, 1440, the Inner Temple is spoken of as a college, as is also subsequently the Middle Temple. The Temple, as the name would serve to indicate, was the seat in England of the famous monastic order known as the Knights Templars, on whose suppression in 1312 it passed with other of their possessions to the crown, and after an interval of some years, to the Knights Hospitallers of St. John, of Jerusalem, who in the reign of Edward III. demised the mansion and its surroundings to certain professors of the common law who came from Thavie's Inn. Notwithstanding the destruction of the muniments of the Temple by fire or by popular commotion, sufficient testimony is attainable to show that in the reigns of Edward III. and Richard II. the Temple had become the residence of the legal communities which have since maintained there a permanent footing. The two societies continued as tenants to the Knights Hospitallers of St. John until the dissolution of the order in 1539; they then became the lessees of the crown, and so remained until 1609, when James I. made a grant by letters patent of the premises in perpetuity to the benchers of the respective societies on a yearly payment by each of £10, a payment which has long ceased to be made, having been bought up in the reign of Charles II. In this grant the two inns are described as "the Inner and the Middle Temple or New Temple," and as "being two out of those four colleges the most famous of all Europe" for the study of the law. Excepting the church, nothing now remains of the edifices belonging to the Knights Templars, the present buildings having been almost wholly erected since the reign of Queen Elizabeth or since the Great Fire, in which the major part of the Inner Temple perished. The church, a noble structure, has been in the joint occupation of the Inner and Middle Temple from time immemorial,—the former taking the southern and the latter the northern half. The round portion of the church was consecrated in 1185, the nave or choir in 1240. It is the largest and most complete of the four remaining round churches in England, and is built on the plan of the church of the Holy Sepulchre at Jerusalem. Narrowly escaping the ravages of the fire of 1666, this beautiful building remains to this day one of the most perfect specimens of early Gothic architecture in England, and is maintained in the highest order in respect not merely to the edifice itself but to the services conducted within its walls. In former times the lawyers awaited their clients for consultation in the Round Church, as similarly the serjeants-at-law were accustomed to resort to St. Paul's Cathedral, where each serjeant had a pillar assigned him.

The *Inner Temple*, comprehending a hall, parliament chamber, library, and other buildings, occupies the site of the ancient mansion of the Knights Templars, built about the year 1240, and has from time to time been more or less re-erected and extended, the most recent changes in this direction dating from 1870, when the present handsome range of buildings, including a new dining hall, was completed. The library owes its existence to William Petyt, keeper of the Tower Records in the time of Queen Anne, who was also a benefactor to the library of the Middle Temple. The greatest addition by gift was made by the Baron Masseres in 1825. The number of volumes now in the library is 30,000, arranged in suitable rooms adjoining the hall. Of the Inns of Chancery belonging to the Inner Temple *Clifford's Inn* was anciently the town residence of the Barons Clifford, and was demised in 1345 to a body of students of the law. *Clement's Inn* was an Inn of Chancery before the reign of Edward IV., taking its name from the parish church of St. Clement Danes, to which it had formerly belonged.

The *Middle Temple* possesses in its hall one of the most stately and interesting of existing Elizabethan structures. Commenced in 1562, under the auspices of the learned Plowden, then treasurer, it was not completed until 1572, the richly carved screen at the east end in the style of the Renaissance being put up three years later, in 1575. The idea long commonly received that the screen was constructed of timber taken from ships of the Spanish Armada (1588) is therefore baseless. The noble edifice, which through many vicissitudes of fire and popular tumult has been preserved unaltered to the present day, has been the scene of numerous historic incidents, notably the entertainments given within its walls to regal and other personages from Queen Elizabeth downwards. The library, which now contains 28,000 volumes, dates its origin from 1641, when Robert Ashley, a member of the society, bequeathed his collection of books in all classes of literature to the inn, together with a large sum of money; other benefactors were Ashmole (the antiquary), William Petyt (a benefactor of the Inner Temple), and Lord Stowell. From 1711 to 1826 the library was greatly neglected; few works were added either by presentation or purchase, and many of the most scarce and valuable were lost. The present handsome library building, which stands apart from the hall, was completed in 1861, the Prince of Wales attending the inauguration ceremony on October 31st of that year, and becoming a member and bencher of the society on the occasion. The MSS. in the collection are few in number, and of no special value. In civil, canon, and international law, as also in divinity and ecclesiastical history, the library is very rich; it contains also some curious works on witchcraft and demonology. There is but one Inn of Chancery connected with the Middle Temple, that of *New Inn*, which, according to Dugdale, was formed by a society of students previously settled at St. George's Inn, situated near St. Sepulchre's Church without Newgate; but the date of this transfer is not known.

Lincoln's Inn stands on the site partly of an episcopal palace erected in the time of Henry III. by Ralph Nevill, bishop of Chichester and chancellor of England, and partly of a religious house, called Black Friars House, in Holborn. In the reign of Edward II., Henry Lacy, earl of Lincoln, possessed the place, which from him acquired the name of Lincoln's Inn, probably becoming an Inn of Court soon after his death (in 1310), though of its existence as a place of legal study there is little authentic record until the time of Henry VI. (1424), to which date the existing muniments reach back. The fee simple of the inn would appear, however, to have remained vested in the see of Chichester; and it was not until 1580 that the society which for centuries had occupied the inn as tenants acquired the absolute ownership of it. The old hall, built about 1506, still remains (and is temporarily used as one of the courts of the High Court of Justice), but has given place to a modern structure designed by Philip Hardwick, R. A., which, along with the buildings containing the library, was completed in 1845, the Queen attending the inauguration ceremony (October 13). The chapel, built after the designs of Inigo Jones, was consecrated in 1623. The library—as a collection of law books the most complete in the country—owes its foundation to a bequest of John Nethersale, a member of the society, in 1497, and is the oldest of the existing libraries in the metropolis. Various entries in the records of the inn relate to the library, and notably in 1608, when an effort was made to extend the collection, and the first appointment of a master of the library (an office now held in annual rotation by each bencher) was made. The library has been much enriched by donations and by the acquisition by purchase of collections of books on special subjects. It includes also an extensive and valuable series of MSS., the whole comprehending 43,000 volumes. The Inns of Chancery affiliated to Lincoln's Inn are Thavie's Inn and Furnival's Inn. *Thavie's Inn* was a residence of students of the law in the time of Edward III., and is mentioned by Fortescue as having been one of the lesser houses of Lincoln's Inn for some centuries. It thus continued down to 1769, when the inn was sold by the benchers, and thenceforth it ceased to have any character as a place of legal education.

Furnival's Inn become the resort of students about the year 1406, and was purchased by the society of Lincoln's Inn in 1547. In 1817 the inn was rebuilt, but from that date it has ceased to exist as a legal community.

There is no reason to suppose that *Gray's Inn* is of less antiquity than the other Inns of Court. The exact date of its becoming the residence of lawyers is not known, though it was so occupied before the year 1370, and there is abundant evidence of its existence as an Inn of Court after that date. The inn stands upon the site of the manor of Portpoole, belonging in ancient times to the dean and chapter of St. Paul's, but subsequently the property of the noble family of Gray de Wilton and eventually of the crown, from which a grant of the manor or inn was obtained, many years since discharged from any rent or payment. The hall of the inn is of handsome design, similar to the Middle Temple hall in its general character and arrangements, and was completed about the year 1560. The chapel, of much earlier date than the hall, has, notwithstanding its antiquity, but little now to recommend it to notice, being small and insignificant, and lacking architectural features of any kind. The library, including about 13,000 volumes, contains a small but important collection of MSS. and missals, and also some valuable works on divinity. Little is known of the origin or early history of the library, though mention is incidentally made of it in the society's records in the 16th and 17th centuries. The gardens, laid out about 1597, it is believed under the auspices of the lord chancellor Bacon, at that time treasurer of the society, continue to this day as then planned, though with some curtailment owing to the erection of additional buildings in recent years. Among many curious customs maintained in this inn is that of drinking a toast on grand days "to the glorious, pious, and immortal memory of Queen Elizabeth." Of the special circumstances originating this display of loyalty there is no record. The Inns of Chancery connected with Gray's Inn are Staple's and Barnard's Inns. *Staple's Inn* was an Inn of Chancery in the reign of Henry V., and is probably of yet earlier date. Readings and moots were observed here with regularity. Sir Simonds d'Ewes mentions attending a moot in February, 1624. *Barnard's Inn*, anciently designated Mackworth Inn, was an Inn of Chancery in the reign of Henry VI. It was then and still is held of the dean and chapter of Lincoln, to whom a fine of £1400 is payable every fourteen years.

The *King's Inns, Dublin*, the legal school in Ireland, corresponds closely to the English Inns of Court, and is in many respects in unison with them in its regulations with regard to the admission of students into the society, and to the degree of barrister-at-law, as also in the scope of the examinations enforced, though no final examination is now required for call to the bar. Of the twelve terms required to be kept, however, by a student, four must be spent at an Inn of Court in London, admission to which is obtained in the usual manner, but exempt from stamp duty, on the certificate of the under treasurer that such duty has been paid in Ireland. Until lately two years were required to be thus passed in London,—the stipulation dating as far back as 1542 (33 Henry VIII. c. 3). Down to 1866 the course of education pursued at the King's Inns differed from the English Inns of Court in that candidates for admission to the legal profession as attorneys and solicitors carried on their studies with those aspiring to the higher grade of the bar in the same building under a professor specially appointed for this purpose,—herein following the usage anciently prevailing in the Inns of Chancery in London, which, as has already been stated, has long since fallen into desuetude. This arrangement was put an end to by the statute 29 & 30 Vict. c. 84. The origin of the King's Inns may be traced back to the reign of Edward I., when a legal society designated Collett's Inn was established; but, being situated without the walls of the city, the inn was destroyed by an insurrectionary band. In the reign of Edward III. Sir Robert Preston, chief baron of the exchequer, gave up his residence within the city to the legal body, which then took the name of Preston's Inn, where for two centuries the study of the law was pursued and a collegiate discipline maintained. In 1542 the land and buildings known as Preston's Inn were restored to the family of the original donor, and in the same year Henry VIII. granted the monastery of Friars Preachers for the use of the professors of the law in Ireland. In consequence of this grant the legal body removed to the new site, and thenceforward were known by the name of the King's Inns. Possession of this property having been resumed by the Government in the middle of the last century (1742), and the present Four Courts erected thereon, a large space of ground at the top of Henrietta Street was purchased by the society, and the existing hall built in the year 1800. The library, numbering over 50,000 volumes, with a few MSS., is housed in buildings specially provided in the year 1831, and is open, not only to the members of the society, but also to strangers upon proper introduction. The collection is not entirely legal, but comprises all kinds of literature. It is based principally upon a purchase made in 1787 of the large and valuable library of Mr. Justice Robinson, and is maintained chiefly by an annual payment made from the Consolidated Fund to the society in lieu of the right to receive copyright works which was conferred by the Act of 1801 (41 George III. c. 107), but abrogated in 1836 (6 & 7 Will. IV. c. 107). In discipline and professional etiquette the members of the bar in Ireland differ but little from their English brethren. The same style of costume is enforced, the same gradations of rank—attorney-general, solicitor-general, queen's counsel, and ordinary barristers—being found. There are also serjeants-at-law limited, however, to three in number, and designated 1st, 2d, and 3d serjeant; and, unlike their English brethren, these are not as yet in course of extinction. The King's Inns do not provide chambers for business purposes; there is consequently no aggregation of counsel in certain localities, as is the case in London in the Inns of Court and their immediate vicinity.

The corporation known as the *Faculty of Advocates* in Edinburgh corresponds with the Inns of Court in London and the King's Inns in Dublin (see ADVOCATE vol. i. p. 161). The constitution of the faculty differs in many respects, however, from the English and Irish societies. There is no resemblance to the quasi-collegiate discipline and the usages and customs prevailing in an Inn of Court. There is no governing body similar to the benchers. The president is elected by general vote of the whole body of the advocates, and is designated dean of faculty. Until a recent date no precedence excepting that of the lord advocate (who performs many of the duties of the attorney-general in England), the dean of faculty, and the solicitor-general was recognized. Now these officers and the ex-law-officers of the crown obtain patents as queen's counsel. The faculty is possessed of a hall and extensive library buildings situated beneath and adjoining the Parliament House, which have been much added to in the present century. The body regulates all matters connected with admission to its ranks.

Advocates are not required to pass any portion of their studentship in London, as is the case with members of the Irish inn. On the other hand, advocates of the Scottish bar desiring to change the scene of their professional labors to the English metropolis derive no advantage as such (excepting when pleading in appeals at the bar of the House of Lords and in cases before the judicial committee of the privy council), but have to pass through the ordinary curriculum of the English student before acquiring the necessary status; and in like manner an English or Irish barrister seeking admission to the Scottish bar must go through the course prescribed by the faculty.

INOCULATION. See SMALL-POX.

INOWRAZLAW (9147), anciently Jung-Breslau, the chief town of a circle in the government district of Bromberg, is situated on an eminence in the most fertile part of the Prussian province of Posen, 25 miles south-east of the town of Bromberg. It is the seat of a local court, and has several churches, a synagogue, and a gymnasium. Iron-founding, the manufacture of machinery, and an active trade in cattle and country produce are carried on. In the vicinity are important salt works and a sulphur mine, and since 1876 there has been a brine bath establishment within the town. Inowrazlaw is mentioned as early as 1185, and appears several times in the mediæval history of the Teutonic knightly order. The population in 1875, including the garrison and the neighboring Grostnow, was 9147.

INQUEST. See CORONER.

INQUISITION, THE, is the name usually given to that organization which was established in Spain in the 15th century for the detection and suppression of heresy. The "Holy Office," as it was styled, was, however, only the development of a system which, in the hands of the preaching orders, had existed from the beginning of the 13th century; and this in turn did but enforce anew the old view that the church is bound to correct all immorality or misbelief. The subject has therefore three distinct periods:—(1) the treatment of heresy and vice before the 13th century; (2) the Dominican Inquisition, dating from the council of Toulouse in 1229; (3) the Spanish Inquisition, which began in 1480. The second and third periods express a different principle from that which guided the first; for the earlier inquiry into heresy or vice was a part of the episcopal functions, while the second period sprang out of the anti-episcopal and anti-feudal revival of the preaching orders, and the third went with the establishment of a centralized monarchy in Spain, and its claims to a political-religious supremacy in Europe. The first was not directed against any special heresy; the second was called forth by the Albigensian movement, and the literary and artistic independence of southern France; the third expressed the views of Spanish orthodoxy in its struggle with Jew and Moor, and, when that contest was done, it attacked Protestantism, becoming, in union with the Jesuits, the fighting power of the Catholic reaction of the 16th century. The original episcopal Inquisition never forgave its more vigorous and better organized successor; the Spanish Office was nowhere introduced without a struggle, but the Reformation left episcopacy almost powerless in northern Europe, while in the south the renewed and autocratic papacy discouraged the independence of bishops, and trusted itself mainly to the order of Jesus and the Holy Office.

The Inquisition was an outcome of that desire for safety in the truth which distinguishes Christianity from most other forms of faith. If men feel safe, they charitably wish others to be also safe,—hence missionary heroisms; they fear whatever may endanger their safety, and long to clear it away,—hence persecution; they argue that if they make a convert they save a soul, and if not that the stiff unbeliever is too dangerous to be left,—whence come imprisonments and the stake. So long as church and state were distinct, the heretic simply forfeited his privileges as a member of a religious body; but when state and church became, in theory at least, conterminous, this process availed no longer, and the heretic had to be put away by the state, while the church became ever more industrious in seeking out error. Now, in religious matters, men have always tried to make things easier by multiplying difficulties; they secure safety by exact statement and minute definition. Creeds and formularies cease to be symbols of a general consent, and become, instead, tests of orthodoxy. And though, in theory, the church was as anxious for the moral purity as for the right faith of her members, the moral questions were presently eclipsed by the dogmatic; church discipline judged conduct lightly, while it controlled opinion with an iron hand.

1. The germ of the Inquisition lies in the duty of searching out and correcting error entrusted to the deacons in the early churches. The promise in the Anglican Ordinal that the priest will be "ready with all faithful diligence to banish and drive away all erroneous and strange doctrines contrary to God's word" is a pale reflection of this ancient charge. The episcopacy thus providing the instruments, the temporal power soon offered to enforce the sentences of the church: the edicts of Constantine and his successors now began that double system which, by ordaining that heretics should be dealt with διὰ τῆς ἔξωθεν ἐξουσίας, by the secular arm, enabled the church to achieve her object without dipping her own hands in blood. Thus, about 316, Constantine issued an edict condemning the Donatists to lose their goods; and in 382 Theodosius declared the Manichæans guilty of death, and confiscated their goods. Later on, in 769, we learn in the capitularies of Charles the Great that each bishop must visit all his "Parœchia," or diocese, teach truth, correct morals, see that the clergy hold the right faith, and, on the Saxon border, stop the use of any pagan rites. Charles the Bald in 844 orders the bishops to preach and confirm the people, and to inquire into and correct their errors, "ut populi errata *inquirant* et corrigant." In this inquisition, as in other matters, the church long felt the impress of the organizing power of Charles the Great; it helped forward the episcopal dominance in the 9th and 10th centuries. Still, it claimed no special authority, and its action was very partial, and dependent on the temper and energy of each particular bishop. Sometimes it was raised into activity by some bolder movement of independence, as when in Italy in the 11th century the bishops attacked the Patarines, under the impulse of Hildebrand, or as when it was used as an implement for the reduction of the archbishopric of Milan under the papal authority.

2. But when a time of new life came to Europe early in the 13th century, and orthodoxy was threatened by the brilliant speculations of southern France, a great revival in the church met the independent movement outside, and the rise of the Preaching Friars gave a new direction to the relations between religion and the world. Then, as in later days, the "Renaissance shook off many restraints, the good with the bad;" and art went with religious speculation and moral license. The action of the new orders, as a development of the inquisitorial system, was directed almost entirely against opinions, and moral questions were left on one side. To this period we owe the technical use of the terms Inquisitor and Inquisition. Hitherto they had signified, specially in France, officers inquiring into matters of taxation; henceforth they are applied to the more ominous inquiry into orthodoxy. At the council of Tours in 1163, in the time of Alexander III., the title of Inquisitor was first applied in this sense; and, at the council of Toulouse in 1229, the apostolical legate "mandavit *inquisitionem* fieri contra hæreticos suspectos de hæretica pravitate." But the thing was far older than the name. In 1184 the synod of Verona cursed all heretics and their shelterers, ordered relapsed persons to be handed over to the secular arm for capital punishment, confiscated their property, and clearly indicated that the new Inquisition would go far beyond the older episcopal function. The synod did not hesitate to threaten easy-going bishops, urging them to more frequent and more searching visitations, standing over them as a superior power. And henceforward Inquisition becomes more systematized, with papal not episcopal authority; it was developed by

those three masterful pontiffs, Innocent III. (1198–1216), Gregory IX. (1227–1241), and Innocent IV. (1243–1254), who all, regarding the supremacy of Rome as the keystone of society, claimed authority over men's souls and bodies, above the authority of prince or bishop. Thus, soon after his accession, Innocent III. sent two Cistercians, Guy and Regnier, to visit the dioceses of southern France and Spain, "to catch and kill the little foxes," the Waldensians, Cathari, and Patarines, to whose tails were fastened fire-brands to burn up the good corn of the faithful. The bishops and lay authorities were instructed to give all help; a new power, with special papal authorization, had come in, and would interfere with every bishop in his diocese, rouse new activity in the old system, and also act independently as a new engine of inquiry.

Similarly, in 1203, Innocent III. sent Peter of Castelnau and Ralph, two Cistercians of Fontevrault, to preach down the Albigensian heresy; and when persuasion availed little he added to them Arnauld, abbot of Fontevrault, and named the three his apostolical legates, ordering them to deal more sharply with the heretics. The murder of Peter (henceforward styled St. Peter Martyr) in 1209 led to the outbreak of that cruel and disastrous war, the crusade of Simon of Montfort against the Albigensians. But little success attended the effort of these earlier Inquisitors till they were joined by the too famous Castilian Dominic, who, having in 1215 accompanied the bishop of Toulouse to Rome, laid before the pope a scheme for a new order of preaching friars, whose special function should be the overthrow of heresy; Innocent III. approved the order in 1215, and Honorius III. confirmed it in 1216. It spread swiftly through Europe, and the charge of the Inquisition was soon entrusted almost entirely to it. Hitherto there had been no regular tribunal; now, as the war in southern France went on and the strife became more fierce, a stricter organization was introduced. While the strong current of independent opinion was being stemmed in Italy, Provence, France, and Spain, the resistance gave compactness to the new system. St. Dominic established three orders—(1) his friars, (2) a female order, and (3) the "Militia of Christ," an order of laymen, married chiefly and noble, who became the working force of the inquisitorial system; they were also styled "the Familiars of the Holy Office."

It is, however, to Gregory IX. that the Inquisition owes its definite form. In the synod of Toulouse in 1229 it was agreed that each bishop should appoint one priest, and one, two, three, or even more laymen, to inquire, under oath and with much secrecy, into heresy. In 1234 the Dominicans were specially entrusted with the inquisitorial office in Toulouse. From their tribunal there was no appeal to the bishop, who fell into the background, all appeals being directed to Rome alone. To this end Urban IV. appointed, in 1263, an inquisitor-general to be the medium of communication between the papacy and the local inquisitors, in hopes of stopping the delay of business caused by the absence of officials in Rome on appeal questions. This office, however, fell into abeyance till revived by Paul III. in the person of Caraffa in 1542.

From Provence the organization of the Inquisition soon passed into France, where, in 1255, Alexander IV. named the provincial of the Dominicans and the head of the Franciscans at Paris his inquisitors-general for France at the urgent request of Saint Louis, whose piety was of the narrowest crusading type. The Gallican Church stoutly resisted this ultramontane interference; the bishops gave it no help; churches and abbeys became asylums for the victims of the Holy Office; and the new movement had consequently but very partial success. It was more effectively used by Philip the Fair to crush the Templars, though that greedy prince quickly interfered when he found the Inquisition laying hands on his special preserve, the wealthy Jews. Charles V., moved to new efforts by Gregory XI., imprisoned large crowds of Frenchmen for heresy, and to meet the pressure erected several new prisons, among them the ill-omened Bastille. After this the Inquisition was quiet in France till the Reformation once more aroused it in the time of Francis I. In Spain it was introduced by Pope Gregory IX. in 1232, and had a far more active and continuous life; we have a minute account of its system and procedure in the *Directorium Inquisitorum* of N. Eymerich, inquisitor-general for Castile in 1356. This work, based entirely on the writer's personal knowledge and experience, gives us full insight into the way in which cases were got up and handled: we see the spy system, the delation, the mysterious secrecy, the scandal of the "question;" the shameless union in one person of accuser and judge, the unscrupulous hindrances put in the way of the victim's defence, the direct interest of the tribunal in condemning,—for condemnation affirmed vigilance and orthodoxy, while it secured to the Holy Office the wealth of the accused, and the accused were usually among the wealthiest in the land. We can trace the absolute injustice of the institution on every page, and must only wonder that even in those days men could endure its existence. In Italy the Inquisition was established under Dominican supervision as early as 1224; Simone Memmi's famous fresco of the "Domini Canes" in S. Maria Novella at Florence, with its black and white hounds chasing off the wolves from the holy fold, bears living witness to the power of the institution and its influence over the Italian imagination. If Eymerich's book gives us a view of the rules of procedure, the MS. *Liber Sententiarum*, or Book of Judgments, printed in part by Limborch, and containing the acts of the Toulouse Office from 1308 to 1322, gives us a full account of those rules reduced to practice in the earliest tribunal of the reconstructed Office. Between the two we can create for ourselves a complete image of the institution, and judge of its power over the intellects, souls, and bodies of the quick-witted southerners. Inquisitors were at a later time brought into England to combat the Wickliffite opinions.

3. Though it succeeded, with help of the terrible lay-crusade, in southern France, the Inquisition seemed unequal to the problem laid before it in Spain, where, instead of simple-hearted Albigensians, it had to deal with rich and crafty Jews and highly-trained Moors. Forced to profess a Christianity which they hated, they loathed the worship of virgin or saint, the pictured or graven effigy of the Christ, the thousand objects of mediæval worship, all which to their eyes were mere idolatries; their allegiance to such a faith was that of compulsion, which fostered the bitterest sense of wrong. Between them and the old Catholic Spaniards smouldered a perpetual grudge; the Inquisition seemed unable to overcome the evil. When, however, Castile and Aragon were united by Ferdinand and Isabella, political aims as well as religious fanaticism demanded more stringent measures against independent thought; the war of Louis XIV. against freedom of opinion was not more distinctly political than that of the two monarchs, although his machinery was more civil and military than theirs.

Three chief motives led to the reorganization of the Inquisition in Spain:—(1) the suspicions and ill-feeling against the new Christians; (2) the wish of Ferdinand and Isabella to strengthen the compactness of their union, threatened by the separatist tendencies of the wealthy Jews and Moors; and (3) above all, the hope of a rich booty from confiscations, a characteristic which specially marks the history of the Spanish Inquisition. The motive of strictly religious fanaticism influenced, not the monarchs, but the Dominican instruments of the Holy Office. And so when in 1477 Friar Philip de Barberi, inquisitor for Sicily, came to Seville for the confirmation of his office, and pressed on Ferdinand the great advantages of a revived system on the Sicilian plan, the king, led by his hunger for gold, and the queen, guided by her piety, were easily persuaded, and sent to Rome to solicit the establishment of such a tribunal as Barberi suggested. Sixtus IV. in 1478 acceded to their request; his bull for this purpose is, however, lost. But as Isabella wished first to try gentler measures, and as both monarchs were rather alarmed by the independence the proposed tribunal claimed, the papal permission was not made known or acted on till 1480. The monarchs bargained that they should nominate the Inquisitors, hoping thereby to secure a control over the institution; but the real centre of authority was inevitably Rome, and from its outset the Holy Office was ultramontane. Nor indeed is there good ground for Hefele's contention, in which he is followed by the Benedictine Gams of Ratisbon, that the Inquisition was entirely a state institution; the state did take part in it, and tried to draw its own selfish advantages from it, and it was also in name a royal tribunal; but its spirit was completely Dominican, and the impulse of it papal; nor can the church be relieved from the just odium which presses on the memory of the institution.

The first inquisitors named in 1480 were Dominicans; their tribunal was established at Seville, where they were but sullenly received. Early in 1481 they began work, and before that year was out had burnt 298 victims in Seville alone, besides many effigies of those who had happily escaped. The Jesuit historian Mariana assures us that in this year full 2000 were burnt in the archbishopric of Seville and the bishopric of Cadiz; the Quemadero, or cremation-place, built at this time by the prefect of Seville, not far from that city, a square platform of stone, was a grim altar on which the lives of almost daily victims ascended in clouds of smoke to heaven. This new blessing, however, was but unwillingly welcomed by the Spaniards; the capital of Castile remembered its ancient learning and splendor, and the wealth and intelligence of its old Moorish inhabitants; complaints and protests poured in on Sixtus IV., especially from the bishops; and in 1483, in one of his briefs the pope actually ordered a softening of the rigors of the Holy Office; he also named the archbishop of Seville, D. Inigo Manriquez, his sole judge of appeals in matters of faith, hoping thereby to still the strong jealousy of the episcopate. He was also somewhat offended because Ferdinand and Isabella held back the papal share of the spoils.

Shortly afterwards, October, 1483, the Dominican father Thomas of Torquemada (de Turrecremata) was named by Sixtus IV. inquisitor-general for Castile and Leon. From him the institution received its full organization. He became its president; by his side were two lawyers as assessors, and three royal counsellors. This scheme was not large enough for the work; it was shortly amended, and there was now a central court styled the Consejo de la Suprema, composed of the grand inquisitor-general, six apostolical counsellors, a fiscal procurator, three secretaries, an alguazil (or head policeman) a treasurer, four servants of the tribunal, two reporters or informers, and as many consultors as might be needful. Under this central tribunal four local tribunals were also appointed. All the officials were well paid from the confiscation-fund; it was the interest of all that that stream of wealth should never run dry; Torquemada was to the full as eager as Ferdinand for profit from this unholy source: the chief spoils of the institution fell to the crown; the true accession of strength was at Rome.

This royal council of the Inquisition, as it was now styled, proceeded next to draw up its rules. Torquemada in 1484 summoned to Seville all heads of local tribunals, who presently published a code of thirty-nine articles. The dreary list regulates the procedure of the Holy Office. The articles were originally twenty-eight; of these 1 to 10 deal with the summons to heretics to come forward and confess, and with the penalties to the submissive; 11 to 13 with penitence in the prisons of the Office; 14 to 19 treat of the procedure of trial, including torture; 20 and 21 extend the jurisdiction of the tribunal to dead heretics and the vassals of living nobles; the remainder are on points of detail in the management. Afterwards eleven more rules were added, on points of less interest: they deal with the organization of the smaller tribunals, guard against bribery of officials, establish an agent at Rome, and make fresh and minute directions as to confiscations and the payment of inquisitors' salaries; the money question comes up perpetually. In no part of Spain was the system well received; the resistance in Aragon passed into revolt and assassination, which were only overcome by the united efforts of the Dominicans, the papacy, and the sovereign, aided to some extent by the "Old Christians" (*i. e.*, those not of Jewish origin), whose jealousy towards the new Christians and the Moors led them to favor a system which repressed their rivals.

The Holy Office had now free scope for its work, and its procedure, arranged by Torquemada, will explain how thoroughly it succeeded in terrifying all who came within its reach. When an accused or suspected person was first delated to the Inquisition, a preliminary inquiry was held, and the results of it laid before the tribunal. If the tribunal thought it a case for interference, and it usually did so, the informers and witness were re-examined, and their evidence, with all suspicious circumstances which zeal could rake together, drawn out and submitted to a body of monastic theologians called "the Qualifiers of the Holy Office." The character of these officials was at stake, and their honor involved; they could hardly be expected to report well of the accused, or there might be a suspicion as to their own orthodoxy. When they had given in their opinion against the accused, he was at once removed to the secret prison of the Office, where all communication with the outer world was entirely cut off from him. Then followed three "first audiences," in which the officials did their utmost to wring a confession out of him, so that he might be made to rank as a penitent, and enjoy the charity of his persecutors. If, however, he was stiff, the charges against him were re-formed, and the fiscal in charge of the case demanded torture to extort confession. This in the earlier times of the institution followed frequently, and had many forms of ingenious cruelty, as to which Llorente, who had good means of judging, declares that "none of the descriptions of them can be accused of exaggeration." After torture, the shattered victim was carried to the audience chamber, and called on to make his answer to the charges, which were now read to him for the first time. He was next asked whether he desired to make any defence. If so, he had to choose a lawyer from a list of those employed by his accusers, and the defence was little but a mockery. After this process, which sometimes lasted for months, the qualifiers were again called in, and gave their final opinion, which was almost always adverse, on the whole case. Then followed the sentence, with opportunity of an appeal either to the "Suprema"—which was useless, as being an appeal to the tribunal again—or to Rome. The papal treasury by these appeals obtained a large income; for money was the only valid argument. Thus the Inquisition got the victim's property by confiscation, and the papacy the wealth of his friends in the appeal. If the sentence was, as did sometimes occur, an acquittal, the poor wretch might slink home without redress or recompense for imprisonment, and the agony of the trial and the torture; if it was a condemnation, the victim was made the centre of an *auto-da-fé*, dressed in a sanbenito, or condemned man's robe, and eventually, at the open place of execution, informed as to his fate. He might be either "reconciled," and then, as a penitent, had to undergo penalties almost worse than death, or "relaxed," that is, handed over to the secular arm for burning,—for the Holy Office shed no blood.

This then was the instrument by which the purity of Christendom was to be assisted and defended, "misericordia et justitia," as the motto of the institution runs, by the most flagrant injustice, and by the infliction of those cruel "tender mercies" of which the Book of Proverbs speaks.

In 1492 the great work began with the persecution and expulsion of the Jews; they were ejected, and their wealth confiscated. There was an enormous crowd of exiles, who wandered to different shores of the Mediterranean, carrying misery and plague in their train. A few years later, under supervision of Cardinal Ximenes, the Moors were also ordered to be converted or to go; the Morescoes, or Christianized Moors, suffered constant persecution throughout the 16th century, until finally they too were expelled by Philip III. in 1609. Jews, Moors, and Morescoes made up over three millions of the wealthiest and most intelligent inhabitants of Spain; the loss in trade, agriculture, and manufactures was incalculable; in seventy years the population fell from ten to six millions.

Ximenes was the greatest organizer, after Torquemada, of the Office; he divided the whole Inquisition into ten tribunals,—Seville as the capital, Jaen, Toledo, Estremadura, Murcia, Valladolid, Majorca, Pampeluna, Sardinia, and Sicily; and, though the bishops still resisted his authority, he carried his will through with a high hand. The Inquisition was set up in all the colonies and dependencies of Spain; it established itself as a theological quarantine at all the harbors, and greatly checked the development of Spanish trade. The horror of the English at the institution was much due to the collision of the English traders and adventurers of Queen Elizabeth's day with the Inquisition on the Spanish main, and to its interference with that freedom of traffic which they desired. The new Inquisition was set up in the Netherlands by Charles V. in 1522; it was exceedingly severe, and greatly hated by the people (see HOLLAND) under Philip II. and Alva. In Portugal the Holy Office established itself in its sharpest form, and continued there in full force even when the Jesuits were suppressed. It was introduced into France under Henry II. (1557), though its hold on that country was small. In Italy it had free course during the 16th century and vigorously supported the Catholic reaction, especially when the very soul of the Inquisition, Michele Ghislieri, had ascended the pontifical throne as Pius V. Its organization was also strengthened by Sixtus V., who secured it at Rome.

The hand of the Holy Office was outstretched against all; no lofty dignity in church or state, no eminence in art or science, no purity of life, could defend from its attacks. It is said to have threatened Charles V. and Philip II.; it persecuted Archbishop Carranza, head of the church in Spain; destroyed De Dominis, archbishop of Spalatro; it smote Galileo, murdered Giordano Bruno, attacked Pico di Mirandola, and even is said to have threatened Cæsar Borgia. With equal vigor, in combination with the Jesuits, the Inquisition made war on books and learning, religious or secular alike; we have seen how baleful was its effect in earlier days on literature and art in Provence, and in the time of the Catholic sovereigns on the material well-being of Spain. "In the love of Christ and his maid-mother," says Queen Isabella, "I have caused great misery, and have depopulated towns and districts, provinces and kingdoms."

The statistics of death at the hands of the Inquisition in Spain given by Llorente show how the institution gradually lost force; the average number in each year steadily diminished after the beginning of the 17th century; and in the 18th torture was abandoned, and the deaths dropped to two or three or even less in the year. In Italy it was abolished in Parma and Tuscany about 1769, in Sicily in 1782; the spirit of the 18th century was all against the Office, though it lingered on. In the Revolution wars Napoleon sternly crushed it wherever he came across it, in Spain in 1808, and in Rome in 1809. Down to 1809 Llorente gives as the figures for Spain alone—burnt alive 31,912, in effigy, 17,659, and imprisoned, etc., as penitents, 291,450—a total of 341,021. After the hand of Napoleon was taken off, the institution revived again at Rome and at Madrid; but its teeth were gone; and it could do little but show a murderous will. The last capital punishments were those of a Jew who was burnt, and a Quaker school-master hanged, in Spain in 1826. Still, its voice is sometimes heard; in 1856 Pius IX. issued an encyclical against somnambulism and clairvoyance, calling on all bishops to inquire into and suppress the scandal, and in 1865 he uttered an anathema against freemasons, the secular foes of the Inquisition.

The occupation of Rome in 1870 (see ITALY) drove the papacy and the Inquisition into the Vatican, and there at last John Bunyan's vision seems to have found fulfilment. Yet, though powerless, the institution is not hopeless; the Catholic writers on the subject, after long silence or uneasy apology, now acknowledge the facts, and seek to justify them. In the early times of the Holy Office its friends gave it high honor; Paramo, the inquisitor, declares that it began with Adam and Eve ere they left Paradise; Paul IV. announced that the Spanish Inquisition was founded by the inspiration of the Holy Spirit; Muzarelli calls it "an indispensable substitute to the church for the original gift of miracles exercised by the apostles." And now again, from 1875 to this day, a crowd of defenders has risen up: Father Wieser and the Innsbruck Jesuits in their journal (1877) yearn for its re-establishment; Orti y Lara in Spain, the Benedictine Gams in Germany, and C. Poullet in Belgium take the same tone; it is a remarkable phenomenon, due partly to despair at the progress of society, partly to the fanaticism of the late pope, Pius IX. It is hardly credible that any one can really hope and expect to see in the future the irresponsible judgments of clerical intolerance again humbly carried out, even to the death, by the secular arm.

In the mass of literature on the subject, the most important works are—N. Eymerich, *Directorium Inquisitorum*, Rome, 1587; F. Valdes, *Edict establishing Procedure, etc.*. Madrid, 1561; L. de Paramo (a Sicilian inquisitor), *De origine et progressu Officii Sanctæ Inquisitionis, ejusque dignitate et utilitate*, Madrid, 1598; Philip van Limborch, *Historia Inquisitionis, cui subjungitur Liber Sententiarum inquisitionis Tholosanæ*, Amsterdam, 1692; and the Abbé Marsollier's *Histoire de l'Inquisition et de son Origine*, Cologne, 1693, a work based on Limborch; J. A. Llorente, *Historia critica de la inquisicion de España*, Madrid, 1812, 1813; Gams, *Kirchengeschichte von Spanien*, vol. iii. pt. 2, Ratisbon, 1876; F. Hoffman, *Geschichte der Inquisition*, 2 vols., Bonn, 1878; Molinier, *L'Inquisition dans le midi de la France au treizième et au quatorzième Siècle*, 1880. The modern defenders of the Inquisition are F. J. G. Rodrigo, *Historia verdadera de la Inquisicion*, 3 vols., Madrid, 1876, 1877; and J. M. Orti y Lara, *La Inquisicion*, Madrid, 1877. (G. W. K.)

INSANITY.

INSANITY is a generic term applied to certain morbid mental conditions produced by defect or disease of the brain. The synonyms in more or less frequent use are mental disease, alienation, derangement or aberration, madness, unsoundness of mind. There are many diseases of the general system productive of disturbance of the mental faculties which, either on account of their transient nature, from their being asso-

OF RELIGION

ciated with the course of a particular disease, or from their slight intensity, are not included under the head of insanity proper. From a strictly scientific point of view it cannot be doubted that the fever patient in his delirium, or the drunkard in his excitement or stupor, is insane—that, the brain of either being under the influence of a morbific agent or of a poison, the mental faculties are deranged; yet such derangements are regarded as functional disturbances, *i. e.*, disturbances produced by agencies which experience tells will, in the majority of cases, pass off within a given period without permanent results on the tissues of the organ. The comprehensive scientific view of the position is that all diseases of the nervous system, whether primary or secondary, congenital or acquired, should, in the words of Griesinger, be regarded as one inseparable whole, of which the so-called mental diseases comprise only a moderate proportion. However important it may be for the physician to keep this principle before him, it may be freely admitted that it cannot be carried out fully in practice, and that social considerations compel the medical profession and the public at large to draw an arbitrary line between such functional diseases of the nervous system as hysteria, hypochondriasis, and delirium on the one hand, and such conditions as mania, melancholia, and dementia on the other.

All attempts at a short definition of the term insanity have proved unsatisfactory; perhaps the nearest approach to accuracy is attained by the rough statement that it is *a chronic disease of the brain inducing chronic disordered mental symptoms*—the term disease being used in its widest acceptation. But even this definition is at once too comprehensive, as under it might be included certain of the functional disturbances alluded to, and too exclusive, as it does not comprehend certain rare transitory forms. Still, taken over all, this may be accepted as the least defective short definition; and moreover it possesses the great practical advantage of keeping before the student the primary fact that insanity is the result of disease of the brain, that it is not a mere immaterial disorder of the intellect. In the earliest epochs of medicine the corporeal character of insanity was generally admitted, and it was not until the superstitious ignorance of the Middle Ages had obliterated the scientific, though by no means always accurate, deductions of the early writers that any theory of its purely psychical character arose. At the present day it is unnecessary to combat such a theory, as it is universally accepted that the brain is the organ through which mental phenomena are manifested, and therefore that it is impossible to conceive of the existence of an insane mind in a healthy brain. On this basis insanity may be defined as consisting in *morbid conditions of the brain, the results of defective formation or altered nutrition of its substance induced by local or general morbid processes, and characterized especially by non-development, obliteration, impairment, or perversion of one or more of its psychical functions.* Thus insanity is not a simple condition; it comprises a large number of diseased states of the brain, which have been gathered under one popular term on account of mental defect or aberration being the predominant symptom.

The insanities are sharply divided into two great classes—the Congenital and the Acquired. Under the head of Congenital Insanity fall to be considered all cases in which, from whatever cause, brain development has been arrested, with consequent impotentiality of development of the mental faculties; under that of Acquired Insanity all those in which the brain has been born healthy, but has suffered from morbid processes affecting it primarily, or from diseased states of the general system implicating it secondarily. In studying the causation of these two great classes, it will be found that certain remote influences exist which are believed to be commonly predisposing; these will be considered as such, leaving the proximate or exciting causes until each class with its genera comes under review.

In most treatises on the subject will be found discussed the bearing which civilization, nationality, occupation, education, etc., have, or are supposed to have, on the production of insanity. Such discussions are generally eminently unsatisfactory, founded as they are on common observation, broad generalizations, and very imperfect statistics. As they are for the most part negative in result, at the best almost entirely irrelevant to the present purpose, it is proposed merely to shortly summarize the general outcome of what has been arrived at by those authorities who have sought to assess the value to be attached to the influence exercised by such factors, without entering in any detail on the theories involved. (1) *Civilization.*—Although insanity is by no means unknown amongst savage races, there can be no reasonable doubt that it is much more frequently developed in civilized communities; also that, as the former come under the influence of civilization, the percentage of lunacy is increased. This is in consonance with the observation of disease of whatever nature, and is dependent in the case of insanity on the wear and tear of nerve tissue involved in the struggle for existence, the physically depressing effects of pauperism, and on the abuse of alcoholic stimulants; each of which morbid factors falls to be considered separately as a proximate cause. (2) *Nationality.*—In the face of the imperfect social statistics afforded by most European and American nations, and in their total absence or inaccessibility amongst the rest of mankind, it is impossible to adduce any trustworthy statement under this head. (3) *Occupation.*—There is nothing to prove that insanity is in any way connected with the prosecution of any trade or profession *per se.* Even if statistics existed (which they do not) showing the proportion of lunatics belonging to different occupations to the 1000 of the population, it is obvious that no accurate deduction *quoad* the influence of occupation could be drawn. (4) *Education.*—There is no evidence to show that education has any influence over either the production or the prevention of insanity. The general result of discussions on the above subjects has been the production of a series of arithmetical statements, which have either a misleading bearing or no bearing at all on the question. In the study of insanity statistics are of slight value from the scientific point of view, and are only valuable in its financial aspects.

Of much greater importance is the question of hereditary predisposition to nervous disease. There is a general and warrantable position taken up by the medical profession, founded on the observation of ages, that a constitutional condition may be generated in a family, which, although it may never manifest itself in a concrete form of disease, may materially influence development, or may make itself felt in a more subtle manner by a mere tendency to degenerative changes. In this wise hereditary predisposition may be regarded as a common factor in all insanities—in the congenital class as an arrester of brain development, in the acquired as the producer of the nervous diathesis. How the constitutional condition is generated, and in what its pathological nature consists, is beyond the ken of science; it may in fact be freely admitted that the proof of its existence hangs more on popular observation than on scientific evidence. The observation is not confined to the nervous system; it extends itself to others, as is shown by hereditary predisposition to gout, consumption, cancer, and other diseases.

It has been strongly asserted that consanguineous marriage is a prolific source of nervous instability. There is considerable diversity of opinion on this subject; the general outcome of the investigations of many careful inquirers appears to be that the offspring of healthy cousins of a healthy stock is not more liable to nervous disease than that of unrelated parents, but that where there is a family history of diathesis of any kind there is a strong tendency in the children of cousins to degeneration, not only in the direction of the original diathesis, but also towards instability of the nervous system.[1] The objection to the marriage of blood relations does not rise from the bare fact of their relationship, but has its ground in the fear of their having similar vitiations in their constitution, which, in their children, are prone to become intensified. There is sufficient evidence adducible to prove that close breeding is productive of degeneration; and when the multiform functions of the nervous system are taken into account, it may almost be assumed not only that it suffers concomitantly with other organs, but that it may also be the first to suffer independently.

Of the other causes affecting the parents which appear to have an influence in engendering a predisposition to insanity in the offspring, the abuse of alcoholic stimulants and opiates, over-exertion of the mental faculties, advanced age, and weak health may be cited. Great stress has been laid on the influence exercised by the first of these conditions, and many extreme statements have been made regarding it. Such must be accepted with reserve, for, although there is reason for attaching considerable weight to the history of ancestral intemperance as a probable causating influence, it has been generally assumed as the proved cause by those who have treated of the subject, without reference to other agencies which may have acted in common with it, or quite independently of it. The question has not as yet been fairly worked out. However unsatisfactory from a scientific point of view it may appear, the general statement must stand—that whatever tends to lower the nervous energy of a parent may modify the development of the progeny. It is merely a matter of probabilities in a given case.

Constitutional tendency to nervous instability once established in a family may make itself felt in various directions,—epilepsy, hysteria, hypochondriasis, neuralgia, certain forms of paralysis, insanity, eccentricity. It is asserted that exceptional genius in an individual member is a phenomenal indication.

Confined to the question of insanity, this morbid inheritance may manifest itself in two directions,—in defective brain organization manifest from birth, or from the age at which its faculties are potential, *i. e.*, congenital insanity; or in the neurotic diathesis, which may be present in a brain to all appearance congenitally perfect, and may present itself merely by a tendency to break down under circumstances which would not affect a person of originally healthy constitution.

In systematic works and in asylum reports, it has been too much the fashion to accept the evidence of the existence of insanity in a relative as a proof of hereditary predisposition in a given case. In estimating the value to be attached to such histories, two things must be taken into acccount,—first, the amount and quality of proved ancestral nervous disease, and, secondly, the period of life at which it appeared in the alleged insane ancestor. Take, for instance, the case of a lunatic whose father or mother is reported to have died insane; this may be true in fact, but may still have no bearing on the causation of the patient's insanity; for the parent may have been the subject of mental disease at a period subsequent to the birth of the child, he may have drunk himself into alcoholic mania late in life, or disease of the cerebral arteries in old age may have produced senile insanity. It is difficult to limit the remoteness of relationship in tracing hereditary predisposition, mainly from the fact that it frequently skips a generation. As a rule it does not confine itself to a single individual of a family, but makes itself felt in one form or another in several members. According to Esquirol and Baillarger, it is more frequently transmitted through the female than through the male branch, but this opinion is called in question by Koch of Würtemberg, whose statistics show that hereditary tendency to insanity acts more strongly through the father than through the mother.

CONGENITAL INSANITY.

The morbid mental conditions which fall to be considered under this head are *Idiocy* (with its modification *Imbecility*) and *Cretinism.*

Idiocy.—In treating of idiocy it must be carefully borne in mind that we are dealing with mental phenomena disassociated from active bodily disease, and that, in whatever degree it may exist, we have to deal with a brain condition fixed by the pathological circumstances under which its possessor came into the world, or by such as had been present before full cerebral activity could be developed, and the symptoms of which are not dependent on the intervention of any subsequent morbid process. From the earliest ages the term *Amentia* has been applied to this condition, in contradistinction to *Dementia*, the mental weakness following on acquired insanity.

The causes of congenital idiocy may be divided into four classes:—(1) hereditary predisposition, (2) constitutional conditions of one or both parents affecting the constitution of the infant, (3) injuries of the infant head prior to or at birth, and (4) injuries or diseases affecting the infant head during infancy. All these classes of causes may act in two directions: they may produce either non-development or abnormal development of the cranial bones, as evidenced by microcephalism or by deformity of the head; or they may induce a more subtle morbid condition of the constituent elements of the brain. As a rule, the pathological process is more easily traceable in the case of the last three classes than in the first. For instance, in the case of constitutional conditions of the parents we may have a history of syphilis, a disease which often leaves its traces on the bones of the skull; and in the third case congenital malformation of the brain may be produced by mechanical causes acting on the child in utero, such as attempts to procure abortion, and deformities of the maternal pelvis rendering labor difficult and instrumental interference necessary. In such cases the bones of the skull may be injured; it is only fair, however, to say that more brains are saved than injured by instrumental interference. With regard to the fourth class, it is evident that the term congenital is not strictly applicable; but, as the period of life implicated is that prior to the potentiality of the manifestation of the intellectual powers, and as the result is identical with that of the other classes of causes, it is warrantable to connect it with them, on pathological principles more than as a mere matter of convenience.

Dr. Ireland, in his work *On Idiocy and Imbecility*, classifies idiots from the standpoint of pathology as follows:—(1) Genetous idiocy: in this form, which he holds to be complete before birth, he believes the presumption of heredity to be stronger than in other forms; the vitality of the general system is stated to be lower than normal; the palate is vaulted and narrow, the teeth misshapen, wrongly placed, and prone to decay, and the patient dwarfish in appearance; the head is generally unsymmetrical and the commissures occasionally atrophied; (2) Microcephalic idiocy, a term which explains itself; (3) Eclampsic idiocy, due to the effects of infantile convulsions; (4) Epileptic idiocy; (5) Hydrocephalic idiocy, due to water on the brain; (6) Paralytic idiocy, a rare form, due to the brain injury causing the paralysis; (7) Traumatic idiocy, a form produced by the third class of causes above mentioned; (8) Inflammatory idiocy; (9) Idiocy by deprivation of one or more of the special senses. Dr. Ireland's wide experience has enabled him to differentiate these groups further by describing the general characteristics, mental and physical, of each.

---

[1] See Report of Committee appointed by New York State Medical Society, in *American Journal of Insanity*, 1870; G. H. Darwin, *Statistical Society's Journal*, June, 1875; Dr. Langdon Down, "On Marriages of Consanguinity," *London Hospital Clinical Lectures and Reports*, 1866; Dr. Arthur Mitchell, "On Consanguineous Marriages," in *Edin. Med. Journ.*, 1865; Maudsley, "On Hereditary Tendency," *Journal of Mental Science*, Jan., 1863, and Jan., 1864; Trousseau, *Clinique Médicale de l'Hôtel de Dieu de Paris*, 1868, vol. ii. pp. 129–137; Alfred Henry Huth, *The Marriage of Near Kin*, 1875.

The general conformation of the idiot is often very imperfect; he is sometimes deformed, but more frequently the frame is merely awkwardly put together and he is generally of short stature. Only about one-fourth of all idiots have heads smaller than common. Many cases are on record in which the cranial measurements exceed the average. It is the irregularity of development of the bones of the skull, especially at the base, which marks the condition. Cases, however, often present themselves in which the skull is perfect in form and size. In such the mischief has begun in the brain matter. The palate is very often highly arched, in some cleft; hare-lip is not uncommon; in fact congenital defect or malformation of other organs than the brain is more commonly met with amongst idiots than in the general community. Of the special senses, hearing is most frequently absent. Sight is good, although co-ordination may be defective. Many are mute. On account of the mental dulness it is difficult to determine whether the senses of touch, taste, and smell suffer impairment; but the impression is that their acuteness is below the average. It is needless to attempt a description of the mental phenomena of idiots, which range between utter want of intelligence and mere weakness of intellect.

The term Imbecility has been conventionally employed to indicate the less profound degrees of idiocy, but in point of fact no distinct line of demarcation can be drawn; the application of either term to a given case depends more on the opinion of the observer than on the condition of the observed. As the scale of imbeciles ascends it is found that the condition is evidenced not so much by low obtuseness as by irregularity of intellectual development. This serves to mark the difference between the extreme stupidity of the lowest of the healthy and the highest form of the morbidly deprived type. The two conditions do not merge gradually one into the other. Extreme stupidity and sottishness mark many cases of idiocy, but only in the lowest types, where no dubiety of opinion can exist as to their nature, and in a manner which can never be mistaken for the dulness of the man who is less talented than the average of mankind. Where in theory the morbid (morbid in the sense of deprivation) and the healthy types might be supposed to approach each other, in practice we find that, in fact, no debatable ground exists. The uniformity of dulness of the former stands in marked opposition to the irregularity of mental conformation in the latter. Comparatively speaking, there are few idiots or imbeciles who are uniformly deprived of mental power; some may be utterly sottish, living a mere vegetable existence, but every one must at least have heard of the quaint and crafty sayings of manifest idiots indicating the presence of no mean power of applied observation. In institutions for the treatment of idiots and imbeciles, children are found not only able to read and write, but even capable of applying the simpler rules of arithmetic. A man may possess a very considerable meed of receptive faculty and yet be idiotic in respect of the power of application; he may be physically disabled from relation, and so be manifestly a deprived person, unfit to take a position in the world on the same platform as his fellows.

Dr. Ireland subdivides idiots, for the purposes of education, into five grades,—the first comprising those who can neither speak nor understand speech, the second those who can understand a few easy words, the third those who can speak and can be taught to work, the fourth those who can be taught to read and write, and the fifth those who can read books for themselves. The treatment of idiocy and imbecility consists almost entirely of attention to hygiene, and the building up of the enfeebled constitution, along with endeavors to develop what small amount of faculty exists by patiently applied educational influences. The success which has attended this line of treatment in many of our public and private institutions has been very considerable. It may be safely stated that all idiotic or imbecile children have a far better chance of amelioration in asylums devoted to them than by any amount of care and teaching lavished upon them at home.

In the class of idiots just spoken of imperfect development of the intellectual faculties is the prominent feature,—so prominent that it masks the arrest of potentiality of development of the moral sense, the absence of which, even if noticed, is regarded as relatively unimportant; but, in conducting the practical study of congenital idiots, a class presents itself in which the moral sense is wanting or deficient, whilst the intellectual powers are apparently up to the average. It is the custom of writers on the subject to speak of "intellectual" and "moral" idiots. The terms are convenient for clinical purposes, but the two conditions cannot be disassociated, and the terms therefore severally only imply a specially marked deprivation of intellect or moral sense in a given case. The everyday observer has no difficulty in recognizing as a fact that deficiency in receptive capacity is evidence of imperfect cerebral development; but it is not so patent to him that the perception of right and wrong can be compromised through the same cause, or to comprehend that loss of moral sense may result from disease. The same difficulty does not present itself to the pathologist; for, in the case of a child born under circumstances adverse to brain development, and in whom no process of education can develop an appreciation of what is right or wrong, although the intellectual faculties appear to be but slightly blunted or not blunted at all, he cannot avoid connecting the psychical peculiarity with the pathological evidence. The world is apt enough to refer any fault in intellectual development, manifested by imperfect receptivity, to a definite physical cause, and is willing to base opinion on comparatively slight data; but it is not so ready to accept the theory of a pathological implication of the intellectual attributes concerned in the perception of the difference between right and wrong. Were, however, two cases pitted one against another—the first, one of so-called intellectual, the second, one of so-called moral idiocy—it would be found that, except as regards the psychical manifestations, the cases might be identical. In both there might be a family history of tendency to degeneration of the nervous system, a peculiar cranial conformation, a history of nervous symptoms during infancy, and of a series of indications of mental incapacities during adolescence, differing only in this, that in the first the prominent indication of mental weakness was inability to add two and two together, in the second the prominent feature was incapacity to distinguish right from wrong. What complicates the question of moral idiocy is, that many of its subjects can, when an abstract proposition is placed before them, answer according to the dictates of morality, which they may have learnt by memory. If asked whether it is right or wrong to lie or steal they will say it is wrong; still, when they themselves are detected in either offence, there is an evident non-recognition of its concrete nature. The question of moral idiocy will always be a moot one between the casuist and the pathologist; but, when the whole natural history of such cases is compared, there are points of differentiation between them and mere moral depravity which must appeal to even biased observers. Family history, individual peculiarities, the manifest imbecility of the acts committed, the general bizarre nature of the phenomena, remove such cases from the ordinary category of crime.

Statistics.—According to the census returns of 1871 the total number of persons described as Idiots and Imbeciles in England and Wales was 29,452, the equality of the sexes being remarkable—namely, 14,728 males and 14,724 females. Compared with the entire population, the ratio is one idiot or imbecile to 771 persons, or 13 per 10,000 persons living. Whether the returns are defective, owing to the natural sensitiveness of persons who would desire to conceal the occurrence of idiocy in their families, we have no means of knowing; but such a feeling is no doubt likely to exist among those who look upon mental infirmity as humiliating, rather than as one of the many physical evils which afflict humanity. According to Ireland, this number (29,452) is 25 per cent. below the mark. The following table shows the number of idiots according to official returns of the various countries; probably they are subject to the same criticism as the census return for England.

	Males.	Females.	Total.	Proportion to 100,000 of population.
England and Wales..........	14,728	14,724	29,452	130
Scotland	2,304	2,317	4,621	134
Ireland....	...	...	8,151	150
France (including Cretins)..	20,456	14,677	35,133	97
Germany (1871).................	16,133	14,395	33,739	82
Sweden (1870)....................	...	...	1,632	38
Norway.........	...	...	2,039	116
United States (1870).........	13,219	9,209	22,428	58

The relative frequency of congenital and acquired insanity in various countries is shown in the following table, taken from Koch's statistics of insanity in Würtemberg, which gives the number of idiots to 100 lunatics:—

Prussia	158	France	66
Bavaria	154	Denmark	58
Saxony.........................	162	Sweden	22
Austria	53	Norway	65
Hungary......................	140	England and Wales......	74
Canton of Bern............	117	Scotland	68
America	79	Ireland	69

It is difficult to understand the wide divergence of these figures, except it be that in certain states, such as Prussia and Bavaria, dements have been taken along with aments, and in others cretins. This cannot, however, apply to the case of France, which is stated to have only 66 idiots to every 100 lunatics. In many districts of France cretinism is very common; it is practically unknown in England, where the proportion of idiots is stated as higher than in France; and it is rare in Prussia, which stands at 158 idiots to 100 lunatics. Manifestly imperfect as this table is, it shows how important an element idiocy is in social statistics; few are aware that the number of idiots and that of lunatics approach so nearly.

Cretinism.—Crétin probably comes from *Chrétien*, either from the idea that the person was innocent in the sense in which that word is employed occasionally to imply a person who cannot sin, or from the religious respect in which cretins were held. Cretinism is a form of congenital insanity inasmuch as the cretinogenetic miasma acts before birth; it is endemic in many mountainous countries, and is said to occur most frequently on magnesian limestone formations, but never at an elevation above 3000 feet. Although all cretins have not goitre, and all goitrous persons are not cretins, there is a very intimate relationship between the two conditions. The districts in Europe in which it is most common are the departments of Hautes-Pyrénées, Haute-Savoie, and Hautes-Alpes; Styria, Upper Austria, the province of Aosta, and Sardinia. It is found more sparsely in other parts of Europe, and also among the Himalayas and Andes. It occasionally presents itself in flat countries,—a remarkable instance being the island of Niederwerth below Coblentz, where out of 750 inhabitants there are 131 cretins (Dr. Ireland). Notwithstanding the circumscribed area in which this disease exists, affording, it might be supposed, data founded on the conditions of life common to their inhabitants for arriving at conclusions as to its cause, nothing has been definitely determined. Cretinism has occupied the attention of many eminent observers, but the various theories they have advanced have been in succession overturned. It has been suggested that the condition is due to the constant use of snow water, or to the presence of sulphate of iron or of lime in water, but none of these theories admit of universal application. That the disease is due to some geological or climatic cause appears certain from the fact, stated by Baillarger, that it disappears from a family in one or two generations after removal to a healthy climate, and may even be prevented by the gravid mother leaving a valley where it is rife for localities where cretinism is unknown. The physical and mental symptoms of cretinism are so closely allied in essentials to those of congenital idiocy as not to demand a separate description. The marked features of the disease are its endemic nature and its intimate connection with goitre. See CRETINISM.

Acquired Insanity.

Pathology.

It is predicated in treating of Acquired Insanity that we have to deal with brains congenitally perfect, the exercise of whose functions has been normal until the incidence of disease. A full description of the tissues of the healthy brain will be found in the article ANATOMY (vol. i. pp. 763–773), a careful perusal of which will very materially assist the reader in following the present remarks on pathology. A short recapitulation of certain anatomical facts is, however, necessary. The purely nervous structures of the brain consist of very delicate fibres and cells, the latter occurring only in the gray matter. It is richly supplied with blood vessels, the supply being six times greater to the gray matter than to the white. These tissues are supported and separated one from the other by a connective tissue, or interstitial matter, the *neuroglia;* the whole organ is enveloped in membranes which separate it from the skull. By one system of independent fibres (the expansion system) communication is maintained between the spinal cord, the central ganglia, and the cortical gray matter; by a second system of fibres (the commissural), corresponding and identical regions of the gray matter of the two opposite hemispheres are united; and by a third system (the horizontal) communication is maintained between parts of the same hemisphere. The cells communicate one with the other by means of processes or poles, fine projections from the body of the cell. The observations of Cleland and Boll show that the apical processes become connected with the fibres as they go to the periphery; the basal processes loop with the horizontal fibres, and also, by means of their recurrent poles, with those of the expansion series. But it is of great importance to observe that we have no evidence of fibre communicating directly with fibre, or no certain proof that one series of fibres communicates directly with others; in fact, all anatomical demonstration goes to prove the individuality and isolation of fibre, the processes of the cells being the connecting link. It is universally accepted that the cerebral cells possess the vital property of generating, receiving, and transmitting nervous influences, and that the fibres are the organs by means of which these influences are received and communicated. In the words of Herman, "in a part of the central organs (the cortical cells) certain material processes are accompanied in an inexplicable manner with wholly undefinable phenomena which characterize what we term *consciousness.*" The term *mind* may be applied to the combination of all the actual and possible states of consciousness of the organism. "We have a right to presuppose that in the brain, as in other organs of the body, the normal exercise of function is dependent on a perfect maintenance of the anatomical relations of the component structures, and conversely that morbid conditions of these structures must affect the whole economy more or less seriously" (Bucknill and Tuke). In studying brain pathology it must be kept in view that the brain cannot, like the lungs, liver, and kidneys, cast any of its functions on other organs; it must do its own work, rid itself of its effete matter, and of the products of injury or disease, and provide within itself for the resumption of functions the exercise of which has become impaired from whatever cause.

Solutions of continuity, preventing perfect maintenance of the component cerebral tissues, may arise from—(1) idiopathic causes, *i. e.*, causes originating primarily in the brain; (2) traumatic causes (injury to the head); (3) the effects of other neuroses (morbid nerve conditions); (4) adventitious products (tumors, etc.); (5) morbid conditions of the general system secondarily implicating the brain; (6) evolutional conditions of the system concurrently affecting the brain; (7) toxic agents (poisons). In the case of insanity the results of morbid action are confined to the convolutions of the superior surface of the brain, and to the upper part of its lateral aspects; for the most part its base and inferior lateral aspects and the cerebellum are unaffected. It is true that in old standing cases the central ganglia present lesions, but these are for the most part secondary, and are due to the action of disease in the superior convolutions.

1. Idiopathic changes occur from disease affecting the tissues, the cause of which it may be impossible to trace,—as, for instance, acute inflammation, which, however, is not a frequent cause of insanity. Diffused subacute inflammation is held to be a much more fruitful cause, producing increase (sclerosis) of the neuroglia, degeneration of the cells, destruction (atrophy) and displacement of fibres, and aneurism, distortion, and obliteration of vessels.

A large and important class of causes of idiopathic morbid action is due to over-excitation of the brain. The causes of over-excitation of the brain functions are those which, in most works on insanity, are spoken of as "moral" (grief, anxiety, domestic complications, disappointment, terror, sorrow or joy, religious or political excitement, the exercise of the mental faculties by study unduly prolonged or conducted under adverse circumstances) in contradistinction to "physical" causes, —a distinction which implies some material difference in their method of operation. To the most superficial observer, the deformed head of the idiot, and the paralysis of mind and body which follows on the rupture of a cerebral vessel, are coarsely material conditions; but when mental aberration follows on mental excitement, men are prone to regard it more as a derangement of function than as an evidence of deterioration of brain structure. If, however, we give due weight to the results of physiological research, the matter is not quite so obscure. Arguing from the analogies of other organs and from direct observation, there is reason to believe that when the brain functions are being actively exerted there is a dilatation of the vessels and an increased blood supply (hyperæmia) to its superior and lateral surfaces. This functional hyperæmia is caused by the direct action of the cerebral cells, which, along with the sympathetic system of nerves, exercise control over the muscular coats of the arteries, the immediate regulators of blood supply to any given part. Control over muscular tissue implies, of course, control in two directions, dilatation and contraction. Functional hyperæmia is in every respect a healthy condition, one necessary for the provision of temporary nutriment during temporary action, ceasing with the withdrawal of stimulus, when the calibre of the vessels is reduced to its original dimensions through the contracting influence of the cells. But if the excitement is unduly prolonged a new result appears; the cells themselves become exhausted, and therefore, even if the stimulus is withdrawn, they are unable to assert their ordinary control over the arterial muscular coats in the direction of contraction, so that the increased blood supply continues although the stimulus which caused it has been removed. Instead of functional hyperæmia we have a hyperæmia caused, not by functional excitement, but by exhaustion of the controlling organs. In a minor degree the results of this condition are matters of everyday observation; over-taxation of the brain functions, by study for instance, is very generally followed by sensations of fulness and aching of the head, loss of sleep, and general exhaustion,—a condition which is recovered from when the primary irritation is withdrawn, *i.e.*, when the arteries reacquire healthy tone. But if relief from the causes of irritation is not obtained, a sequence of events ensues tending to deterioration of tissue. In the first place, sleep, the condition necessary for rest and recuperation of the cells, becomes unattainable. Physiological research has shown that during sleep the supply of blood to the brain is diminished (anæmia), that anæmia is necessary for, and hyperæmia is inimical to, its production. Further deterioration of cell activity follows on non-recuperation, and concomitant diminished control over the vessels tends to the establishment of morbid hyperæmia and more or less blood stagnation (stasis). It would be far beyond the compass of this article to follow out in detail the various pathological processes which ensue on paralysis of vaso-motor action; two only need be alluded to—(1) the various changes which take place in the behavior of the constituents of the blood, producing congestion and greater or less obstruction to its normal distribution, and (2) the effects which congestion produces on the lymphatic system of the brain, the system by which effete matter is largely removed from it. It is now generally recognized that the lymphatics of the brain are perivascular, *i.e.*, that they are tubes surrounding the arteries, patent under ordinary conditions; when, however, the arteries are distended, it is easy to comprehend that the lymphatic system becomes occluded by the artery filling up the space provided for it, and therefore that the removal of waste products becomes difficult or impossible. It is a pathological axiom that the structural integrity of a part is dependent on the maintenance of its vascular unity, in other words, on the regular supply and withdrawal of blood by its regular channels. This if impaired or destroyed is necessarily followed by histological changes and by disturbance of function.

By this exposition of a probable sequence of pathological events it is desired to indicate that disturbance of function directly referable to over-excitation of the brain is not a mere functional derangement, not a mere morbid increase of a normal emotion, but that it is the manifestation of a pathological condition,—that, in effect, so-called moral causes may be the producers of physical cerebral disease. This meets with support from the clinical observation that, with very rare exceptions, a considerable period of time elapses between the incidence of the moral cause and the first indication of mental alienation,—an interval during which sleep has been absent in consequence of continued hyperæmia. Instances of melancholy or mania being suddenly produced by mental shock must be searched for in works of fiction. Sudden fright, more especially, is stated to produce immediate convulsion, epilepsy, and catalepsy, but not insanity; except in certain comparatively rare instances, in which it appears to induce with great rapidity a cataleptic mental state, presently to be spoken of as acute primary dementia. Over-exercise of the intellectual function is not by any means such a prolific cause of brain disease as undue emotion. It is not work but worry that kills the brain. When both are combined the result is often rapid.

On the removal or persistence of congestion depends the issue of a case—recovery, or further and permanent solution of continuity. Unless relief is soon obtained, the changes in the cells are followed by lesions of other brain structures which are productive of important pathological conditions affecting the general system; these in their turn render recovery more difficult or impossible, or may even cause death. (For a full account of the various lesions found in the brains of the insane, consult Bucknill and Tuke, *Manual of Psychological Medicine*, 4th ed., cap. vi.; Fox's *Pathological Anatomy of the Nervous Centres*, London, 1874; J. Batty Tuke, "On the Morbid Histology of the Brain and Spinal Cord as observed in the insane," *Brit. and For. Medico-Chirurgical Review*, 1873–74.)

2. The second class comprises all accidents and injuries affecting the brain, and is most conveniently termed *traumatic*. Violence to the head may produce fracture of the skull with or without depression, extravasation of blood in or on the brain, or concussion. There is no relation between the apparent extent of the injury and the results in insanity; extensive fractures of the frontal, lateral, and superior surfaces of the skull, even when complicated with rupture of the envelopes and loss of brain matter, are not, taken over all, more productive of insanity, if so much so, as the apparently less serious condition of concussion. The reason of this is not far to seek; by the open wound free egress is afforded for extravasated blood and the products of inflammation, whereas in concussion, which may also involve extravasation of blood in or on the brain, foreign substances have no means of escape, and so may set up morbid action of a grave nature. Occasionally insanity follows rapidly on the injury, but much more frequently weeks or even months elapse before development of mental symptoms amounting to insanity. During this period morbid action is proceeding on the inner surface of the skull, in the membranes, or in the brain itself. On the inner table of the skull bony growths may be in process of formation, subacute inflammation of the membranes may be going on, and from the same cause the brain may be undergoing progressive changes generally in the direction of sclerosis, *i.e.*, increase of connective tissue.

3. The nervous diseases in the train of which insanity occasionally follows are Epilepsy, Hysteria, and Locomotor Ataxy. In the case of Epilepsy the brain lesions are doubtless the result of the frequently asphyxiated condition of the patient and of the blood poisoning due to the retention of carbonic acid gas (see EPILEPSY). As might be expected, lesions of the arteries in the form of hypertrophy of their coats is frequently observed. The canals in the brain matter through which the vessels pass are very frequently found dilated to from two to six times their normal dimensions. If the richness of the blood supply to the gray matter is considered, this condition of dilatation must imply an immense loss of brain tissue; moreover, the cells are frequently found suffering degeneration. In dealing with the subject of Hysteria, we have, as stated in the article especially bearing on the subject (HYSTERIA), to do with a disease which, although marked by very prominent symptoms, possesses no anatomical seat, and thus when the disease amounts to insanity we are equally in the dark as to the cerebral conditions. The insanity following or accompanying hysteria is not a fatal one in its earlier stages, and there is no report extant of an autopsy on a recent case of this disease. Locomotor Ataxy is a disease of the spinal cord, sclerosis of its posterior columns (see ATAXY). It implicates other parts of the nervous system,—for instance, the optic tracts and nerves. Insanity occasionally is concurrent with, and probably, if not certainly, is produced by an extension of the sclerosis to the cerebral convolutions. This theory meets support from the fact that the mental symptoms associated with locomotor ataxy resemble very closely those of general paralysis, in which hypertrophy of the connective tissue of the superior convolutions has been demonstrated.

4. By the term adventitious products it is meant to indicate all forms of tumors of the brain, skull-cap, and membranes. Such foreign bodies have three distinct effects on the brain structure:—"1st, They create an irritation tending to ramollissement in the nerve substance, with which they are in contact from their first appearance. 2d, They cause pressure on distant parts, which in its turn causes an alteration of the structure and nutrition. 3d, They set up progressive disease and degeneration of certain parts of the nerve structure, the true nature of which is as yet not very well known; but it seems to be in some way directly connected with the essential nature and constitution of all sorts of nerve substance, whether cells or fibres. Its results pathologically are an increase of the connective tissue in the form of granules, and enlargement and thickening of the coats of the blood-vessels; but all these seem to be secondary changes" (Coulston, "On Tumors of the Brain," *Journal of Mental Science*, vol. xviii.). Apoplectic clots are practically tumors.

5. Morbid conditions of the general system secondarily implicating the brain. It is of great interest from an etiological point of view to note that insanity is seldom if ever the immediate result of diseases of individual organs, but that it is more or less intimately associated with those forms of disease which result from a general constitutional instability, such as tuberculosis, rheumatism, gout, and syphilis. There are many diseases painful in character and very depressing to the nervous system, such as stone, fistula (in fact all the so-called surgical diseases of the rectum and bladder), cancer of the uterus, etc., which might be presupposed to be probable causes of insanity, yet in point of fact are not inimical to mental health. They may be so indirectly, inasmuch as they prevent sleep, but even in this wise their effect is very slight. Nor does there appear sufficient reason to connect diseases of the heart, liver, kidneys, directly with insanity. Much stress has been laid on diseases of the uterus and ovaries, and more especially on tumors of these organs, being the primary factors in the production of insanity. Skae laid down as a special form ovario- or utero-mania; and Wergt of Illnau has described the various morbid conditions of the female organs of generation found on post-mortem examination, and has connected with them mental symptoms. But authors on gynæcology make no mention of insanity being a sequela of uterine disease, except in so far as the mental depression which in most women follows on the knowledge that they are affected by serious, perhaps fatal, disease, and the pain and anxiety inseparable therefrom, may produce sleeplessness, and consequent melancholy; and there is no proof of such tumors exercising an extensive influence on causation by peripheral irritation. The fallacy has in the great majority of instances probably arisen from the observation often made in asylums that insanity arising from whatever cause is conditioned by the presence of uterine growths, and that delusions of a sexual character may arise from the sensations thereby produced. Of the very few instances on record in which a direct connection between uterine disease and insanity has been traced may be cited a case reported by Van der Kolk, in which deep melancholy and prolapsus uteri coexisted; the mental symptoms were at once relieved by the organ being restored to its normal position. Such cases are very rare.

It is still a moot point whether a true tubercular or phthisical insanity exists; if it does, it certainly does not arise from tubercular deposits in the brain—a very rare condition in the insane. Those authorities who deny the existence of phthisical insanity hold that, although mental symptoms do frequently present themselves in cases of consumption, and although consumption is very frequent amongst the insane, the insanity is not directly dependent on the diathesis, but more probably results from the general lowering of the system, and at most is only conditioned by the primary disease. In the case of rheumatism and gout there are strong reasons for believing that an actual translation (metastasis) of the *materies morbi* occasionally takes place from affected joints to the connective tissue of the brain and cord,—the evidence being choreic movements of the limbs (St. Vitus's Dance) accompanied by acute mental symptoms, both of which disappear contemporaneously with the return of inflammatory swellings of the joints. Syphilis may act on the brain by the production of tumors (which, however, do not differ in their effects from those of other adventitious products), and by specific changes in the coats of the arteries, which become thickened and even occluded. As a consequence the tissues in their neighborhood suffer deterioration.

The pathological relation between sun-stroke (insolation) and brain disease has not been ascertained. A certain amount of brain congestion has been observed, but not invariably. The cerebral lesion is more probably due to the extreme depression of the whole nervous system; but the *modus operandi* is unknown.

The morbid condition of the general system which most frequently implicates the brain is anæmia, not itself a disease, but the result of many diseases, such as fever, and of such drains on the constitution as lactation (suckling) and imperfect nourishment. The operativeness of these drains may be assisted by overwork under unhealthy conditions. As a typical example may be cited the dress-maker, poorly paid, poorly fed, working for many hours daily in an ill-ventilated room, and sleeping in an unhealthy garret. The term anæmia is not used here to indicate a condition antithetical to hyperæmia—it does not imply any mechanical deprivation of blood supply; on the contrary, the amount of blood, such as it is, is not reduced in quantity. The temporary mechanical anæmia which results from extreme cold produces its effects rapidly,—short delirium and profound sleep. But it is qualitative anæmia, an impoverished state of the blood, which produces more or less permanent results on cerebral health. Inanition acts rapidly on the brain: in the case of those cast away at sea on rafts or in boats the general story is that of short delirious mania, suicide, or death from nervous exhaustion, before emaciation (*i. e.*, before the reserve food of the system is consumed) takes place. So in cases where inanition is more slowly produced, the nervous system is first depressed. And here the position becomes somewhat complicated; for not only is, under such circumstances, the relative amount of the blood constituents different from the normal standard, but its corpuscular elements change in quality; they acquire a degree of viscidity which tends to cause the red corpuscles to coalesce and hang together, and the white to lag and wander into surrounding tissues; and further, this unphysiological behavior of the corpuscles is apt to become aggravated in regions whose nervous energy is depressed. Anæmia thus acts and reacts in procuring a condition of stasis.

6. The effects of evolutional periods concurrently affecting the brain: puberty, adolescence, utero-gestation, the climacteric period, and old age. "Although from the time when the human being comes into the world to the final cessation of his corporeal existence the various functional operations of organic life are carried on with ceaseless activity, whilst those of animal life are only suspended by the intervals of repose which are needed for the renovation of their organs, yet there are very marked differences, not only in the *degree of their united activity* but also in the *relative degrees of energy which they severally manifest* at different epochs" (Carpenter's *Principles of Human Physiology*, chap. xviii.). These differences in degree imply physiological modifications of nutrition, and the observation of ages has caused it to be accepted as a fact in the etiology of disease that numerous and various degenerations occur contemporaneously with such modifications, more especially in the subjects of diathetic conditions. The development of phthisis during adolescence, and of cancer amongst persons at the climacteric period, may be cited as instances. It may be freely admitted that the nexus between the physiological and the pathological position is, as regards certain of the periods, obscure, and that it is dependent more on induction than on demonstration; but it may be pleaded that it is not more obscure in respect of insanity than of other diseases. The pathological difficulty obtains mostly in the relation of the earlier evolutional periods, puberty and adolescence, to insanity; in the others a physiologico-pathological nexus may be traced; but in regard to the former there is nothing to take hold of except the purely physiological process of development of the sexual function, the expansion of the intellectual powers, and rapid increase of the bulk of the body. Although in thoroughly stable subjects due provision is made for these evolutional processes, it is not difficult to conceive that in the nervously unstable a considerable risk is run by the brain in consequence of the strain laid on it. Other adjuvant influences may be at work tending to excite the system which will be spoken of when the insanity occurring at these periods is described. Between the adolescent and climacteric periods the constitution of the nervous, as of the other systems, becomes established, and disturbance is not liable to occur, except from some accidental circumstance apart from evolution. In the most healthily constituted individuals the "change of life" expresses itself by some loss of vigor. The nourishing (trophesial) function becomes less active, and either various degrees of wasting occur, or there is a tendency towards restitution in bulk of tissues by a less highly organized material. The most important instance of the latter tendency is fatty degeneration of muscle, to which the muscle of the arterial system is very liable. In the mass of mankind those changes assume no pathological importance: the man or woman of middle life passes into advanced age without serious constitutional disturbance; on the other hand, there may be a break down of the system due to climacteric disease of special organs, as, for instance, fatty degeneration of the heart. In all probability the insanity of the climacteric period may be referred to two pathological conditions: it may depend on structural changes in the brain due to fatty degeneration of its arteries and cells, or it may be a secondary result of general systemic disturbance, due to cessation of menstruation in the female, and, possibly, to some analogous modification of the sexual function in men. The senile period brings with it further reduction of formative activity; all the tissues waste, and are liable to fatty and calcareous degeneration. Here again the arteries of the brain are very generally implicated: atheroma in some degree is almost always present, but is by no means always followed by insanity. Whewell retained his faculties to the last, notwithstanding that his cerebral arteries were much diseased. Still this condition must be taken into account in studying the causation of senile insanity, as it necessarily implicates the nutrition of the brain. It must assist in preventing recuperation of the cells; it may in certain instances diminish suddenly the blood supply to a particular area; but the stronger probability is that senile mental decay lies at the door of senile degeneration of the cells.

The various and profound modifications of the system which attend the periods of utero-gestation, pregnancy, and child-bearing do not leave the nervous centres unaffected. Most women are liable to slight changes of disposition and temper, morbid longings, strange likes and dislikes during pregnancy, more especially during the earlier months; but these are universally accepted as accompaniments of the condition not involving any doubt as to sanity. But there are various factors at work in the system during pregnancy which have grave influence on the nervous system, more especially in those hereditarily predisposed, and in those gravid for the first time. There is modification of direction of the blood towards a new focus, and its quality is changed, as is shown by an increase of fibrin and water and a decrease of albumen. How much these changes structurally affect the encephalon may be deduced from the fact of the presence of bony plates (osteophyte) on the surface of the dura mater and the inner table of the skull, and how much functionally, by constant congestions and flushings. To such physical influences are superadded the discomfort and uneasiness of the situation, mental anxiety and anticipation of danger, and in the unmarried the horror of disgrace. In the puerperal (recently delivered) woman there are to be taken into pathological account the various depressing influences of child-bed, its various accidents reducing vitality, the sudden return to ordinary physiological conditions, the cessation of the occasional physiological condition, the rapid call for a new focus of nutrition, the translation as it were of the blood supply from the uterus to the mammæ,—all physical influences liable to affect the brain. These influences may act independently of moral shock; but, where this is coincident, there is a condition of the nervous system unprepared to resist, or, it may rather be said, prepared to succumb.

7. Among the toxic agents which affect the brain, alcohol holds the foremost place. On the action of this poison the article DRUNKENNESS supplies full information. Considerable difficulty exists as to the estimation of the importance to be attached to alcohol in the production of brain disease from the fact that excess in the use of stimulants is very frequently a symptom of incipient insanity, and that the symptom is often mistaken for the cause. The habitual use of opium and Indian hemp (*Cannabis indica*), which first stimulate and then paralyze the action of the cerebral cells, is a frequent cause of lesion.

Difficulties may arise in individual cases in establishing a theory of causation from the presence of what are generally spoken of in systematic works on insanity as "mixed" causes, *i. e.*, the presence of two morbid factors in one individual. So long as these consist in variety in character of excited psychical action, such as grief and anxiety of business, over-prolonged study and domestic affliction, the combination does not affect the position; but when we have a history of one or more of such psychical influences being associated with a depraved condition of the general system, with poverty, with excess in alcoholic stimulants, or with hereditary predisposition, it appears at the first glance difficult to assess the value to be attached to each in the production of brain disease. This complication is, however, more apparent than real; weakness of the system, whether produced by disease or by malnutrition, only implies a condition in which cerebral degeneration is more likely to occur, but where there is no reason to believe it would have occurred if the brain, weakened along with the other organs of the body, had not been subjected to over-excitation. It may be argued that the brain excitation would not have produced the lesion if the tone of the general system had not been lowered: that is as it may be,—it is a proposition which cannot be accepted or denied positively in the absence of positive data. But negative data obtain which warrant its refusal. These are twofold:—a depraved condition of the general system is a frequent result of over-excitation of the brain, the result being liable to be mistaken for the efficient cause; and the history and symptoms of insanity resulting from special morbid conditions of the system differ materially from those produced by over-excitation.

The action of all these varied morbid factors is in the direction of solution of continuity of cerebral elements, and consequently of perversion of psychical function. And here a wide gap opens itself in the study of brain pathology in its relation to morbid psychology. No adequate theory has been advanced to account for the sequence of a particular type or train of morbid mental symptoms on a particular morbid condition of the brain. In the most definite forms of insanity, those of which the morbid anatomy is pretty definitely determined, there is not the slightest suggestion afforded of the causation of the peculiar type of mental symptoms which symptomatize them, or for the alternation of symptoms in an individual case, or for diversity of symptoms apparently starting from the same cause. All that is known is that when the hemispherical ganglia are diseased we may have excitement or depression of feeling, delusion, or obfuscation of the intellectual and moral qualities; but why in one case excitement, in another delusion, and in a third both, is an utter mystery.

Classification.

The mental symptoms of acquired insanity have been classified from the time of Pinel—it might, save from some slight difference in the application of the terms, be said from the time of Hippocrates—as mania, melancholia, and dementia, according as exaltation or depression of feeling or weakness of intellect presents itself most prominently in a given case. To these has been added delusional insanity, spoken of by certain authors as monomania. Numberless classifications founded on psychological considerations have been advanced, involving, however, more variety in terminology than in principle; all such, when analyzed, are reducible to the primitive mania, melancholia, and dementia. Pritchard asserted that mental symptoms were divisible into two great classes, according as the intellectual and moral faculties were implicated. This principle falls to the ground from the simple but most important fact that the primary symptom in all insanities is perversion of the moral sense, and that this perversion pervades all cases of mental disease to their termination. This change of morale amounts to various degrees of perversion of the ordinary character and disposition of the individual. He becomes indifferent to social considerations, apathetic and neglectful of the personal and family duties, evinces dislike and suspicion of friends and relatives, and may betake himself to excess in alcoholic stimulants and other forms of dissipation. There is a general concentration of his ideas on himself, which is often spoken of as the selfishness of the insane. According to the direction in action in which perversion of the moral sense is manifested such so-called forms of insanity have been constructed as dipsomania, kleptomania, erotomania, etc., which, however, are to be regarded as merely accidental phenomena. Moral insanity may appear to exist alone at certain times in certain cases, but it is greatly to be doubted whether it really ever exists apart from intellectual perversion. The mere fact that a person cannot appreciate the change in himself, cannot, as it were, disapprove of his own actions, is evidence that the moral faculties are not alone implicated. The converse proposition may be stated even more strongly—intellectual insanity never exists without moral perversion.

Moral perversion is, however, only one of the initial symptoms. In most insanities a "period of incubation" is observed, generally spoken of as the prodromal or initial period. Sudden and violent outbursts of insanity are occasionally reported, but, when these are carefully examined into, a train of prodromal symptoms, physical as well as psychical, can almost invariably be traced. These symptoms are for the most part insidious in character. Founding on the statements of patients suffering from premonitory symptoms, on those made by others, who, having recovered, are able to carry back their recollection to the incidence of the prodromal stage, and on the direct observation of the physician, physical indications are the first to present themselves. These consist in a feeling of fulness in the head, throbbing of the forehead and eyeballs, flashes of light before the eyes, and general malaise. The mental symptoms follow closely, and consist, in addition to the change in morale already spoken of, in restlessness, irritability, inability to apply the mind to the everyday affairs of life, and sleeplessness. In certain forms this description of the prodromal symptoms requires some slight modification. They are very generally accompanied by impairment of general health.

The classification of the insanities according to the predominant mental symptom is adopted in almost all treatises on the subject; but there is a growing conviction that this basis is neither so scientific nor so convenient as a classification based on pathology. Mania, melancholia, and dementia are merely symptoms of brain disease. If these symptoms were constant in even a considerable majority of all cases, there would be better warrant for employing them as a basis of nosology; but they vary so widely in kind and degree, they run so closely one into the other, they may all appear in an individual case within so very short a space of time, that their use is generally misleading, even as indicating the mental condition of a patient. In many cases of insanity mania may present itself to-day, melancholia to-morrow, and dementia the day after, being, in fact, indications of the course of the complaint. It is undoubtedly true that in a proportion of the insane there is a general predominance of one or other of these conditions, but it is equally true that there is an equal proportion in which the application of any one of these terms is open to question. Thus we may have a melancholic mania or a maniacal melancholia. Moreover, there are many forms of insanity of which the connection with the causation is so intimate that even those authors who adhere to the archaic classification cannot refuse to acknowledge them as pathological classes, and are compelled to treat of them under their pathological designations; puerperal insanity, epileptic insanity, senile insanity, and general paralysis may be cited as prominent examples. To say of a man that he is maniacal is not saying more than to say of one who has lost power over his limbs that he suffers from palsy, a diagnosis which no scientific physician of the present day would be content with, as it conveys no definite idea as to the pathological character or cause of impairment of mobility. It may be freely admitted that medical science is not yet able to base a nosology of the insanities on the highest pathological platform, that of morbid anatomy. Considerable advances have been made in this direction, but the observations of pathologists, with the exception of those bearing on three or four classes of brain disease, are vague and quite insufficient for the purpose. Clinical observation, however, has served to relate symptoms with cause to such an extent as to enable the observer of mental disease to fall back on the second pathological position—etiology, and has enabled him to assert, in a very large proportion of cases, causation as a scientific and convenient standpoint for classification. After all, classifications are matters of convenience. It is not asserted that the classification adopted in this article is more than provisional; but it is asserted that it is more convenient to study the insanities in connection with the bodily conditions of their subjects than to rely on a general description of mental symptoms which are inconstant in kind and degree, and often so complex as to render analysis impossible.

When Esquirol's definition of the mental conditions is quoted, little more need be added, for further description would merely involve an amplified account of psychological peculiarities. Esquirol thus describes the conditions:—(1) Melancholia, or, as he terms it, Lypemania, disorder of the faculties with respect to one or a small number of objects, with predominance of a sorrowful and depressing passion; (2) Monomania, in which the disorder of the faculties is limited to one or a small number of objects, with excitement, and predominance of a gay and expansive passion; (3) Mania, in which the insanity extends to all kinds of objects, and is accompanied by excitement; (4) Dementia, in which the insensate utter folly, because the organs of thought have lost their energy and the strength requisite for their functions. In 1852 Schroeder van der Kolk and in 1860 Morel laid the foundation of a classification more in accordance with pathological science. The former included the different forms of the disease under two great classes:—"idiopathic insanity," comprising all cases produced by primary affections of the brain; and "sympathetic insanity," including those due to morbid conditions of the general system. Morel divided the insanities into six groups:—(1) hereditary insanity; (2) toxic insanity; (3) insanity produced by the transformation of other diseases; (4) idiopathic insanity; (5) sympathetic insanity; (6) dementia, a terminative stage. Notwithstanding faults of detail, it may be fairly said that these propositions marked a great advance in the study of insanity, and that all later classifications based on the same principles have been derived from study of them. The following system admittedly is so.

I. Idiopathic insanities.	Idiopathic mania, melancholia, and dementia. General paralysis of the insane.
II. Traumatic insanity.	
III. The insanities associated with other neuroses.	Epileptic insanity. Hysterical insanity. Hypochondriacal insanity.
IV. Insanity resulting from the presence of adventitious products.	
V. Insanities resulting from morbid conditions of the general system.	Phthisical insanity. Rheumatic insanity. Gouty insanity. Syphilitic insanity. Insanity from sunstroke. Anæmic insanity.
VI. Insanities occurring at evolutional periods.	Insanity of pubescence and adolescence. Climacteric insanity. Senile insanity. Insanity of pregnancy. Puerperal insanity.
VII. Toxic insanity.	

I. IDIOPATHIC MANIA AND MELANCHOLIA.—It is proposed to consider under the head of idiopathic mania and melancholia the large and important class of cases which result from over-excitation of the brain due to so-called moral causes. In considering this form of insanity, a difficulty arises in reconciling the dependence of two such apparently widely divergent morbid psychical states as mania and melancholia on one common pathological condition. That they are so is maintained by the following clinical observations—1st, that during the prodromal period, *i. e.*, the period during which over-excitation is using its influence on the brain tissues, the symptoms of excitement and depression generally alternate; 2d, that in certain acute cases mania and melancholia coexist, that is to say, it is impossible for the observer to say whether they are cases of maniacal melancholia or melancholic mania; 3d, that, as many cases run their course towards recovery, the symptoms are consecutively mania, melancholia, and dementia; 4th, that the effects of irritating poisons applied to the brain, alcohol markedly, produce these symptoms in some individuals in a very short space of time. These observations point, not to a difference of pathological causation, but to variation in symptoms in conformity with the progress of pathological processes. It must be borne in mind that congestion is not a condition constant in quality or in quantity, and, further, that it is an inconstant condition acting on an inconstant subject, and therefore productive of cumulative inconstant results. Brain congestion, due to over-excitation, produces functional excitement of that organ. It must be remembered that although mania is accompanied by exaltation, and melancholia by depression of feeling, they are both manifestations of excitement of feeling. Given this common psychological condition of excitement, a reason must be sought for the variety of its manifestation either in some peculiarity of the irritating cause or in some idiosyncrasy of the affected individual. In either case no material assistance is gained from psychological considerations, for there is no necessary connection between depressing emotions and melancholia; intense grief often produces acute mania, and the insanity of the man of saturnine mind is as often as not characterized by mania. The peculiarity of the irritating cause appears to be, not its psychological characteristic, but its intensity. The more rapidly excitement of feeling is produced, the more likely is mania to be the symptom of the insanity. That melancholia often supervenes on depressing emotions gradual in their incidence does not imply a psychological nexus, but that, as their irritating influence is slowly applied, so the results of the irritation are slowly produced, and (as in the case of every tissue of the body) there is variety of degree of symptoms in conformity with the rapidity of the progress of pathological events. There are also various underlying conditions difficult to treat of in the mass, any one of which may have considerable bearing on an individual case. Constitutional predisposition (diathesis) may render a person more prone to the subacute forms of disease, and the condition of the body at the time of irritation may influence the nature of the symptoms in either direction. In the absence of the possibility of applying to the brain the mechanical aids which have given the physician an insight into the sequence of pathological events occurring in other organs, the pathologist has nothing to depend on save clinical observation. He has presented to him a diseased organ, complex in function, of the physiology of which he is, as regards its psychical action, profoundly ignorant; all he can say is that, when its histological integrity is impaired, he has reason to believe that "some functions become torpid and oppressed, while others are excited into preternatural activity" (Bucknill and Tuke). It must be stated, however, that in a considerable proportion of cases the nature of the ultimate condition is foreshadowed from the very commencement by the character of the initial symptoms. Simple depression of feeling may be the first and last symptom of insanity, or it may gradually increase in intensity till it attains the extreme and most complicated form of melancholia. In like manner simple excitement and exaltation of feeling may characterize a case from beginning to end, or it may culminate more or less rapidly in active mania, without the intervention of other psychical symptoms.

As to the duration of the prodromal period, in the mass of cases nothing can be stated with certainty; it can only be said that, as a general rule, the incidence of melancholia is more slow than that of mania. Putting aside exceptional cases, it may be stated that, whereas the former is a matter of months or weeks, the latter is a matter of weeks or days.

The initial mental symptoms having been already described, it remains only to say that the general system becomes coincidentally affected; functional disturbances of the digestive organs soon manifest themselves, and the nutrition of the body becomes defective. To this implication of other systems consequent on impairment of the trophesial (nourishment-regulating) function of the brain can be traced a large amount of the errors which exist as to the causation of idiopathic melancholia and mania. Very frequently this secondary condition is set down as the primary cause; the insanity is referred to derangements of the stomach or bowels, when in fact these are, concomitantly with the mental disturbance, results of the cerebral mischief. Doubtless these functional derangements exercise considerable influence on the progress of the case by assisting to deprave the general economy, and by producing depressing sensations in the region of the stomach. To them may probably be attributed, together with the apprehension of impending insanity, that phase of the disease spoken of by the older writers as the *studium melancholicum*, which so frequently presents itself in incipient idiopathic cases.

During the earlier stages of the prodromal period it is impossible, in the majority of cases, for the physician to predict, with anything like certainty, whether the case may culminate in acute melancholia or acute mania. But as it progresses the irritability and restlessness which ushered in the malady become intensified; sleep is either irregular or may be lost for nights together; further degeneration of the brain constituents necessarily follows, and the loss of controlling power over ideas is manifested in excitement in one of two ways—(1) by the domination of one set of ideas, which are for the most part of a depressed character, or (2) by a tendency to follow lines of thought suggested by accidental external circumstances. Although in the one case there is a concentration and in the other a diffusion of ideas, there is the common result of occlusion of the individual from a normal process of thought, in consequence of his inability to review external circumstances correctly.

1. *Acute Idiopathic Melancholia* presents itself in three degrees of intensity:—(1) simple depression of feeling, (2) depression of feeling with delusion, (3) depression of feeling with mania or delirium. The second and third of these conditions may supervene on the first, or any one of them may singly characterize the case.

Simple Depression of Feeling.—In no form of insanity is the sane mind more prone to project a psychological scheme of causation than in that of which simple depression of feeling is the predominant symptom. The restlessness and irritability which accompany anxiety, grief, and worry, and the consequent exhaustion and depression, suggest a psychological continuity. There is, however, a very distinct difference between depression of feeling within the limits of health and the depression of feeling resulting from morbid processes going on in the brain, and in symptoms there is a distinct line of demarcation. A mere fit of depression, from whatever cause, does not prevent a man from using his intellectual faculties; circumstances influence him, and he can review his position; but where the limit of health is passed the normal influence of external circumstances is lost. This indication is accompanied by a gloomy apathy; the memory of the past is misery, the present is unendurable, and there is no hope in the future; everything is black within and without, every incident feeds the melancholy, every suggestion of hope is parried, and every appeal to the reason falls dead on the ear of the sufferer. This latter symptom—the inoperativeness of appeals to the reason—is a feature of all forms of insanity, and it is therefore well to notice it particularly when treating of the simplest. What to the sane mind is the simplest proposition, to the insane appears either utterly false in itself, or to have no bearing on the position. The power of comparing idea with idea, the faculty of discriminating their differences, or the perception of agreement in the midst of difference is lost—in a word, the judgment is impaired or utterly in abeyance. The common everyday expression "out of his judgment," employed to indicate that a man is insane, is psychologically accurate, and logically applicable in all forms of insanity. A strong tendency to suicide frequently presents itself; the utmost ingenuity is exercised to accomplish this object, the whole mental energies being concentrated upon it. It is impossible to render in terms the general as well as facial expression of the melancholic; it cannot be simulated with success before any one conversant with the condition.

Depression of Feeling with Delusion.—Idiopathic melancholia symptomatized by simple depression of feeling may become gradually complicated with delusion and hallucination, or this complicated condition may follow immediately on the initial symptoms. The delusions and hallucinations of idiopathic melancholia may be divided into three classes:—(1) those traceable to perverted sensation produced by implication of the functions of the general system; (2) those apparently dependent on the nature of the primary causating train of emotion; and (3) those which it is impossible to connect with any particular influence, either psychical or somatic. The first class contains the delusional symptoms resultant on atony of the alimentary canal, which, by producing obstinate constipation, catarrhal affections of the stomach and bowels, and dyspepsia, cause sensations which are referred by the insane mind to supernatural influences: he believes that he has serpents or worms inside him, that his gullet is closed, or that his bowels are so obstructed as to render relief by the natural passage impossible. As a direct result of this delusion food is systematically refused, and it often becomes necessary to resort to artificial feeding by the stomach-pump or some allied apparatus. Hallucinations and illusions of smell and taste may be referred to the same causes as the delusions just spoken of: the fœtor of the breath due to dyspepsia may suggest to the melancholic that he is surrounded by a poisonous atmosphere, and that everything near him stinks; and the foul tongue of the same condition may be productive of hallucinations of taste, and may even lead up to the very common delusion that his food is poisoned. Such distinct objective starting points, however, do not suggest themselves for hallucinations of vision and hearing; these can only be regarded as incidental results of the morbid cerebral condition of which the process of production is unknown. Hallucinations of sight are comparatively rare; when they do occur it is generally in the form of spectres, which prompt to suicide, self-mutilation, or homicide. Hallucinations of hearing are more common, and are believed to be of graver import. As a rule the hallucination takes the form of words emanating from a something or some one of whose personality the patient has no conception. That an apparent connection can often be traced between the character of the delusion and that of the primary causating emotion is particularly true of the melancholic delusions which follow on religious emotionalism, so much so that many writers regard religious melancholia as a distinct form of insanity. This is a term, however, very loosely employed, and it is, in fact, by no means easy to ascertain what it implies; by one section of authors it is regarded as that form of melancholia in which the insanity centres upon religious ideas, by another as the form of insanity produced by depressing religious emotion. The latter position is tenable on purely clinical considerations, if the insanity retains the character of the causating emotion, which it very frequently does not; the former is open to the objection that the delusions may be mere accidents in a case, and may bear no relation whatever to the exciting psychical cause. One reason why the term is so strongly impressed on the mind of the public is, that it may appear as pseudo-epidemic. The waves of religious emotionalism, which almost periodically disturb society in the form of "revivals," are apt to produce explosion of psychical action in those members of the community predisposed to nervous degradation. The public never considers, in fact does not know, that any other equally potent cause of emotion might be as effectual, and therefore sets down such accidental congeries of cases as "religious melancholia," accepting that term as representing all the abnormal psychical conditions which may result from "revivals." It is better to consider religious influences in the common category of emotions producing over-excitation of the brain. The deep despondency which follows on religious emotionalism may be productive of such predominating ideas as that the soul is irretrievably lost, that the unpardonable sin has been committed, and that there is no hope of salvation. Although in the abstract it is open to question whether such predominating ideas are strictly delusions, inasmuch as they may be considered as morbid exacerbations of fears and anxieties suggested by certain schools of religious thought, still in the concrete they amount to delusion; for, even supposing they have been arrived at by a normal process of reasoning—which in most cases is extremely doubtful—they are maintained at the expense of all other religious considerations, and by the exclusion of all arguments founded on the experience of others

The delusions which it is impossible to connect with any particular physical or psychical influence are for the most part characterized by suspicion and fear, and take such forms in the mind of the patient as that spies surround him, that all his actions are watched, that all connected with him are plotting against him, that conspiracies are being organized with a view to deprive him of his estate, procure his ruin, or do him some evil of which he can give no definite explanation. Occasionally delusions of fear and suspicion are connected with persons whom the patient has never seen, or with sections of society, such as political parties or religious communions. Self-accusation of serious crime is a frequent result of delusion. This idea of crime may be entirely unsubstantial, or it may possess some very slight foundation in fact, one which has no rational bearing on the existing position. When insane self-accusations are critically examined, it is found that remorse is very rarely connected with the real or imaginary crimes, from the consequences of which others have or might have suffered. The poetic stories of insanity produced by remorse of conscience for crimes involving the ruin or disgrace of others than the actual offenders may be set down as in the main apocryphal.

The delusions of the melancholic are often fearfully intense, and produce very serious results in action; they are apt to extend beyond himself. By a process of reasoning which the sane mind cannot appreciate, he may argue himself into the belief that his misery is also the misery of his friends and family, that his relatives are cognizant of or implicated in his imaginary crimes, and that they must suffer the consequences along with him. As death offers to him the only chance of relief, so he believes it best that those nearest and dearest to him should die also. From this state of feeling follow those fearful acts of homicide which occasionally startle society—a parent destroys several of his children, a lover his mistress, or a husband his wife, before committing self-destruction. It is as well to attract attention here to the appearance of a tendency to homicide and suicide as an incident in a case, as the subject will have to be recurred to when adverting to the question of homicidal and suicidal insanity.

Depression of Feeling associated with Delirium or Mania.—In this class of cases it is impossible to say whether they should be called melancholic mania or maniacal melancholia. The wildest delirious excitement coexists with the deepest depression of feeling; delusions of fear and horror are given expression to in the most extravagant manner, and relief from them is sought in frantic attempts at suicide; the patient dashes his head against the floor or wall, tries to cast himself down stairs, holds his breath in the hope that he may suffocate. In this condition there is a strong tendency towards death, which not unfrequently occurs within a few days of the development of the graver symptoms, and which is generally produced by congestion of the lungs as a direct result of the cerebral condition, *i. e.*, by a true cerebral pneumonia.

2. *Acute Idiopathic Mania* presents itself in three forms—(1) simple exaltation of feeling, (2) exaltation of feeling with delusion, (3) acute delirious mania. The second and third of these psychical conditions may supervene on the first, or any one of them may singly characterize a case; in all, the period of transition from the prodromal stage is much more rapid than in acute idiopathic melancholia.

Simple exaltation of feeling manifests itself in all degrees of intensity between mild general excitement and the extreme forms of maniacal furor; in kind it may not amount to more than a decided increase of the initial symptoms of restlessness, irritability, and change of disposition; in degree it is characterized by greater or less excitement of thought, word, and action. The general vague restlessness and irritability of the prodromal period not only become exacerbated, but manifest a tendency to produce results in action. Excited action may show itself either in a general exaltation or in the suspension of normal trains of thought. A prominent example of the first psychical condition is found in the naturally devout mind under certain conditions of excitement: the habitually religious man may have meditated on schemes for self-conduct, the good of mankind, or the spread of religion, schemes which, so long as mental action was under control, were mere projects, things to be hoped for, but which under morbid excitement assert themselves so powerfully as to be regarded by the unbalanced mind as immediate necessities, to be procured at the expense of all considerations. The real distinction of religious mania from religious enthusiastic excitement consists, not in the form of the ideas, for which parallel cases might be found in sanity and insanity, but in the *per saltum* manner in which it is sought to carry them into action, in the leaving out of those links which the sane mind uses to decide on the adoption or rejection of a scheme, but the omission of which transfers the scheme suddenly from the region of imagination and hope to one of present reality. There is an absence of religious totality; the patient is bound up in some scheme for the advancement of religious knowledge, in some project for the building of a church, the founding of a school, the establishing of a mission, or, more probably, for all at once; for this he neglects his family, all social considerations, and those duties which are the precepts of his faith. Whether the apparently efficient cause be religion, politics, or the prominent social question of the day, the results are identical, being only conditioned by the nature of the original idea. The ordinary behavior of the man is changed; he is ever on the move; his gestures, loud tone of voice, volubility of talk, and general manner are such as to cause his friends distinctly to mark the change. A large proportion of such cases recover under appropriate treatment, but they not unfrequently pass into acute delirious mania. When the disease is manifested by the suspension of the ordinary trains of thought, the symptoms consist, for the most part, in recklessness of action and conversation; there is a sort of exalted joyousness, a strong tendency to dissipation, loud and wild though not necessarily incoherent talk, extreme restlessness, and utter want of respect for all conventionalities. Such patients (reputable members of society, be it remembered, a month or a week before) outrage all sense of decency; they may walk the street with strumpets, and appear drunk in public, forcing their behavior on the notice of the police. They care nothing for the feelings of friends or the prospects of their families. The intellectual faculties may be active; thus wit and humor, uncontrolled by any feelings of consideration for others, may stand out all the more prominently. The condition, taken over all, is very closely allied to that stage of intoxication in which the poison of alcohol sets free all controlling influences. When the restraining power of association is lost, there is no difficulty in comprehending that the uncontrolled brain may act in any direction. This class of cases is specially emphasized, because they are apt to be mistaken by the public for instances of mere moral obliquity.

The relation of amount of mental disturbance to the degree of excitement is not definable; mania may be extreme, and the disturbance of ideas apparently slight, and *vice versa*. It is of great importance that the two following facts should be insisted on—(1) that mania of an extreme description can exist without delusion; and (2) that mania of a dangerous nature may exist without furious excitement. It is in this class of mania that cases of so-called *folie raisonnante* are for the most part met with—a class strongly insisted on by many Continental authorities as of great pathological importance. By one section of foreign writers it is spoken of as *folie raisonnante*, by another under the original name suggested by Pinel *mania sine delirio*, while by a third both are used promiscuously to indicate a class of cases in which, although considerable disturbance and excitement may exist, the sufferer is able to justify his course of action by a line of reasoning not illogical in itself, although founded on false premises.

Exaltation of feeling with delusion or delusional mania, whether it follows on a period of simple exaltation of feeling, or is coexistent with the first symptoms of excitement, is not to be connected with the originating psychical cause; indeed the intellectual confusion is so great and of such a kind as to render any analysis impossible. It is well to mark here the psychological difference between maniacal and melancholic delusions; the latter are persistent in character and appear to proceed from within, the former are changeful and are readily acted on from without. The general expansiveness of ideas, the rapidity with which they are produced and influenced by external objects, along with the inability to correlate idea with idea, are productive of incoherence in thought, word, and action. For instance, a man may imagine and state that he is the king of the universe, at the same time that he enters no remonstrance against herding and eating with his fellow paupers; he may assert his superiority, but may not object to obey the behests of a common keeper.

Acute delirious mania is a condition often rapidly produced and not unfrequently fatal. It may be the culmination of a case which has passed through the stages of simple exaltation of feeling and mania with delusion—the latter rarely; or it may appear in a few days or even a few hours as the result of some severe mental shock. It may persist for only a short time, and is then spoken of as acute transitory mania. The symptoms are very definite,—the wildest yells and screams, a frenzied rushing to and fro, a reckless casting of the body on the ground or against the walls and furniture, smashing everything that comes in the way without any definite purpose save smashing, flushed features, clammy sweat, and a high bounding rapid pulse; nothing can control the patient but physical force, for his fury renders him blind to all influences.

3. *Acute Primary Dementia.*—This disease is of rapid incidence. It may result from sudden psychical disturbance, especially fright; occasionally no cause can be traced. After a few days or hours, during which the patient is somewhat stupid and apathetic, these symptoms increase to such a degree as to cause him to be, to all outward appearance, utterly demented; he sits unaffected by anything that goes on around him; he is completely helpless, cannot take off or put on his clothes nor feed himself, and passes urine and fæces where he sits or stands; he is speechless, and cannot be roused to action by any appeal; his movements are slow, when he can be got to move at all; but the chief motor symptom is a degree of catalepsy. It may be said with truth that the condition is one of mental and bodily catalepsy. Such cases to the ordinary observer appear utterly hopeless. There is a strong tendency towards death; but when this is overcome, it often happens that the sufferer gradually emerges from the condition, and can give an account of the sensations experienced during his illness. It may terminate in dementia of a very low type. Post-mortem examination of recent cases frequently reveals dropsy of the brain, or changes in interstitial tissues producing pressure. (See Blandford, *Insanity and its Treatment;* Bucknill and Tuke, *Psychological Medicine;* Griesinger, *On Mental Diseases.*)

4. *General Paralysis of the Insane.*—General paresis, progressive paralytic dementia, or, as it is more frequently spoken of, *general paralysis*, is a disease of the superior and lateral convolutions of the brain, which gradually extends over the whole nervous system, producing a peculiar impairment of motor power, and invariably accompanied by insanity. It is marked by well-defined series of physical and psychical symptoms, and

terminates in a peculiar manner within a definite period.

General paralysis was first recognized as a special disease in France; it was indicated by Esquirol, and its history was fairly elucidated by Bayle, Delaye, and Calmeil, the latter giving it the name of *paralysie générale des aliénés.* General paralysis is a common disease, and is generally spoken of as "softening of the brain," a term diametrically opposed to its pathological anatomy. The condition is essentially a chronic diffuse subinflammatory overgrowth of the connective tissue of the cerebral hemispheres, leading to destruction of the true nerve elements, and principally affecting that region of the brain in which recent observers have localized the cortical motor centres. General paralysis is said to be a disease of middle life; this is to a certain extent true, for, in the large majority of cases, its incidence occurs between the ages of thirty-five and fifty; it is, however, met with prior to the first-mentioned age, less frequently after the latter period of life. Statistics show that the decade between forty and fifty is the one during which the disease is most likely to occur. Men are more subject to it than women, in the proportion of, at least, eight to one; in women the symptoms are less strongly pronounced, and the disease runs its course more slowly. Although the relative frequency of the disease appears to be equal in the higher and lower classes of society, statistics show that the town artisan is more liable to it than the agricultural laborer. In the lower grades of society general paralysis is much more common in England than in Scotland or Ireland; in certain English asylums general paralytics constitute from a sixth to an eighth of the inmates, whilst in Scotch and Irish district asylums the proportion does not amount to more than 2 or 3 per cent.

The progressive character of the disease is marked by three stages, termed the prodromal, the acute, and the terminative. The *prodromal stage* is marked by a somewhat incongruous congeries of mental symptoms, consisting of total change in the habits and disposition, general restlessness and irritability, impairment of memory, extravagance in thought and action, and a peculiar facility closely followed by, or intercurrent with, the bodily symptoms of impaired mobility of the face and tongue. For the purposes of diagnosis the physical are more important than the mental phenomena. As a rule, the *bouleversement* of disposition is peculiarly well marked; the impairment of memory consists, not only in the blurring and confusion of past events, but in the forgetting of the occurrence of one minute in the next,—purposes formed and intentions expressed are forgotten almost as soon as formed and expressed. This want of fixity is also shown by the non-recognition of the lapse of time, and by the manner in which violent passion is suddenly changed into amiability. To the same cause may probably be traced the peculiar facility of disposition of the general paralytic; even at this early stage there are indications of the optimism which, as the case progresses, affords the characteristic psychical symptom. In the prodromal period it is manifested by a degree of morbid vanity, general exaltation, and a tendency to regard all things in the brightest possible light. The physical symptoms consist in a finely fibrillar action of the muscles of the tongue, twitching of the upper lip, hesitancy of speech, and a loss of facial expression; the tongue symptom consists of a rapid agitation of its surface, the voluntary movements of the whole organ not being entirely under control, *e. g.*, it is protruded with a jerk; the upper lip hangs and trembles before utterance like that of one struggling against weeping; the hesitancy of speech can best be illustrated by saying that it is identical with the slurring of words in the first stage of intoxication,—the patient "speaks thick;" the face assumes a mask-like want of expression—the muscular power being impaired to such a degree as to cause change of expression to be a comparatively slow process. As the disease advances there is greater excitability, and the general exaltation of ideas becomes so great as to lead the patient to the commission of insanely extravagant actions, such as purchases of large numbers of useless articles, or of lands and houses far beyond his means, numerous indiscriminate proposals of marriage, the suggestion of utterly absurd commercial schemes, or attempts at feats utterly beyond his physical powers. Not unfrequently he is found committing theftuous acts. The *acute period* is frequently ushered in by maniacal symptoms which generally assume the type of what is termed by French writers *délire ambitieux.* Delusion of the wildest character may now present itself; the patient may believe himself to be in possession of millions of money, to be unsurpassed in strength and agility, to be a great and overruling genius, and the recipient of the highest honors. Every idea is expanded and exalted, whether it relates to time, space, or personal attributes. Although grandiose and extravagant delusion is very frequent, existing as it does in about one-half of all cases, it is by no means such a persistent symptom as the *bien être*, which condition is the diagnostic of the disease in that it is invariably present. This is shown by perfect contentment with himself and all things around him, by the constant use of superlatives and such expressions as "all right," "splendid," "first rate;" he speaks of his health as robust, "never better in my life," even when there is grave constitutional disturbance; he is unaffected by the death of child, or wife, or nearest friend. He is utterly unsuspicious, lost to all appreciation of social relations, and facile in the extreme. Synchronously with this condition, the physical symptoms become exacerbated; the tongue and facial symptoms already spoken of increase in intensity, and in addition impairments of the motor powers of the extremities present themselves, consisting in a loss of co-ordinating power, not in a loss of muscular strength. Thus the gait becomes straddled and uncertain; there is a widening of the basis of support; he has to pick his steps as he goes up and down stairs, and is apt to trip over small obstacles; the action of walking resembles that of a half-drunk man. Later on the arms become involved. The pupils are often irregular. The third or *terminative stage* is marked by "epileptiform" or more properly apoplectiform attacks, the general condition becoming more and more degraded. By this time the patient is almost bedridden; actual palsy often occurs. Towards the end certain of the semivoluntary muscles are affected; bedsores may form; and he may die slowly of exhaustion or suddenly during an apoplectiform attack. General paralysis runs its course in from one to four years; more rapid and more protracted cases are on record, but, taken over all, eighteen months may be stated as its average duration. The disease is incurable.

II. Traumatic Insanity.—Generally speaking, insanity is not developed for some months or even years after receipt of the injury, but in the interval the patient suffers from headache, more especially after mental effort, irascibility of temper, confusion of thought, and consequent inaptitude for business, weakened memory, and a constant feeling of fatigue. If this condition is not overcome, a progressive dementia sets in, of which the special character is violence of temper, and a tendency to impulsive action. This dementia is generally complicated with maniacal attacks intervening at uncertain periods and marked by furor or violence. Dipsomania or insane drinking is a not very uncommon result, apart from all other indications of aberration. Progonosis is unfavorable.

III. Insanity associated with other Neuroses.—*Epileptic Insanity.*—In the intervals between the fits the patient is generally stupid and dull of apprehension. Immediately before or after fits, or, as some believe, occasionally taking their place, mania of a violent and furious, of a subacute, or of an ecstatic character presents itself. All authorities recognize epileptic insanity as the form most dangerous to the public. Prognosis is unfavorable. *Hysterical Insanity.*—The symptoms described in the article Hysteria may become so exacerbated as to amount to insanity. Superadded to these may be delusions of a sexual nature. The most extreme form of mental disturbance supervening on hysteria is acute mania of a very violent character; it is generally of a delirious nature, but does not usually continue for any great length of time. It is open to question whether the "fasting girls" and women with "stigmata" should not be included among the hysterically insane. Men, although very rarely, are liable to this form of insanity. In a sense the prognosis is favorable, inasmuch as prolonged treatment procures great abatement of symptoms, if not actual recovery. *Insanity occurring with locomotor ataxy* strongly resembles general paralysis. Taken over all, it may be stated that the symptoms differ more in degree than in kind, not being so intense. There is not the same extravagance of delusion or violence of mania.

IV. Insanity from the Presence of Adventitious Products is marked by progressive dementia of a dull heavy character and the absence of delusion. Prognosis is unfavorable.

V. Insanities associated with Morbid Conditions of the General System.—*Phthisical insanity* is stated to be characterized by a short period of mania, melancholia, or delusion, which soon passes into a mixture of subacute mania and dementia. The symptom, according to Clouston, is a tendency to be suspicious. (Consult Clouston, "Tuberculosis and Insanity," *Journ. of Mental Science*, April, 1863.) *Rheumatic insanity* is characterized by hallucinations of sight, touch, and taste, loss of memory, acute delirium succeeded by confusion of ideas and sluggishness of mind, accompanied by choreic movements of the limbs, deadening of reflex action, and even paralysis. These symptoms appear as the articular affection diminishes or disappears; they are, as it were, one vicarious of the other. Prognosis is favorable. (See Griesinger *On Mental Diseases*, p. 189; Clouston, *Journ. of Mental Science*, July, 1870; Sibson, in Reynold's *System of Medicine*, vol. iv. p. 286.) In *gouty insanity* the alternation of the joint and head symptoms is also well marked. The latter are general mania with delusions of suspicion. Prognosis favorable. (*Vide* Berthier, *Annales Medico-Psychologiques*, 1869. Sydenham also alludes to the condition.) *Syphilitic insanity* frequently commences with acutely maniacal symptoms, shortly followed by hypochondriasis of marked character, paralysis of energy, and rapid progressive dementia. Extravagant delusions often present themselves so strongly as to render the diagnosis between this condition and general paralysis difficult. Prognosis unfavorable. (The most important paper on this form of insanity is by Mickle, *Brit. and For. Medico-Chirurgical Review*, July and October, 1876.) In *anæmic insanity*, however produced, the general train of symptoms is violent mania of short continuance followed by melancholic dementia. Prognosis favorable.

VI. Insanities occurring at Evolutional Periods of Life.—*Insanity of pubescence and adolescence* is manifested by various trains of symptoms. Acute mania is on the whole the most common: it is characterized by motor restlessness; the patient walks, talks, smokes, drinks, must ever be on the move. Where self-abuse comes in as a factor, the sufferer is melancholic and suspicious, self-accusing. Dipsomania is a not unfrequent symptom. But whatever may be the general symptoms of these three sets of patients, they have one common symptom, a perversion or increase of the sexual instinct. Prognosis is favorable as regards the attack present, unfavorable as to the probability of recurrence. *Climacteric insanity*, which is nearly as common in men as in women, is marked by pretty constant symptoms of a melancholic character. Prognosis generally favorable. *Senile insanity* is symptomatized by dementia with frequent intercurrent attacks of mania. Prognosis unfavorable. The most frequent symptoms of the *insanity of pregnancy* are melancholy and moral perversion, the latter taking the form of dipsomania. *Puerperal insanity* shows itself during the first seventeen days after labor, and is of sudden incidence; the mental symptom is acute delirious mania. Prognosis is favorable in this, as in the insanity of pregnancy. (*Vide* J. Batty Tuke, "On Puerperal Insanity," *Edin. Med. Journ.*, May, 1865, and June, 1867.)

VII. Toxic Insanity.—*Insanity of alcoholism* in the acute form may be marked by acute mania of a transient nature, *mania a potu;* by melancholia, frequently accompanied by delusions and hallucinations of a frightful character; in the chronic, by a type of dementia frequently simulating general paralysis. Prognosis of the acute form favorable, in the chronic the reverse.

In employing the above classification it must be clearly borne in mind that the term of the symptom should, whenever possible, be appended to the pathogenetic term; thus, puerperal mania, climacteric melancholia, senile dementia, acute idiopathic mania, epileptic mania, etc. If the terms are combined, the nature of the disease and its general psychical characteristics are expressed in terse language.

It will be noted that no separate notice has been taken of such popular terms as homicidal or suicidal insanity. They in nowise indicate a class of the insane; they are symptoms common to many insanities, especially to epileptic, traumatic, puerperal, and idiopathic insanity, and as such must be regarded as incidents in a given case.

Terminations of Acquired Insanity.

Insanity terminates in recovery, in death, or in chronic mania or chronic dementia. Accurate statistics of the two first-named terminations are unattainable, as a large number of patients are treated at home; and asylum statistics do not therefore show the result overhead, only that of the more aggravated cases. The result of treatment in lunatic hospitals gives about 40 per cent., calculated on the admissions, which, however, include idiocy, chronic terminative insanity, and such acknowledged incurable forms of the disease as general paralysis. This figure does not of course represent the results of treatment of all the insanities, which, although there are no figures at command to support the assertion, may be fairly estimated at not less than 70 per cent., excluding idiocy. There is a general tendency of all insanities to shorten life; as already noted, some are in themselves fatal, or render their subjects less able to withstand disease. Asylum statistics show from 7 to 8 per cent. per annum as the average mortality calculated on the numbers resident.

It is needless to attempt a description of the various phases of chronic terminative dementia and mania. Delusion may continue, or the patient may become more or less sottish and degraded in habits; or, on the other hand, he may retain a considerable amount of mental power, still not sufficient to render him a responsible member of society. The great mass of the inmates of asylums belong to this class of lunatics, mostly harmless, yet precluded from mixing with the world as much for the convenience and safety of society as for their own benefit. A small proportion are detained on account of their liability to suffer from recurrence of attacks of insanity, although they are not actually insane during the intervals. To this condition foreign authorities have applied the term *folie circulaire*, and some have asserted that it is the characteristic of certain cases *ab initio*. It is mostly confined to persons strongly hereditarily predisposed. The term explains itself: after intervals of comparative sanity, the patient manifests symptoms which run their course through the prodromal, the acute, and the demented stages, on again to recovery, in manner similar to a recent case.

Treatment.

In speaking of the treatment of the insanities, it will simplify matters to eliminate, in the first place, those forms of the disease which are not amenable to remedial agents in the present state of medical knowledge. Medicine, whether hygienic or therapeutic, cannot touch general paralysis, the insanity produced by adventitious products, or senile insanity, except in the reduction of intensity of symptoms. Traumatic insanity is for the most part hopeless; it is probable that sufficient attention has not been directed to surgical measures in such cases.

In the insanities due to morbid conditions of the general system, in those associated with other neuroses, and in toxic insanity, the physician attacks the head symptoms through treatment of the causating factor. It is true that in these forms symptoms have to be attacked directly, but ultimate cure is to be looked for through treatment of the diathetic condition. It is rare, and then only in the earlier stages of the initial symptoms, that the progress of these diseases is cut short by therapeutic measures, inasmuch as they seldom come under the cognizance of the physician at that period. The exception to this statement is to be found in the case of puerperal insanity, where the patient is very generally under immediate medical supervision; in her case, therefore, the prodromal indications are often observed, and the disease arrested by the timely administration of drugs. But in the great mass of cases the last idea which occurs to the minds of friends is the possibility of impending insanity, and it is not till the disease has considerably advanced that the fact is recognized and the physician called in. When he has the opportunity of applying his art during the initial stages, he directs his attention to the procuring of sleep by means of opium and other narcotics, the bromides of potash and ammonium and chloral hydrate, and by rectifying the disorders of the digestive system. But when the disease has reached the congestive stage the treatment becomes for the most part expectant, as it does in analogous complaints of other systems. "Change of scene" is often adopted, and properly so in the very earliest stages; but when the disease is confirmed it is much more apt to aggravate the condition, fatigue and excitement only fanning the flame; it is much the same as if a man with a congested lung were asked to walk a mile uphill, in the hope that he would breathe more freely at the top. Till within the last few years treatment by bleeding, cupping, and blistering, shaving the head, and cold applications, was much in vogue. In asylums of the present day a shaved head is never seen. It was likewise the custom to administer large doses of sedatives. The system of treatment which now generally obtains is almost purely hygienic. Opiates are much less used, and are to be deprecated in those forms characterized by excitement; in idiopathic and climacteric melancholia, however, they often produce good results. General constitutional treatment is what is usually adopted. In such forms as idiopathic mania and melancholia, the mania of adolescence, puerperal mania, and climacteric melancholia, the disease, like many others, runs its course, not very materially affected by remedial agents apart from those applied to the maintenance of the system, and its cure is similarly dependent on rest and nursing. And the main question concerning treatment is, Where are these best to be obtained? In the case of the poor there is no alternative, even in comparatively mild cases, but to send the patient to an asylum. In the case of the rich it resolves itself very much into a question of convenience, for, with plenty of money at command, the physician can convert any house into an asylum. But under ordinary circumstances, when the patient is violent, noisy, suicidal, homicidal, or offensive to society, it becomes necessary to seclude him, both for the purposes of cure and for the safety and comfort of the family. Except amongst the very affluent, treatment at home is for the most part unsatisfactory; it is very generally tried, but breaks down under the constant strain to which the friends are subjected. In a well-ordered hospital for the insane there is every possible appliance for treatment, with trained nurses who are under constant supervision; and it therefore affords the best chance of recovery.

History.—The history of the treatment of insanity has been stated to be divisible into three epochs—the barbaric, the humane, and the remedial. But this does not take into account the very highly humane and probably highly remedial system of treatment which obtained in very ancient times. In Egypt the temples of Saturn, and in Greece the Asclepia, were resorted to by lunatics, and the treatment there adopted was identical in principle with that of the present day. The directions given by all the classical medical authors, and especially Hippocrates and Galen, are of the soundest character. How long their influence existed it is difficult to say, but in the Middle Ages, and up to the middle of the last century, little attention was paid to the care or cure of the insane. A small proportion were received into monastic houses or immured in common jails. In 1537 a house in Bishopsgate Street, London, fell into the possession of the corporation, and was appropriated for the reception of fifty lunatics. This, the first Bethlehem Hospital or Bedlam, was removed in 1675 to Moorfields, and in 1814 the present hospital in St. George's Fields was erected. St. Luke's was instituted in 1751. Bedlams or houses of detention for lunatics appear to have existed in other cities, but, with these exceptions, no provision was made for the insane, who were allowed to wander at large. There is good reason for believing that many were executed as criminals or witches. About 1750 the condition of the insane attracted some amount of public attention, and the incarceration in madhouses of a considerably larger number than formerly followed, not on account of any philanthropic sympathy with their condition, but as a measure demanded for the public safety and comfort. But this measure by no means brought about the termination of the barbaric period. The houses, misnamed asylums, were in the hands of private parties, under little or no supervision, and were in fact merely prisons of the very worst description. The unhappy inmates were immured in cells, chained to the walls, flogged, starved, and not unfrequently killed. It is almost impossible to believe that this condition of matters existed far on into the present century. According to Conolly, "there is clear proof of the continued existence of these abuses in 1827; and it cannot be denied that not a few of them survived in some public and private asylums in 1850." Matters were no better in France when Pinel was appointed in 1792 to the charge of the Bicêtre, the great hospital of Paris for male lunatics. In that establishment, and in the Salpetrière, the condition of the inmates was as degraded as in the British madhouses. This great philanthropist adopted the bold step of striking off the chains and other engines of restraint from those under his care. About the same time, the most gross abuses having been brought to light in connection with the management of the city of York asylum, William Tuke, a member of the Society of Friends, was mainly active in instituting the York Retreat for the care and cure of insane members of that sect. This real asylum was conducted on non-restraint principles. The names of Pinel and Tuke are indissolubly connected with the history of the humane treatment of the insane, and to their efforts must be ascribed the awakening not only of the public but of the medical profession to the true principles of management. It took, however, many years before the principles laid down by these men were universally adopted. In 1815 a committee of the House of Commons brought to light many gross abuses in Bethlehem Hospital, and it was not till 1836 that mechanical restraint was entirely abolished in an English public asylum.

This took place at Lincoln, where Dr. Gardiner Hill did away with all engines of restraint. Shortly afterwards Conolly adopted the same line of treatment at Hanwell, near London, and through the influence of his example and precept the measure extended over the whole of Great Britain. Experience has shown that, as restraint of all forms is abandoned, the management of lunatics becomes easier. Walled-in airing-courts, barred windows, and strong dark rooms have almost entirely disappeared, and in some Scotch asylums it is found practicable to discontinue the use of lock and key. It has been said that the type of insanity has changed within the last forty years; it would be more true to say that the type of treatment has changed. It is much less common nowadays to meet with those extremely violent forms of madness which entered into the descriptions of many authors. With the reduction of restraint a higher order of supervision on the part of attendants is demanded, and as they are trained to rely more and more on the moral influence they can exercise over their charges, and less on mechanical apparatus, the patient is not so apt to resent control, and therefore a greater calm and contentment pervades the atmosphere of our asylum wards. This has been mistaken for a change in the type of the disease.

Statistics.—The statistics of lunacy are merely of interest from a sociological point of view; for under that term are comprised all forms of insanity. It is needless to produce tables illustrative of the relative numbers of lunatics in the various countries of Europe, the systems of registration being so unequal in their working as to afford no trustworthy basis of comparison. Even in Great Britain, where the systems are more perfect than in any other country, the tables published in the Blue Books of the three countries can only be regarded as approximately correct, the difficulty of registering all cases of lunacy being insuperable.

On the 1st of January, 1880, according to the returns made to the offices of the Commissioners in Lunacy, the numbers of lunatics stood thus on the registers:—

	Males.	Females.	Total.
England and Wales........	32,164	39,027	71,191
Scotland..........................	4,541	5,083	9,624
Ireland............................	6,359	6,460	12,819
Grand total.................	43,064	50,570	93,634

These figures show the ratio of lunatics to 100,000 of the population to be 279 in England and Wales, 217 in Scotland, and 236 in Ireland.

The next table is of interest as bearing on the question of the alleged increase of lunacy as a disease. Similar returns are not available for Ireland.

Numbers of Lunatics on the 1st January of the Years 1858–80, inclusive, according to Returns made to the Offices of the Commissioners in Lunacy for England and Wales and Scotland.

	England and Wales.	Scotland.		England and Wales.	Scotland.
1858	....	5,823	1870	54,713	7,571
1859	36,762	6,072	1871	56,755	7,729
1860	38,058	6,273	1872	58,640	7,849
1861	39,647	6,327	1873	60,296	7,982
1862	41,129	6,398	1874	62,027	8,069
1863	43,118	6,386	1875	63,793	8,225
1864	44,795	6,422	1876	64,916	8,509
1865	45,950	6,533	1877	66,636	8,862
1866	47,648	6,710	1878	68,538	9,097
1867	49,086	6,860	1879	69,885	9,386
1868	51,000	7,055	1880	71,191	9,624
1869	52,177	7,310			

There is thus an increased ratio in England and Wales of lunatics to the population (which in 1859 was 19,686,701, and in 1880 was estimated at 25,480,000) of 186·7 per 100,000 as against 279·4, and in Scotland of 157 as against 217 per 100,000. The publication of these figures has naturally given rise to the question whether lunacy has actually become more prevalent during the last twenty years, whether there is real increase of the disease. There is a pretty general consent of all authorities that if there has been an increase it is but very slight, and that the apparent increase is due, first to the improved systems of registration instituted by the boards of lunacy, which have brought under their cognizance a mass of cases which were formerly neglected, "who would not have been dealt with as paupers in 1858, but who are now dealt with as such, so as to obtain for them the advantage of accommodation in pauper asylums." Secondly, a further and far more powerful reason is to be found in the increasing tendency among all classes, and especially among the poorer class, to recognize the less pronounced forms of mental disorder as being of the nature of insanity, and requiring to be dealt with as such. Thirdly, the grant of four shillings per week which in 1876 was made by parliament from imperial sources for the maintenance of pauper lunatics has induced parochial authorities to regard as lunatics a large number of weak-minded paupers, and to force them into asylums in order to obtain the benefit of the grant and to relieve the rates. These views receive support from the fact that the increase of private patients, *i.e.* patients who are provided for out of their own funds or those of the family, has advanced in a vastly smaller ratio. In their case the increase, small as it is, can be accounted for by the growing disinclination on the part of the community to tolerate irregularities of conduct due to mental disease, and the consequent relegation of its victims to asylums for the sake of family convenience. And again, careful inquiry has failed to show a proportional increase of admissions into asylums of such well-marked forms as general paralysis, puerperal mania, etc. The main cause of the registered increase of lunatics is thus to be sought for in improved registration, and parochial and family convenience. If there is an actual increase—and there is reason for believing that there is a slight actual increase—it is due to the tendency of the population to gravitate towards towns and cities, where the conditions of health are inferior to those of rural life, and where there is therefore a greater disposition to disease of all kinds.

Bibliography.—The following are systematic works:—Bucknill and Tuke, *Psychological Medicine*, 4th edition, 1879; Blandford, *Insanity and its Treatment*, 1877; Griesinger, *On Mental Diseases*, New Sydenham Society, 1867; Maudsley, *The Pathology of Mind*, 1879. Conolly, *On the Treatment of the Insane*, 1856, bears chiefly on asylum management. Every question connected with lunacy will be found discussed in the *Journal of Mental Science*, to the first twenty-four volumes of which a general index has been prepared by Dr. Fielding Blandford, 1879. The works of Pinel and Esquirol are well worthy of attention. Consult also Krafft-Ebing, *Lehrbuch der Psychiatrie*, Stuttgart, 1879, and Dr. Heinrich Schüle, *Handbuch der Geisteskrankheiten*, the latter being the sixteenth volume of Von Zeimssen's *Handbuch der speciellen Pathologie und Therapie*, Leipsic, 1878. (J. B. T.)

LAW.

The effect of insanity upon responsibility and civil capacity has been recognized at an early period in every system of law. In the Roman jurisprudence its consequences were very fully developed, and the provisions and terminology of that system have largely affected the subsequent legal treatment of the subject. Its leading principles were simple and well marked. The insane person having no intelligent will, and being thus incapable of consent or voluntary action, could acquire no right and incur no responsibility by his own acts; his person and property were placed after inquiry by the magistrate under the control of a *curator.* The different terms by which the insane were known, such as *demens*, *furiosus*, *fatuus*, although no doubt signifying different types of insanity, did not infer any difference of legal treatment. They were popular names which were used somewhat indifferently, but which all denoted the complete deprivation of reason. During the Middle Ages the insane were but little protected or regarded by law. Their legal acts were annulled, and their property placed under control, but little or no attempt was made to supervise their personal treatment. In England the wardship of idiots and lunatics, which was annexed before the reign of Edward II. to the king's prerogative, had regard chiefly to the control of their lands and estates, and was only gradually elaborated into the systematic control of their person and property now exercised in chancery. Those whose means were insignificant were left to the care of their relations or to charity. In criminal law the plea of insanity was unavailing except in extreme cases. About the beginning of this century a very considerable change commenced. The public attention was very strongly attracted to the miserable condition of the insane who were incarcerated in asylums without any efficient check or inspection; and at the same time the medical knowledge of insanity entered on a new phase. The possibility and advantages of a better treatment of insanity were illustrated by eminent physicians both in France and England; its physical origin became generally accepted; its mental phenomena were more carefully observed, and its relation was established to other mental conditions which had not hitherto been regarded as insane in the proper sense of the word. From this period we date the commencement of legislation such as that known in England as the Lunacy Acts, which aimed at the regulation and control of all constraint applied to the insane. And at the same time we find the commencement of a new state of matters in the courts. Hitherto, the criteria of insanity had been very rude, and the evidence was generally of a loose and popular character; but, whenever it was fully recognized that insanity was a disease with which physicians who had studied the subject were peculiarly conversant, expert evidence obtained increased importance, and from this time became prominent in every case. The newer medical views of insanity were thus brought into contact with the old narrow conception of the law courts, and a controversy arose in the field of criminal law which in England, at least, is not yet settled.

The fact of insanity may operate in law—(1) by excluding responsibility for crime; (2) by invalidating legal acts; (3) by affording ground for depriving the insane person by a legal process of the control of his person and property; or (4) by affording ground for putting him under restraint.

1. Responsibility for crime may be destroyed by insanity. The theory of the limitations under which this plea is recognized by English law is first clearly stated by Hale (*Pleas of the Crown*, i. c. 2) in these terms: "When there is no will to commit an offence there can be no transgression, and, because the choice of the will presupposes an act of the understanding, it follows that when there is a total defect of the understanding there is no free act of the will in the choice of things or actions." This doctrine was closely followed by the courts, and in the subsequent cases we find nothing admitted in defence short of a total defect of the understanding. In later times, however, frequent attempts were made on the part of the defence to break through this stringent rule, and in 1843 the case of Macnaughton, which resulted in an acquittal, attracted so much public attention, and seemed to cast so much doubt on the law as previously understood, that a series of questions were put by the House of Lords to the judges with the view of determining conclusively how the law really stood. These answers practically affirmed the old law. They decided that, in order to establish a defence on the ground of insanity, "it must be clearly proved that at the time of the committing of the act the party accused was laboring under such a defect of reason from disease of the mind as not to know the nature and quality of the act he was doing, or if he did know it he did not know that he was doing wrong." These answers are now the ruling authority both in England and Scotland, although there have been undoubtedly many instances in which the defence of insanity has been sustained either through the judge abstaining from pressing the law very strictly or from the jury taking a wider view of the case. Frequently, also, a more lenient view has practically been given effect to by the intervention of the home secretary, many of the most puzzling cases having been disposed of in this way. When the prisoner is unable to plead or has been acquitted on the ground of insanity, the jury are obliged to state whether they find the prisoner to be insane, and in that case he is ordered to be detained during her majesty's pleasure; and the home secretary has power to order him to be detained at such place as he may direct. Prisoners who become insane while in prison upon any form of legal process may also be removed by warrant of the home secretary to whatever asylum he thinks fit. All these are known technically as criminal lunatics, and an asylum has been provided for their detention at Broadmoor, from which they can only be discharged by warrant of the home secretary. (39 & 40 Geo. III. c. 94; 3 & 4 Vict. c. 54; 23 & 24 Vict. c. 65; 27 & 28 Vict. c. 29; 30 & 31 Vict. c. 12.)

The law thus clearly laid down by the courts has been strongly condemned by most medical authorities, who maintain that it is founded upon an ignorant and imperfect view of insanity. There can be no doubt that insanity does not wholly or even chiefly affect the will through the intellectual faculties. The disturbance of emotion and feeling is at least of equal consequence. We have cases where a criminal act seems to spring entirely from this source, and very many others where we have a complex of morbid intelligence and feeling which it is impossible to disentangle. In cases like those it is impossible by any analysis to separate the intellectual from the emotional phenomena, and to assess the amount of intelligence which, although morbid or defective, ought to be sufficient to restrain the equally morbid emotional condition. It seems clear that in judging of responsibility we ought to take the mental condition of the insane as a whole; and the present view of the law seems to have originated partly from ignorance of the more obscure phenomena of insanity, and partly from the metaphysical conception of a will whose freedom is only limited by its intelligence. It must, however, be remembered, on the other hand, that the courts have had serious difficulties to encounter. The views of insanity and consequent irresponsibility presented to them in medical evidence were often so vague that they seemed capable of indefinite extension, and there is no subject on which the experts have appeared so much at variance with each other. But these difficulties, however much they may call for the watchfulness of the courts, seem no sufficient ground for limiting the effect of insanity in relation to responsibility to the intellectual faculties. Such a limitation seems opposed, not merely to our present knowledge of insanity, but to the experience of ordinary psychology. These controversies are not confined to England. In the United States the law may generally be said to be the same as that of England, but, as the judges have been by no means so tightly bound down as the English judges have been by the opinions in Macnaughton's case, a considerable tendency has been shown in many (or indeed most) States to take a more liberal view of the question. In France the provision of the Code Napoléon, "il n'y a ni crime ni délit lorsque le prévenu était en état de démence," depends for its effect upon the interpretation given to the word *démence*, and for some time the tribunals were inclined to interpret it in such a manner as to make the law very much the same as that of England; but the view of the physicians is now generally prevalent. In Germany the matter is dealt with in a section (§ 51, *R. G. B.*) of the criminal code, which was the result of very careful discussion both by physicians and lawyers. It runs thus: "There is no criminal act when the actor at the time of the offence is in a state of unconsciousness or morbid disturbance of the mind, through which the free determination of his will is excluded."

2. In the case of all civil acts, the general rule is that capacity must be measured in relation to the act. The mere fact of insanity will not in itself make void a will, for example, if it appears that the testator had a fairly clear conception of the nature of his property and the objects of his bounty. But it is needless to say that the least appearance of insanity in the deed itself, or any appearance of fraud or undue persuasion on the part of any one, is immediately fatal to the deed. In

the case of contracts an additional element is knowledge of the insanity by the other party. When the contract was entered into *bona fide*, and the insanity of the one party was not known to the other, the contract may not be set aside unless the parties can be exactly restored to their previous condition.

3. Both the property and person of the insane may be placed under control by a legal process. In England this right was early annexed to the prerogative of the crown, and is even yet in consequence not exercised by the ordinary courts, but by the lord chancellor and such other judges as may be entrusted with it by the sign manual. The procedure is now governed by the Lunacy Regulation Acts (16 & 17 Vict. c. 70; 18 Vict. c. 13; 25 & 26 Vict. c. 86). The question of insanity is tried before one of the masters in lunacy, either with or without a jury, according to circumstances. The terms of the inquiry are—whether the party is of unsound mind and incapable of managing himself and his affairs; and on this being found his person and property are placed in charge of one or more persons called committees, whose administration is subject to the masters in lunacy, and through them to the chancellor. Persons thus found insane (technically known from the old form of procedure as lunatics so found by inquisition) are under the inspection of the board of chancery visitors, consisting of two medical men and a barrister, who are appointed to visit them at intervals. They are not subject to the provisions of the Lunacy Acts.

In Scotland the old procedure is by a brieve or writ from chancery, formerly tried before the judge ordinary and now before the lord president of the court of session. The nearest male agnate of twenty-five years of age is appointed tutor, but, latterly at least, is not entrusted with the personal custody, the court, if necessary, selecting some one for the purpose, generally the nearest cognate. The procedure by brieves is now becoming infrequent. More generally application is made to the court of sessions to appoint a *curator bonis* to take charge of the estate. This procedure is in many ways simpler and more convenient, especially in the numerous cases which are unopposed, as the court when they are satisfied that every person concerned has had due notice will grant the application on the certificate of two medical men. In America and on the Continent similar forms of procedure exist, which cannot be gone into in detail. In the United States the law is mostly, as is natural, derived from the English sources, but the procedure is regulated by statute in the different States. In many other countries, where the common law is based on Roman jurisprudence, the procedure seems to differ in many points from the English forms, but in substance the law on the subject has in nearly all countries reached very much the same results.

4. Insane persons (although not lunatics so found by inquisition) may be placed under personal restraint. At common law this power is limited to cases where the insane person is dangerous to himself or others, but in practice it used frequently to be exercised with little discretion and often with great barbarity. The care and restraint of the insane (other than that exercised by their friends and relatives in their own homes) is now strictly controlled by the Lunacy Acts (8 & 9 Vict. c. 100; 16 & 17 Vict. c. 96; 16 & 17 Vict. c. 97; 25 & 26 Vict. c. 111), the general nature of whose provisions may be thus briefly described. The chief supervision of the insane is vested in a body called the Commissioners of Lunacy. No insane person can be received for profit, or detained in any house or asylum except upon an order by a person who becomes responsible for his detention, accompanied by certificates of two qualified medical practitioners that he is insane, and a proper person to be taken charge of and detained under care and treatment. Every such case must at once be reported to the commissioners, who must also be informed of the patient's death, discharge, change of residence, and similar circumstances. Not more than one insane person can be received into a house unless a license has been previously obtained. In the metropolitan districts such licenses are granted after due examination by the commissioners, and in the provinces by the justices of peace in quarter sessions. Every house thus licensed, together with public hospitals and asylums (which are not under license), and every patient under private treatment, are subjected to a more or less frequent inspection by the commissioners, as well as by visitors appointed in their respective districts by the quarter sessions. The private licensed houses are under especially frequent inspection; their regulations and arrangements are subject to the approval of the commissioners, and especial precautions are taken that the patients shall have full opportunity of having their cases examined and of communicating with the commissioners. Patients may be discharged as cured, or on the direction of the person who ordered their detention, or on the order of the commissioners, all these modes of discharge, however, being guarded by various conditions. The order for detention of a lunatic may be given by any person having an interest in him, and he is liable in damages if there prove to have been no sufficient ground for the order, his position differing in this respect from that of the physicians and keeper of the asylum, who are only liable in the event of negligence or mala fides.

In Scotland the equivalent Acts are 20 & 21 Vict. c. 71, 25 & 26 Vict. c. 54, and 29 & 30 Vict. c. 51. The system is in its main features the same as that of England, the leading differences being that the Commissioners of Lunacy are the only licensing body, and that an order granted on application by the sheriff takes the place of the order by a private person.

The regulations applicable to pauper lunatics differ in some respects from the ordinary case. The provisions applicable to them are for the most part to be found in 16 & 17 Vict. c. 97, and in 20 & 21 Vict. c. 71.

The nature of the evidence, and the manner in which it is to be presented to the court, is an important question in every department of the legal treatment of insanity. In England the courts, although giving increasing prominence to expert evidence, have gone a good deal on the theory that the medical evidence is merely a part of the general evidence in the case. In most Continental countries, on the other hand, the whole evidence is presented in the shape of reports by medical men (in most instances officials) who have previously examined the case; and in this way every piece of evidence as to the state of mind of the insane person is commented on by an expert who is presumably better acquainted with its true import than an ordinary court or jury.

Literature.—The most recent book on the general law and procedure in insanity is *A Treatise on the Law and Practice of Lunacy*, by H. M. R. Pope (London, 1877); Archibald's *Statutes relating to Lunacy* (2d ed., London, 1877) contains the statutory law on all branches; Bertrand, *Loi sur les Aliénés* (Paris, 1872), presents a comparative view of English and foreign legislations. In forensic medicine the works of Taylor (*Medical Jurisprudence*, 2d ed., London, 1873) and of Wharton and Stillé (*A Treatise on Medical Jurisprudence*, Philadelphia, 1873) are probably the English authorities in most common use. See also Casper and Liman, *Practisches Handbuch der Gerichtlichen Medicin*, Berlin, 6th ed., 1876; Tardieu, *Étude médico-légale sur la Folie*, Paris, 1872; Legrand du Saulle, *La Folie devant les Tribunaux*, Paris, 1864; and especially Krafft-Ebing, *Lehrbuch der gerichtlichen Psychopathologie*, Stuttgart, 1875. INSCRIPTIONS.[1]

I. Cuneiform.

INSCRIPTIONS in characters sometimes termed cuneiform or wedge-shaped, sometimes arrow-headed, have been found throughout a large part of western Asia—in Persia and Babylonia, Assyria and Media, Armenia and Mesopotamia. Plate I. The names given to the characters are derived from their form, as some of them resemble the points of arrows, though most have the appearance of wedges, thicker at one end than at the other. This appearance is due to the fact that the characters were originally impressed upon moist clay by a metal stylus, and the form consequently assumed by them was subsequently imitated by the engraver upon stone and metal. The characters were primarily pictorial, but in course of time the outlines of the primitive pictures came to be alone preserved, while the nature of the writing materials caused curves to become angles, and rounded lines straight ones.

Varieties of Cuneiform Writing.—The original home of the cuneiform system of writing was either Elam or Babylonia, the inventors of the hieroglyphics in which it originated being the ancient Accadian population of Chaldea. It passed from the latter to a number of other nations, undergoing at the same time a variety of modifications. It was first borrowed by the Semitic settlers in Babylonia and Assyria, and from them it was handed on to the Turanian tribes of India, the Alarodians of ancient Armenia, and the Aryans of Persia, while the Turanian inhabitants of Elam or Susiania preserved the system as it had been in use among the Accadians of Chaldea.

In Babylonia, Assyria, Susiania, and Media the forms of the characters underwent several changes at successive periods, the tendency in each case being to simplify the characters by dropping superfluous wedges. In Babylonia we have to distinguish between the archaic, the linear, the hieratic, and the later forms of the characters. The archaic forms are principally found on bricks and cylinders of the Accadian epoch (before 2000 B. C.), and are the oldest forms of the characters of which we have contemporary specimens. The linear forms were in use at the same time, and are marked off from the archaic forms by being written in continuous lines instead of a series of wedges, and sometimes also by a closer resemblance to the original pictures from which they were derived. The hieratic forms were mainly employed between the overthrow of the Accadian power (about 1700 B. C.) and the 8th century B. C., more especially for contracts and similar documents. The later forms may be seen on the monuments of Nebuchadnezzar and his successors, a further modification of them being used for the Babylonian transcripts of the Persian cuneiform inscriptions. In Assyria also we may classify the characters as archaic, hieratic, and later (or Ninevite), though the forms they assumed in Assyria were not identical with those used in Babylonia which we have called by similar names. The hieratic forms were mainly employed in Assyria for ornamental or religious purposes, and may be compared with our own black letter. In Susiania the archaic forms of the characters lingered to the last, though in the northern part of the country simplified forms were in use. In Media a considerable difference may be observed between the peculiar forms of many characters in the older inscriptions of Mal-Amir and the forms borne by them in the Protomedic transcripts of the Persian monuments. The Armenian or Vannic characters were the same as those of Assyria, except that where one line or wedge had to be drawn across another, it was broken into two. But this was to prevent the stone from breaking at the point of section.

It will be noticed that the cuneiform characters were employed to express very different languages. The Accadian, like the allied dialects of Susiania and primitive Media, was agglutinative, and probably belonged to the Ural-Altaic family of speech; Assyrian and later Babylonian were Semitic; Persian was East Aryan; while the Armenian of Van seems to claim affinity with that Alarodian group of tongues of which Georgian may be regarded as the modern representative.

The Origin and Development of the Cuneiform System of Writing.—As already stated, the cuneiform characters were in their origin pictorial. In many cases it is possible to restore the primitive hieroglyphics or ideographs by the help of the archaic and linear Babylonian forms, and a fragment of a clay tablet has been discovered on which the pictorial originals of a few characters are given. In order to restore the primitive pictures, it is frequently necessary to turn a character upon its side, from which we may infer that the ideographs were once written vertically like Chinese. Thus , the ideograph of "an eye," is plainly a representation of the eye in a vertical position.

The primitive pictures denoted either objects or ideas, the latter being represented metaphorically by the picture of one or more objects. "Life," for example, was expressed by the picture of a growing flower, "a month" by placing the numeral xxx. within the circle of the sun, which symbolized the day. But the same picture might denote more than one idea or object. Thus the circle of the sun represented not only "the sun" and "the day," but also "light," "brilliance," and the like; and a pair of legs represented the ideas of "going," "walking," and "running." By combining two or more ideographs together, fresh ideas might be symbolized to an almost infinite extent; "drinking," for example, is denoted by placing the three drops which denoted water within the picture of the mouth, "language" by substituting the tongue for the three drops of water, and "a tear" by setting the ideograph of water before that of the eye.

Out of this early picture-writing there soon grew a syllabary. Accadian was an agglutinative language, which was already largely affected by phonetic decay, the result being that on the one hand the same word might be used indifferently for noun, verb, and adverb, as in English, while on the other hand the loss of final sounds had reduced a great part of the vocabulary to the condition of monosyllables. Ideographs consequently came to be associated with the sounds of the words which they primarily or most usually represented, and these words were mostly monosyllabic. Thus the ideograph of "month" (*itii*) was known as *id* or *it*, that of "going" (*dun*) as *du*, that of "drinking" as *nak*, that of a "tear" as *ir*.

But the same object or idea was frequently expressed by more than one name, while each of the ideas represented by a single sign was naturally denoted by a different word. Hence the same ideograph, or cha-

racter, as we may now term it, had varying pronunciations assigned to it according to its meaning and use; the ideograph of the "sun," for instance was called, not only *ut* or *ud* (for *utu*), but also *par* (for *para*), *tam*, *lakh*, and *khis*. Thus the ideographs, as soon as they came to appeal to the ear as well as to the eye, were necessarily polyphonous.

A further step in advance was now taken. An ideograph continued to represent the pronunciation of the word for which it originally stood even when it no longer represented the word itself; that is to say, the pronunciation of the word it denoted became attached to it as a mere phonetic value. This important innovation, which amounted to a change of the old picture-writing into a syllabary, must have taken place at an early period in its history. Though native proper names, which were always significant, could be written ideographically, it was necessary to find some other way of denoting foreign proper names, which had no meaning in Accadian. The pronouns, moreover, must have been a difficulty from the first, and the fact that these are invariably represented in Accadian, not by ideographs, but by characters used phonetically, indicates a very early date for the employment of the characters to represent syllabic sounds as well as ideas. This is borne out by the existence of several compound characters, in which the second element denotes only the pronunciation of the words for which they stand. The picture of a corpse, for example, had the phonetic value of *bat*, since *bat* meant "corpse" and "death" in Accadian; but, as *bat* also signified "a fortress," the ideograph of "corpse" was inserted within the ideograph of "enclosure," not because there was any relationship between the ideas of "death" and "fortress," but to indicate that the character which meant an enclosure was to be interpreted as signifying "a fortress," and to be pronounced *bat*. So, too, the usual word for "going" was *dun* or *du*; but there was another word *ara* or *ra* with the same meaning, and when the latter was intended to be read, the fact was pointed out by attaching the character which had the phonetic value of *ra* to the ideograph which expressed the idea of "going."

While the characters could thus be used as mere phonetic symbols, some few of them could be employed, on the other hand, for the language of the eye only. These were the determinative prefixes and affixes, such as the eight-rayed star, which represented a deity, or the shaded circle, which denoted a country or place. Their original use seems to have been to mark out those groups of characters which had to be read phonetically, and not as ideographs.

Like the lexicographers of China, the lexicographers of Accad attempted to classify and arrange the characters of their syllabary. Every character received a name of its own, so that literary works could be copied from dictation. A list of primary characters was first drawn up, each of which was named from the object it originally represented. The remaining characters were regarded as compounds, and divided into two classes. The first class consisted of characters which differed from the primary ones in having extra wedges, the second class of those that were really compounds. This classification of the syllabary must have been completed at a very remote date, since the analysis of many of the compound characters can only be explained by the forms they bear in archaic Babylonian, and in some cases even the archaic Babylonian forms are not sufficiently primitive. We may gather from this some idea of the epoch to which the invention of the cuneiform system of writing reaches back.

The Transmission of the Cuneiform Characters.—As far back as the second millennium B. C. Semitic tribes were in possession of a part of Chaldea. Duigi, the son and successor of the first Accadian monarch of whom we have contemporaneous record, has left us an inscription in which the cuneiform system of writing is adapted to the expression of a Semitic language. By the 17th century B. C. the Accadian language seems to have been wholly superseded by Semitic Babylonian and its northern dialect Assyrian. Along with other elements of civilization, the Semites received the cuneiform system of writing from their predecessors, and in the process of transmission the transformation of the old picture-writing into a syllabary was completed. The Accadian words represented by the characters when used as ideographs became phonetic values, and, since the same ideograph usually represented several different words, almost every character was polyphonous. It is true that some of these Accadian words, and even some of the phonetic values borne by the characters in Accadian, were rejected by the Semites, but on the other hand new phonetic values attached themselves to a few of the characters derived from the Semitic pronunciation of the latter when employed ideographically. For the Semites continued to use the characters on occasions ideographically as well as syllabically.

A greater extension was also given to the employment of determinative prefixes; the name of an individual, for instance, is always preceded by an upright wedge, the names of a country and a city by the ideographs which stand for these two ideas. The reader was assisted towards knowing when a character was used as an ideograph by the employment of phonetic complements, that is to say, characters which denoted the last syllable of the word intended to be read. Thus, when the ideograph , "to conquer," is followed by the syllable *ud*, we may infer that it must be pronounced *acsud*, "I conquered," or some other person of the past tense of the same verb.

The real difficulty the cuneiform syllabary offers to the decipherer is not the polyphony of the characters, but one which would not have been felt by the Assyrians themselves. Accadian and Assyrian phonology did not always agree, and in borrowing the Accadian system of writing the Assyrians had to adapt the sounds of their own language, as best they could, to the phonetic symbols of another. Consequently no distinction in writing is made between final *b* and *p*; *g*, *c*, and *k*; and *d*, *dh*, and *t*. *Teth* is inadequately represented sometimes by *d*, sometimes by *t*; and there is but one character for *za* (זא) and *tsa* (צא). No difference could be drawn between *u* and *yu*, and *i* and *yi*, while the representative of the consonantal *ayin* has to stand also for the diphthong *ê*.

The Assyrians continued to follow the example of the Babylonians in writing on clay, but they also made use of papyrus and stone. This literature on clay is very extensive, and embraces every branch of study known at the time. For an account of it see BABYLONIA, vol. iii. p. 157.

The learned court of Assur-bani-pal in the 7th century B. C. amused itself with essays in Accadian composition, the extinct language of primitive Babylonia standing in much the same relation to the Assyrians that Latin does to us. But literary Assyrian itself was fast becoming an artificial dialect. The Aramæan alphabet was introduced into Nineveh at least as early as the 8th century B. C., and though Nebuchadnezzar and his successors continued to employ the cuneiform syllabary, the conquest of Babylon by Cyrus was a blow from which the old mode of writing never recovered. The literary dialect and the characters in which it was inscribed were more and more disused, and finally disappeared altogether. Commercial tablets, however, dated in the reigns of the earlier Arsacid princes, have been found written in cuneiform, and if M. Oppert's identification is correct, a deed of sale, now in the Zurich museum, and written in cuneiform characters, is dated in the fifth year of Pacorus, the contemporary of Domitian.

The Assyrian syllabary was borrowed by the Armenians and Minnians of Lake Van in the reign of a certain king named Lutipri in the 9th century B. C.

The characters both in form and use are identical with those of Nineveh, except that the Armenians rejected the polyphony of the Assyrian syllabary, and with one or two exceptions used each sign with one phonetic value only.

After the occupation of Armenia by the Aryans, the use of the cuneiform character seems to have been discontinued, and no "Vannic" or Armenian cuneiform inscriptions are known to exist of later date than the 7th century B. C.

The example set by the Armenians seems to have been soon followed by their Turanian neighbors in Media. The earliest specimens of the so-called Protomedic (or Amardian) syllabary are to be found in the inscriptions of Mal-Amir and Sherif Khan. The syllabary of Nineveh appears to have been again the source from which the new script was borrowed. As among the Armenians, polyphony was rejected, a few ideographs only were used, and a selected number of characters employed. The Protomedic transcripts of the Persian inscriptions are written in this syllabary. In Susiania or Elam the archaic Babylonian form of cuneiform continued in use up to the last.

It was reserved for the Aryans of Persia to discover the ultimate capabilities of the cuneiform system of writing by reducing its characters to an alphabet of forty letters. These were divided into two classes, those with an adherent vowel *a*, and those which were followed by *u* and *i*. At the same time all superfluous wedges were thrown away, and the forms of the characters thus simplified as much as their pronunciation. Dr. Oppert has pointed out the principle upon which the formation of this new alphabet was carried out. Some one meaning was selected among those a character might bear when used as an ideograph, and this was rendered by its Persian equivalent. The initial sound of the latter was the alphabetic value henceforth represented by the character. Thus , "time of life," '*Zaya* in Persian, was contracted into  and made to represent '*z* (*a*, *u*). A few ideographs were retained along with the alphabetic characters. The Persian cuneiform alphabet, called "Assyrian letters" by Herodotus, seems to have been invented in the early part of the reign of Darius, and, being confined to monumental purposes, soon fell into disuse.

Possibly the reduction of the cuneiform syllabary into an alphabet was suggested by a previous acquaintance with alphabetic writing. In the Persian inscriptions the words are divided from one another by an oblique wedge. A similar division of words is found in one or two Assyrian inscriptions.

See Ménant, *Le Syllabaire Assyrien*, 1861–73; Sayce, *Lectures upon the Assyrian Language and Syllabary*, 1877.

(A. H. S.)

II. SEMITIC.

An account has already been given (see ALPHABET) of the derivation of the Phœnician alphabet from the hieratic alphabet of the Egyptian papyri of the middle empire. No early monuments written in it have as yet been found; the first known examples belong to a time when the alphabet had been widely spread and a literature had long existed. At this time we find the alphabet divided into two branches, the Phœnician and the Aramæan, the first being again subdivided into archaic and Sidonian. The last two are chiefly distinguished by the form of the ש, which is angular in the first and rounded in the second.

The earliest inscription in the Phœnician alphabet known to us is the stele of Mesha, king of Moab, found at Dhibân and belonging to the 9th century B. C. In this Mesha relates that after the death of Ahab his god Chemosh enabled him to shake off the yoke of Israel, to drive the Gadites out of Ataroth, and to fortify Kir-hareseth, Aroer, Horonaim, Dibon, and other places. The language of the inscription differs only dialectically from Hebrew.

To the same form of the alphabet belong most of the Phœnician inscriptions on the engraved gems brought of late years from Assyria and Babylonia, among which may be mentioned a cone with the image of a "golden calf" and the names Shemaiah and Azariah (לשמעיהו בן עזריהו). The Aramaic legends on the bilingual lion-weights of Nimrud, which date from the reign of Tiglath-Pileser II. (745–727 B. C.) downwards, also belong to the same form of the alphabet. With these inscriptions may be classed the Phœnician inscription on a bowl lately restored by M. Clermont Ganneau, which mentions a King Hiram, and had been brought with other merchandise from Phœnicia to Cyprus, where it was found. Of later date are the *graffiti* scratched on the legs of the colossi at Abu-Simbel in Nubia by Phœnician travellers or mercenaries.

The most important monument of the Sidonian period of the Phœnician alphabet is the sarcophagus of Eshmun'azar, son of Tabnith (? Tennes), "king of the Sidonians," which is probably of the 6th century B. C. It may, however, be later. The inscription upon it states that Eshmun'azar had restored the ruined temples of Sidon, and prays the gods to preserve to that city the possession of "Dor, Joppa, and the rich cornlands in the plain of Sharon." Other noteworthy monuments of the same period are the so-called "Second Sidonian Inscription," which records the installation of a subordinate "king of Sidon" by a "king of the Sidonians" of Phœnicia; the inscriptions from Citium in Cyprus of King Pumyathon and his father Melecyathon in the 4th century B. C., as well as the bilingual Phœnician-Greek and Phœnician-Cypriote inscriptions from the same islands, the Phœnician-Cypriote inscriptions of Melecyathon having furnished Mr. George Smith with the key to the Cypriote syllabary; together with six inscriptions from Athens and two from Malta; and the three inscriptions found by M. Renan at Umm'-el-Awâmid on the Phœnician coast.

The numerous dedicatory inscriptions found on the site of Carthage are written in what is termed the Punic development of the Sidonian alphabet; all apparently belong to the Greek period. The most important Punic inscription is the tariff of sacrifices found at Marseilles in 1845, an abridged edition of which was discovered on the site of Carthage by Mr. Davis in 1860. The regulations contained in it have a striking analogy to many of those of Leviticus. Its date, however, cannot be very early, since it makes no mention of human sacrifices. The Punic alphabet was the source of those of Numidia and Bœtica, where inscriptions have been found.

The series of Aramæan inscriptions begins with the dockets on Assyrian contract-tablets of the age of Tiglath-Pileser II. and his successors, when Nineveh and Carchemish became the chief centres of trade in western Asia. To the same period may be assigned an interesting gem from Babylonia inscribed בח עברירה לבקשח, as well as the cylinder of the eunuch Achadban, son of Gebrod, from Babylonia, and the cone of Hadrakiâ, son of Hurbad, from Nineveh. As already observed, the inscriptions on the Assyrian lion-weights, though in the archaic Phœnician form of the alphabet, are Aramaic in language. Passing over the engraved stones of the Achæmenian epoch, we may notice the famous bronze lion of Abydos, belonging probably to the 5th century B. C., on which an Aramaic legend is written. Of considerably later date is the inscription on an altar found by M. Mariette in the Serapeum, in characters which resemble those of the Aramæan papyri of Ptolemaic Egypt. The alphabet of the latter, however, is still more closely represented by certain funeral monuments found in Egypt with Aramæan inscriptions, the best known of which is the inscription of Carpentras, which records the death of a priestess of Osiris.

Starting from the 1st century B. C., the ruins of Palmyra and Taiba have furnished us with a large number of inscriptions in the Aramaic dialect of the locality. MM. de Vogüé and Waddington alone have discovered more than a hundred of them. Most of them are written in what may be termed uncial characters, but there are a few in a cursive hand. Among the persons mentioned in them is Odeinath (Odenatus), the husband of Zenobia. Palmyrene inscriptions have been met with in Africa and Rome, and a bilingual one (in Palmyrene and Latin) has lately been found at South Shields.

Professor Sachau has recently discovered two inscriptions in Old Syriac characters, one at Zebed, near Palmyra, accompanied by Greek and archaic Arabic transscripts, and the other among the early Christian tombs of Edessa.[1]

Passing over an Aramaic legend found by M. de Saulcy on a sarcophagus of the tombs of the kings at Jerusalem, and the coins of the kings of Edessa, we may notice the Mendaite inscription of twenty lines discovered in a tomb at Abu-Shadr in southern Babylonia, and first explained by Dietrich. It probably belongs to the 4th or 5th century. Inscriptions in Western Aramaic have been found in the Hauran. Among these is one on a tomb at Sueydeh, raised by Odeinath to his wife Hamrath in the time of Herod the Great, accompanied by a Greek transcript. Six other inscriptions of the same period come from the temple of Siah; one of them is dedicated to the god Katsiu, the Zeus Kasios of the Greeks.

The Hauran, more particularly the neighborhood of Bozra, has also yielded a number of Nabathean inscriptions, written in a sort of Aramaic running hand. Nabathean inscriptions have further been found at Umm' er-Russas in Moab, and at Petra, as well as on the coins of Aretas and other Nabathean princes. But they are specially numerous on the rocks of Sinai, where they were scratched by pilgrims in the 3d and 4th centuries of our era, and were first deciphered by Beer. They consist for the most part of proper names, preceded or followed by the word *shâlom*, "peace." The Aramaic dialect of these inscriptions is tinctured by Arabisms, among which may be mentioned the use of the article *el.* Two Nabathean inscriptions have been discovered at Pozzuoli, where, as we learn from the Acts, there was a Jewish colony.

The Nestorian Syrians carried their language and letters as far even as China. The celebrated inscription of Sigan-fu is written in good Estrangelo of the 8th century. A Hebrew inscription has also been found at Khaï-fong-fu.

Ancient Hebrew epigraphy is poorly represented. The earliest Hebrew inscriptions are three from Siloam, one of which is addressed to "Baal of the temple," a fragment found in the streets of Jerusalem by M. Vernes, and a boundary stone discovered by M. Ganneau near Gezer. The royal names on the pottery found near the foundations of Solomon's temple are not Hebrew, but Phœnician. The Maccabean period has left us several inscribed monuments and coins. The oldest are the epitaph of eight members of the priestly family of Hezir (1 Chr. xxiv. 15) on the Doric tomb of St. James at Jerusalem, the beginning of an inscription on a monument to the north-west of Jerusalem, and an inscription on the sarcophagus found by De Saulcy in the tomb of the kings, which probably belongs to a female relative of Helen, queen of Adiabene, in the 1st century of our era. Other early inscriptions have been copied in Galilee, especially in the synagogues of Kefr-Bereim as well as in the Jewish catacombs on the Via Portuensis at Rome. From the 10th century onwards the Jewish cemeteries in Spain, Italy, the south of France, Turkey, and Egypt enable us to trace the history of Hebrew writing up to the close of the Middle Ages; and Professor Ascoli has lately drawn attention to the inscriptions in the Jewish cemetery of Venosa, which enable us to fill up the gap that had previously existed between the memorials of the 10th century and those of the 4th. We must not forget also the exorcisms, written in a dialect allied to that of the Mishna on bronze bowls found at Babylon by Sir A. H. Layard, or the sepulchral inscriptions collected by Firkowitz in a Karaite cemetery of the Crimea, dated sometimes from the creation, sometimes from the capture of Samaria. The latter belong to the 9th and following centuries, though the discoverer falsified the dates of many of them in order to assign them to an earlier period (see Strack in the *Z. D. M. G.*, xxxiv. 1, 1880). Hebrew inscriptions in ancient characters have further been met with from Tiflis to Derbend.

Arabic epigraphy begins with the rise of Islam. Two systems of writing were used concomitantly, the Cufic or uncial, and the Neski or running hand, neither of which, however, can be derived from the other. The earliest inscriptions yet known are two sepulchral ones, the first of which has been published by Wetzstein, Waddington, and De Vogüé, while the other has lately been discovered by Sachau at Zebed. A Cufic inscription, dated 693 A. D., has been copied by De Vogüé, at Jerusalem, and the old cemetery near Assuan contains a large number of similar inscriptions, some of which, as deciphered by Count Amari, contain the names of the companions of the prophet. Unfortunately this cemetery has never been thoroughly examined. Mention may also be made of Cufic inscriptions at Bozra, in Sicily, and elsewhere. Inscriptions in Greek and Neski Arabic have been found at Damascus, Tiberias, and other places, one of which is dated 696 A. D., while others are even older.

Passing to the north, we find the rocks of the desert of Safa (south-east of Damascus) covered with graffiti written in peculiar characters which long defied decipherment. About six hundred and eighty of them have been copied. M. Halévy, however, has now succeeded in reading them (see *Journal Asiatique*, Jan.–Feb., 1877, and *Z. D. M. G.*, xxxii. 1, 1878), and showing that they are mostly the productions of Thamudite soldiers in the Roman army. The alphabet turns out to be intermediate between the Phœnician and the Himyaritic. The Himyaritic is the name usually given to the form of the Phœnician alphabet used in southern Arabia. Here a considerable number of pre-Islamitic inscriptions have been found, belonging partly to the kingdom of Sabâ, partly to that of Ma'n or the Mineans, where a dialect allied to that of Hadramaut was spoken. Many of them contain the names of kings, while most make us acquainted with various deities, among others 'Athtar, the equivalent of Ashtoreth. The Himyaritic alphabet was carried to Abyssinia, where it became the Ghe'ez or Ethiopic syllabary. The earliest specimens of Ethiopic writing are two inscriptions of King Tazêna copied by Rüppell on the monuments of Axum, which belong to the 5th century.

Inscriptions in still undeciphered characters, some of which resemble those of the Himyaritic alphabet, though the larger number is more closely related to the demotic and hieratic characters of Egypt, have been copied (in 1880) by Professor Robertson Smith on the rocks of Taif near Jeddah. (Compare the inscription from the neighborhood of El-Wijh given by Wellsted, ii. 189.) Captain Burton has also found an inscription in characters not unlike the Himyaritic, in the Wady Intaysh, with which he compares two semi-Nabathean inscriptions from Wady Unayyid copied by Dr. Wallin, and an inscription at Mecca given by Dozy (*The Gold Mines of Midian*, 1878).

The inscriptions of the Semitic Babylonians and Assyrians are separately treated above. The curious Hittite hieroglyphics found of late years at Carchemish,

---

[1] The inscription at Zebed was first noticed by Dr. Bischoff. The letters seem to be derived from an Aramaic alphabet. Some of them resemble the enigmatical characters on gems from Diarbekir and the neighboring district, published by Dr. Mordtmann in the *Z. D. M. G.*, xxxi. 4 (1877).

Aleppo, Hamath, and various places in Asia Minor do not seem to conceal a Semitic language.

See Fr. Lenormant, *Essai sur la Propagation de l'Alphabet phénicien dans l'ancien Monde*, 1872–75; E. Renan, *Histoire générale et Système comparé des Langues Sémitiques*, 1863; Gesenius, *Scripturæ Linguæque Phœniciæ Monumenta*, 1837; Schröder, *Die phönizische Sprache*, 1869; De Vogué, *Mélanges d'Archéologie orientale*, 1868. Clermont-Ganneau's work on the *Moabite Stone* will supersede previous monographs.

(A. H. S.)

III. INDIAN.

The inscriptions of India are very numerous and of great variety. They are found upon rocks, pillars, and buildings, in caves, topes, and temples, and on plates of copper. These last are grants of land made by kings for religious purposes, and they are historically valuable because they contain, not only the name of the grantor, but a more or less complete list of his predecessors. Implicit reliance cannot be placed on these documents. Vanity has sometimes led to the invention of an illustrious ancestry. So far back as the old lawgiver Manu, punishments were denounced upon the forgers of grants, and plates that are palpable forgeries have been discovered.

The oldest and most important of the inscriptions are the religious edicts of King Piyadasi, who is styled *Devánam-piya*, "the beloved of the gods." Their date is clearly proved to be about 250 B. C. This Piyadasi is now by universal consent admitted to be identical with the great Maurya king Asoka, grandson of Chandra-gupta, whose identification by Sir. W. Jones with Sandrakoptos or Sandracottus, the ally of Seleucus Nicator, is the corner-stone of that very tottering structure, Hindu chronology. The first published inscription of Piyadasi was copied from a stone column 42 feet high, and known as the *Lát* or pillar of Fíroz Sháh, a sultan who, about the middle of the 14th century, conveyed it to Delhi from a village in the hills about 250 miles distant, and re-erected it as an ornament to his capital. The same monarch brought from Meerut and re-erected near his palace another similar column, but this was thrown down by an explosion in the year 1719, and, although it has lately been raised again, it is so much mutilated that scarcely half of the inscription remains. A copy of the inscription on the first of these columns was published by Captain Hoare in the *Asiatic Researches* in 1801. It was a subject of great curiosity and speculation, but it baffled all attempts to decipher it until the year 1837, when the acute sagacity of James Prinsep surmounted the difficulty.[1] This particular alphabet having been first discovered on and translated from a *Lát*, or pillar inscription, obtained the name of the "*Lát* alphabet," but the name "Indian Páli" is now generally preferred.

The mystery of the alphabet being thus penetrated, the longer and more important rock inscriptions were taken in hand. Two versions were then known, one at Girnár in Káthiáwár, the other discovered and copied by Kittoe at Dhauli in Orissa, at the extreme opposite side of India. Dr. Wilson of Bombay and Captain Postans furnished Prinsep with copies of the former, and he collated the two versions. He then transliterated them in modern characters, and with the help of a pandit he rendered them into English. Not long afterwards Prinsep's brilliant discoveries were brought to a close by his untimely death in April, 1840.

In the year 1836 M. Court, an officer in the service of Ranjít Singh, the ruler of the Punjab, made known the existence of a rock inscription at Kapur-di-giri, west of the Indus, and not very far from Attock. Subsequent explorations show that the rock is really situated in the village of Sháhbáz-garhi. No copy was obtained until October, 1838, when the traveller Masson most carefully and perseveringly made a calico stampage and an eye copy. These he presented to the Royal Asiatic Society, whose acute and laborious secretary, Edwin Norris, proceeded to make a reduced copy of the calico stampage. This inscription was not in the Lát character, but in that now known as the Bactrian Páli or Ariano-Páli, which bears strong indications of a Phœnician origin. The Lát alphabet or Indian Páli is written, like the character of the Sanskrit, from left to right; the Ariano-Páli runs from right to left. This character had previously been found on the bilingual coins of the Greek kings of Bactria, the obverse of which bore a Greek legend, and the reverse had some letters which proved to be a rendering of the same in Ariano-Páli. Masson first detected the connection between the two legends, and Prinsep following up his suggestion soon settled the value of several of the Ariano-Páli letters. Similar discoveries were made simultaneously by Lassen in Germany. The letters so discovered were available as keys for the interpretation of the Sháhbáz-garhi inscription, but only as keys, for the inscription contained many dubious and unknown characters, and, unlike the alphabet of the Indian Páli, it possessed numerous compound letters. It was in the process of copying that Norris, like Prinsep, hit upon a clue. He remarked a frequently repeated group of letters, and he came to the conviction that these represented the words *Devánam-piya*. He made known this opinion (*J. R. A. S.*, viii. 303), and gave a copy of a short separate part of the inscription to a young student, afterwards Professor Dowson, who accepted the reading. Knowing that these words were the oft repeated title of Piyadasi in the Girnár inscription, Mr. Dowson proceeded to make a comparison of the two and discovered their identity. The whole inscription eventually proved to be a third version of Asoka's edicts. In the year 1850 a fourth version was discovered and copied, though it was not made public, by Mr. (now Sir Walter) Elliot, at Jaugada near Ganjam in Orissa, about 50 miles south of Dhauli. Lastly, a fifth copy was discovered by Mr. Forrest early in 1860, at Khálsí, west of the Jumna, about 15 miles from Masúrí or Mussooree. The late Captain Chapman (*J. R. A. S.*, xiii. 176) brought from Ceylon a copy of a small fragment of rock inscription, and in this the words Devánam-piya are distinct, but the copy was made by eye and is unintelligible. These inscriptions show the extent of Asoka's influence, if not of his direct empire. Their positions are Afghánistán, the foot of the Himálayas, the extreme east and west of the centre of India, and presumptively Ceylon, where it is known from other sources that Asoka ruled. The inscription of Sháhbáz-garhi is the only one in the Ariano-Páli character, the others are in the Lát or Indian Páli alphabet. The language of all of them is a Prákrit or a sort of Páli, the immediate descendant of Sanskrit, but bearing marks of a long process of detrition. There are dialectical differences in the different versions, and there are also divergences of spelling, as *lája*=*rája*, *dipi*=*lipi*, etc. The Khálsí inscription differs from the other Indian Páli versions in having two of the three distinct sibilants of the Sanskrit, while the others have only one. The inscriptions at Girnár, Khálsí, and Sháhbáz-garhi consist of fourteen distinct edicts; those at Dhauli and Jaugada omit three of them, but add two new ones, which, being written apart, are known as the "detached edicts."

When Prinsep and his pandit made their translations they had before them only the two versions of Girnár and Dhauli. On the publication of the Sháhbáz-garhi version Professor H. H. Wilson made a comparison of the three, and brought out an amended translation which was certainly an improvement upon Prinsep's; but he was far from satisfied with his performance, and declared it "open to correction on every page." The learned and critical Burnouf subsequently studied them, and made fresh translations of parts, which again marked an advance, but he declared that "personne ne peut se flatter d'arriver du premier coup à l'intelligence définitive de ces monumens difficiles." Professor Kern of Leyden has since worked upon them, and his method is turning the language back into Sanskrit and then translating into English. This process only carries out more systematically that of the previous translators. They all interpreted the inscriptions through Sanskrit, making use of such knowledge of Páli and the other Prákrits as they possessed or could acquire. The translations are acknowledged to be imperfect and unsatisfactory, and no great improvement can be expected through Sanskrit alone. The words vary greatly in form from their Sanskrit originals, and some changes of meaning and construction no doubt accompanied their alterations in form. Comparative philology, in tracing back the modern tongues of India through the Prákrits to the Sanskrit, will probably throw fresh light upon the language of the inscriptions, and make more perfect translations possible. All the known inscriptions of Asoka are now accessible to the student. General Cunningham, the Archæological Surveyor of Hindustan, has published the first volume of his *Corpus Inscriptionum Indicarum*, in which he has given carefully corrected facsimiles, with parallel transliterations, of the five versions and all published translations. Mr. Burgess also has published an excellent collotype of the Girnár version, with transcriptions and translations, in his *Archæological Survey of Káthiáwár.* Asoka was a convert to Buddhism, but his edicts bear few distinctive marks of that or any formal religion, and they are entirely free from vaunts of his power and dignity. They inculcate a life of morality and temperance, a practical religion, not one of rites and ceremonies. They proscribe the slaughter of animals, and they enjoin obedience to parents, affection for children, friends, and dependants, reverence for elders, Buddhist devotees, and Brahmans, universal benevolence, and unreserved toleration. They would seem to have been set up at a time when there were few differences between Buddhists and Brahmans, and their apparent object was to unite the people in a bond of peace by a religion of morality and charity free from dogma and ritual. One of the edicts provides for the appointment of missionaries to spread the religion. The thirteenth edict refers to Asoka's foreign relations. It mentions the Greek king Antiochus, and refers to some connection through him with four other kings, Ptolemy, Antigonus, Magas, and Alexander, or, to quote the words of the Sháhbázgarhi version, "Antiyoke nama Yona-raja parancha tena Antiyokena chaturo |||| rajane Turamaye nama Antikini nama Maka nama Alikasandare nama." The four strokes are numerals, equivalents of the word *chaturo* (four), and in the Khálsí version the numerical sign used is +. Prinsep and his pandit gave a confused rendering of this edict, but no one else has attempted to translate it. There has been some difference of opinion as to the identification of these Greek kings, but the most approved names are Antiochus Theos of Syria, Ptolemy II. of Egypt, Antigonus of Macedonia, Magas of Cyrene, and Alexander II. of Epirus, 253–251 B. C.

---

[1] He found the key to it by a very happy guess. He was engaged in copying some short inscriptions engraven upon the pillars of a temple at Sánchi, and he observed that, although each inscription was in the main different, all of them terminated with the same two letters. Knowing that devout Buddhists were in the habit of making votive offerings of pillars, rails, and ornaments to their temples, and of inscribing upon them a record of the gift with the name of the donor, Mr. Prinsep assumed that the oft repeated two letters represented the word *dánam*, "gift," and this surmise proved to be correct. He thus obtained the consonants *d* and *n*, and as the name preceding the word *dánam* must necessarily be in the genitive case, this fact made him master of the letter *s*. He used this key with such ardor and success that in the course of a month he was able to make a transliteration and translation of the whole inscription.

Besides the five great inscriptions of Asoka, there are six other rock inscriptions consisting of single edicts, three of which, found at Sahsarám, Rúpnáth, and Bairát are the same, but the last is imperfect. Dr. G. Bühler has translated them. A second and different inscription at Bairát has been translated by Wilson, Burnouf, and Kern. These separate edicts are not found among the fourteen, but they are of similar style and spirit. Two of them have the distinction of being dated thus: "256 [years have elapsed] since the departure of the Teacher," *i. e.*, since the death of Buddha, the time of which has been variously assigned to 544 and 478 B. C. In these two edicts Asoka, after stating that he had been "a hearer of the law" more than thirty-two years and a half, adds, "I did not exert myself strenuously. But it is a year and more that I have entered the community of [ascetics]."

The pillars erected by Asoka would appear to have been numerous, but only a few now remain. Six of these, at Delhi (2), Alláhábád, Lauriya (2), and Sánchi, are inscribed. Five of them present in a slightly variant form the text of a series of six edicts that were promulgated by Asoka in the twenty-seventh year of his reign, 236 B. C. These pillar inscriptions, which are beautifully cut, are not repetitions of those on the rocks, but they are of similar purport. The pillars at Delhi and Alláhábád have since been covered, wherever space was left, and even between the lines of Asoka's inscription, with records and scribblings of later dates. The only one of consequence is the inscription of Samudra-gupta on the Alláhábád pillar. The "iron pillar" of Delhi belongs to a later age, and its inscription is dated 1052 A. D.

In immediate succession to the rock and pillar inscriptions of Asoka come the inscriptions of the caves and rock-cut temples. There are caves in Bihár, Cuttack, and elsewhere with inscriptions showing that they were constructed by Piyadasi or Asoka. Soon after these, about the 2d century A. D., come the caves at Khandagiri in Cuttack, over which there is an important but much defaced inscription. It records the construction of the caves by a king Aira of Kalinga, a convert from Brahmanism to Buddhism, and it gives glimpses of his religious and beneficent life that make its defacement a matter of especial regret.[1] The letters of the inscriptions in the oldest caves show a slight departure from the forms of the Lát alphabet, and would seem to have been written from about the beginning of the Christian era to the 5th century. The caves at Ajanta, Karlen, Kanhari, Násik, and Junír are Buddhist, and contain many inscriptions, but most of these records are of no historical value, as they simply commemorate the dedication of a cave, chamber, cistern, or some other votive gift, coupled with the name of the donor. The same observation applies generally to the topes at Amarávati, Sánchi, and elsewhere. In the caves at Násik there are some historical records, and the great cave-temple of Karlen is recorded to have been constructed for an emperor named Devabhúti, by a foreigner called "Dhanukákatá" or "Dhínukakati," which name is understood to represent Xenocrates. In a Jain cave-temple at Bádámi there is an inscription of the Chálukya dynasty, dated in 578 A. D. The caves of Elephanta and Ellora are of a much later date. There have been many explorers of the caves and copyists of the inscriptions. Dr. J. Wilson successfully interpreted some of the inscriptions, but Dr. Stevenson has been the greatest decipherer. The letters of the inscriptions in the caves are often formed with a want of precision and distinctness, and the copies obtained are not always satisfactory, so the translations are open to some doubt, and are capable of improvement.

Soon after the inscriptions of Asoka we have those of the Turushka or Indo-Scythic kings Kanishka and Huvishka, the Kanerke and Ooerke of the bilingual coins, whose names are linked with a third as "Hushka, Jushka, and Kanishka" in the Kashmir chronicle called Rája Taranginí. Their inscriptions have been found in Afghánistán, in the Punjab, and in the hills, and as far east as Mathurá. With the exception of those at Mathurá, they are in the Ariano-Páli character. They are all short; some consist of only six or seven words. The majority of the inscriptions are dated. The Macedonian months are used, but there is no certainty as to the era. The word used is "Samvatsara," and, as there is an era so called, some maintain that they are dated in that era, but as the word "samvatsara" means also year, it may imply a year of some unknown era or of a king's reign. Their period is about the beginning of the Christian era. The first inscription discovered was on a stone slab found by General Court in a large tope at Manikyála in the Punjab; the longest is one punched on a brass vase extracted by Masson from a tope at Wardak in Afghánistán. The former was discovered just before Prinsep's death, but he did no more with it than picking out the king's name as "Kaneshm," and conjecturing that the date figured xx7 signified cxx. General Cunningham subsequently interpreted the date as 446, and the title of the king correctly as "Kanishka, maharaja of the Gushang tribe." No further discoveries of importance were made until the year 1862, when Mr. Roberts obtained, at Hasan Abdál in the Punjab, a copper plate with five lines of inscription, which he sent to the Royal Asiatic Society. The letters on this plate were clearly written, and, when read by Professor Dowson, the record furnished the long desired key to the numeral system, for the date was given both in words and figures. The forms of the numerals had made Prinsep and others suspect a Roman influence, but the figure 7 proved to be 10 and the x equivalent to 4. The inscription was a record made by a satrap named Liako Kusuluko of his having deposited a relic of Sákyamuni (Buddha) in an institution near Taxila. Before the publication of the translation copies of this inscription were sent to India with the explanation of the date, and with a call for independent translations of the text. General Cunningham made a translation which was revised by Bábú Rájendra Lál, and when brought together the versions were found to be in close agreement.

---

[1] Bábú Rájendra Lál in vol. ii. of his *Antiquities of Orissa*, just published, has proposed some emendations of a few lines of Prinsep's version, but the rock is now in a worse condition than it was in Prinsep's time, and a full translation is hopeless.

Professor Dowson succeeded in making out considerable portions of the Manikyála, Wardak, and other inscriptions, and found that all had reference to the deposit of relics. No progress has since been made in the interpretation of these inscriptions, although there is ample scope for further study. The Manikyála inscription is dated in the year 18, and was made in the reign of Kanishka; the Wardak urn is dated in the year 51, and was inscribed in the reign of his successor Huvishka. There are other inscriptions, in which the names of these kings appear, and the names of King Moga or Moa and of Gondophares have also been found. Several short inscriptions in this character owe their discovery to General Cunningham, who has been most persevering in his search and constant in his endeavors to interpret them. Another series of inscriptions of these Indo-Scythian rulers was obtained by General Cunningham from the ruins of the Buddhist temples and other buildings at old Mathurá. These inscriptions are in the Indian Páli character and the Sanskrit language, and have been translated by Professor Dowson. Several of them are dated "*Sam*," the common abbreviated form of Samvatsara. The earliest certain date is 44, and as one of the dates is as high as 280, it is clear that some era is intended. If it be the Samvatsara era, the dates range from 13 B. C. to 337 A. D. These inscriptions have two peculiarities in which they agree with the practice of the inscriptions in western India; instead of months they use the triple series of seasons, and the numerals are arbitrary symbols having little or no arithmetical relation to each other. The explanation of these figures has occupied the attention of Prinsep, Dr. Stevenson, General Cunningham, Dr. Bhau Dáji, and Mr. E. Thomas, and may be said to be accomplished. Some further inscriptions have since been found at Mathurá and translated by General Cunningham. The whole series furnishes the names of Kanishka, Huvishka, and Vásudeva [BAZOΔHO of the coins], all of whom bear the arrogant title *Devaputra*, "son of God." One of the last discovered inscriptions is dated as early as the year 5.

About the period of the Indo-Scythians there was in Suráshtra, on the western coast of India, a dynasty of rulers who called themselves Kshatrapas or satraps, and are known as the Sáh or more properly Sinha kings. These have left some inscriptions commencing with their founder Nahapána, but they are better represented by their coins, the legends on which are in the Indian Páli character. On some of the earlier ones the distinctive name of the king is given also in Ariano-Páli. An inscription in a cave at Násik records its construction and dedication by Nahapána. The most important of their inscriptions is that of Rudra Dáma, the seventh king of the dynasty, dated in the year 72, but of what era is undetermined. This is engraven on the famous rock of Girnár near Junágarh, the same as that on which the edicts of Piyadasi are inscribed. It is in Indian Páli, and was first deciphered by Prinsep. Since then the translation has been revised by Professor Wilson, Dr. Bhau Dáji, and Professor Eggeling. It commemorates the repair of a dam or embankment of the river Palásiní. Its most interesting passage records the fact that the same dam had been formerly repaired by "the Maurya rája Chandragupta," the classical Sandrakoptos, and it is the only monumental mention known of that king. It also names Asoka specifically as "Asoka Maurya," not as Piyadasi. Mr. Burgess has published a fine collotype of this inscription in his *Archæological Survey*.

After the Sáhs come the Guptas of Kanauj, a dynasty which must not be confounded with the Maurya dynasty of which Chandragupta (Sandrakoptos) was a member. The inscriptions of the Guptas are in a slightly advanced form of the Indian Páli. One, the first known, translated by Dr. Mill, was inscribed by Samudra-Gupta on the old Asoka column at Alláhábád, another is inscribed on the Asoka rock at Girnár, being the third on that rock. It records another repair of the Palásiní dam by Skanda-Gupta, and a copy with a translation by Bhau Dáji is published in Burgess's *Survey*. All the Gupta inscriptions are dated in the *Gupta-kála*, the Gupta era, the epoch of which has long been and still remains a subject of dispute. Other inscriptions of this dynasty have been found at Mathurá, on a pillar at Bhitarí in Gházípúr, at Sánchi, Eran, and other places. After the Guptas come the inscriptions of Toramána, who seems to have succeeded them in Central India.

The Guptas were overthrown by the Vallabhi or Ballabhi kings, the founders of Vallabhi-pura in Káthiáwár, who established themselves in the latter half of the 5th century A. D. No monumental inscriptions of this dynasty have been discovered, but their copper grants are numerous, and fresh discoveries are constantly being made. Far down in the south the Kongu kings have left grants of the 4th century, and one of questionable authenticity corresponds in date to 188 A. D. In the Deccan reigned the great family of the Chálukyas, which in course of time divided into two branches. They reigned from the 5th to the 12th century A. D., and their inscriptions, especially their copper grants, are very numerous. Sir Walter Elliott made the history of this dynasty his especial pursuit, and succeeded in collecting and epitomizing some hundreds of inscriptions. Mr. Burgess, the archæological surveyor of western India, and other explorers are constantly making fresh discoveries of inscriptions relating to the Chálukyas and other dynasties of the west and south; and these are quickly translated by the indefatigable Mr. Fleet, Mr. Rice, Dr. Burnell, and other busy translators. Many other dynasties have left copper plate inscriptions which cannot be here described, and a mere list would be of greater length than value. The inscriptions are found in all parts of the country, and date from the early periods above stated until the establishment of the Mahometan rule. They are almost all in Sanskrit, but in the south inscriptions are found in Tamil and Old Canarese. Through all of them the gradual change of the letters from the old Indian Páli to the modern forms is distinctly traceable. Mr. Rice has published a thick volume of inscriptions discovered in Mysore, and the pages of the *Indian Antiquary* add every month to the store. A very handsome volume of photographs of inscriptions has been prepared by Mr. Fleet at the expense of the government, but only ten copies have been made.

The inscriptions of the Mahometans in India are also numerous. They are either in Arabic or in Persian, and are often engraved with exquisite skill and grace. Some celebrate victories, but most of them record the erection of mosques, palaces, tombs, and other edifices. These inscriptions are occasionally valuable in settling dates, but as the Mahometans are good historians their inscriptions are of less importance than those of their Hindu predecessors, who did not write history. (J. D.*)

IV. GREEK.

Greek inscriptions.

Etymologically the term inscription (*ἐπιγραφή*) would include much more than is commonly meant by it. It would include words engraved on rings, or stamped on coins,[1] vases, lamps, wine-jar handles,[2] etc. But Boeckh was clearly right in excluding this *varia supellex* from his *Corpus Inscriptionum Græcarum*, or only admitting it by way of appendix. Giving the term inscription a somewhat narrower sense, we still include within it a vast store of documents of the greatest value to the student of Greek civilization. It happens, moreover, that Greek inscriptions yield the historian a richer harvest than those of Rome. Partly from fashion, but partly from the greater abundance of the material, the Romans engraved their public documents (treaties, laws, etc.) to a large extent on bronze. These bronze tablets, chiefly set up in the Capitol, were melted in the various conflagrations, or were carried off to feed the mint of the conqueror. In Greece, on the contrary, the mountains everywhere afforded an inexhaustible supply of marble, and made it the natural material for inscriptions. Some Greek inscribed tablets of bronze have come down to us,[3] and many more must have perished in the sack of cities and burning of temples. A few inscriptions on small thin plates of lead, rolled up, have survived; these are chiefly imprecations on enemies[4] or questions asked of oracles.[5] But as a rule the material employed was marble. These marble monuments are often found *in situ;* and, though more often they were used up as convenient stones for building purposes, yet they have thus survived in a more or less perfect condition.[6]

Materials for them.

Place of erection.

Inscriptions were usually set up in temples, theatres, at the side of streets and roads, in *τεμένη* or temple-precincts, and near public buildings generally. At Delphi and Olympia were immense numbers of inscriptions,—not only those engraved upon the gifts of victorious kings and cities, but also many of a more public character. At Delphi were inscribed the decrees of the Amphictyonic assembly, at Olympia international documents concerning the Peloponnesian cities; the Parthenon and Acropolis were crowded with treaties, laws, and decrees concerning the Athenian confederation; the Heræum at Samos, the Artemisium at Ephesus, and indeed every important sanctuary, abounded with inscriptions. It is a common thing for decrees (*ψηφίσματα*) to contain a clause specifying where they are to be set up, and what department of the state is to defray the cost of inscribing and erecting them. Sometimes duplicates are ordered to be set up in various places; and, in cases of treaties, arbitrations, and other international documents, copies were always set up by each city concerned. Accordingly documents like the *Marmor Ancyranum* and the *Edict of Diocletian* have been restored by a comparison of the various fragments of copies set up in diverse quarters of the empire.

Forms of inscribed marbles.

Greek inscribed marbles varied considerably in their external appearance. The usual form was the *στήλη*, the normal type of which was a plain slab, from 3 to 4 or even 5 feet high,[7] 3 or 4 inches thick, tapering slightly upwards from about 2 feet wide at bottom to about 18 inches at the top, where it was either left plain or often had a slight moulding, or still more commonly was adorned with a more or less elaborate pediment; the slab was otherwise usually plain. Another form was the *βωμός* or altar, sometimes square, oftener circular, and varying widely in size. Tombstones were either *στῆλαι* (often enriched beneath the pediment with simple groups in relief, commemorative of the deceased), or *κίονες*, pillars, of different size and design, or sarcophagi plain and ornamental. To these must be added statue-bases of every kind, often inscribed, not only with the names and honors of individuals, but also with decrees and other documents. All these forms were intended to stand by themselves in the open air. But it was also common to inscribe state documents upon the surface of the walls of a temple, or other public building. Thus the cella-walls of the temple of Athena Polias at Priene were covered with copies of the awards made concerning the lands disputed between Samos and Priene (*C. I. G.*, 2905, and *infra*); similarly the walls of the Artemisium at Ephesus contained a number of decrees (Wood's *Ephesus*, appendix), and the *proscenium* of the Odeum was lined with *crustæ*, or "marble-veneering," under 1 inch thick, inscribed with copies of letters from Hadrian, Antoninus, and other emperors to the Ephesian people (Wood, *ibid.*, p. 44). The workmanship and appearance of inscriptions varied considerably according to the period of artistic development. The letters incised with the chisel upon the wall or the *στήλη* were painted in with red or blue pigment, which is often traceable upon newly unearthed inscriptions. When Thucydides, in quoting the epigram of Pisistratus the younger (vi. 54), says, "it may still be read *ἀμυδροῖς γράμμασι*," he must refer to the fading of the color; for the inscription was brought to light in 1877 with the letters as fresh as when they were first chiselled (see Kumanudes in Ἀθήναιον, vi. p. 149; *Corpus Inscr. Att.*, suppl. to vol. i. p. 41). The Greeks found no inconvenience, as we should, in the bulkiness of inscriptions as a means of keeping public records. On the contrary they made every temple a muniment room; and while the innumerable *στῆλαι*, *Hermæ*, bases, and altars served to adorn the city, it must also have encouraged and educated the sense of patriotism for the citizen to move continually among the records of the past. The history of a Greek city was literally written upon her stones.

Value of inscriptions.

The primary value of an inscription lay in its documentary evidence (so Euripides, *Suppl.* 1202, foll.). In this way they are continually cited and put in evidence by the orators (*e.g.*, see Demosth., *Fals. Leg.*, 428; Æschin., *In Ctes.*, § 75). But the Greek historians also were not slow to recognize their importance. Herodotus often cites them (iv. 88, 90, 91; v. 58 *sq.*; vii. 228); and in his account of the victory of Platæa he had his eye upon the tripod-inscription (ix. 81; *cf.* Thuc. i. 132). Thucydides's use of inscriptions is illustrated by v. 18 foll., 23, 47, 77; vi. 54, 59. Polybius used them still more. In later Greece, when men's thoughts were thrown back upon the past, regular collections of inscriptions began to be made by such writers as Philochorus (300 B. C.), Polemo (2d century B. C., called *στηλοκόπας* for his devotion to inscriptions), Aristodemus, Craterus of Macedon, and many others.

---

[1] The legends on coins form part of numismatics, though closely connected with inscriptions.

[2] The amphoræ which conveyed the wine and other products of various localities have imprinted on their handles the name of the magistrate and other marks of the place and date. Large collections have been made of them, and they repay inquiry. See Dumont, *Inscriptions Céramiques*, 1872; Paul Becker, *Henkelinschriften*, Leipsic, pt. i. 1862, pt. ii. 1863.

[3] *E.g.*, treaty between Elis and the Heræans, about 500 B. C., from Olympia (Boeckh, *C. I. G.*, 11); a similar bronze from Olympia, recently discovered (*Archäol. Zeitung*, 1877, p. 196); a similar bronze treaty from the Locri Ozolæ (Rangabé, *Ant. Hellén.*, 356*b*); bronze plate from Dodona, recording the victory of Athens over the Lacedæmonians in a sea-fight, probably 459 B. C. (*Archäol. Zeitung*, 1878, p. 71).

[4] See Franz, *Elem. Epigr. Gr.*, p. 168, etc.

[5] See Karapanos, *Dodone et ses ruines.*

[6] What was done by Themistocles under stress of public necessity (Thucyd., i. 93) was done by others with less justification elsewhere; and from Byzantine times onward Greek temples and inscriptions were found convenient quarries.

[7] It appears from Cicero, *De Legibus*, ii. 26, 27, that the size of Athenian gravestones was limited by law.

Modern collectors and editors.

At the revival of learning, the study of inscriptions revived with the renewed interest in Greek literature. Cyriac of Ancona, early in the 15th century, copied a vast number of inscriptions during his travels in Greece and Asia Minor; his MS. collections were deposited in the Barberini library at Rome, and have been used by other scholars. (See *Bulletin* of the French archæological school at Athens, vol. i.) Succeeding generations of travellers and scholars continued to collect and edit, and Englishmen in both capacities did much for this study.

Thus early in this century the store of known Greek inscriptions had so far accumulated that the time had come for a comprehensive survey of the whole subject. And it was the work of one great scholar, Augustus Boeckh, to raise Greek epigraphy into a science. At the request of the Academy of Berlin he undertook to arrange and edit all the known inscriptions in one systematic work, and vol. i. of the *Corpus Inscriptionum Græcarum* was published in 1828, vol. ii. in 1833. He lived to see the work completed, although other scholars were called in to help him to execute his great design; vol. iii., by Franz, appeared in 1853; vol. iv., by Kirchhoff, in 1856.[1] The work is a masterpiece of lucid arrangement, profound learning, untiring industry, and brilliant generalization. Out of the publication of the *Corpus* there grew up a new school of students, who devoted themselves to discovering and editing new texts, and working up epigraphical results into monographs upon the many-sided history of Greece. In the *Corpus* Boeckh had settled for ever the methods of Greek epigraphy; and in his *Staatshaushaltung der Athener* (well known to English readers from Sir G. C. Lewis's translation, *The Public Economy of Athens*, 2d ed., 1842), he had given a palmary specimen of the application of epigraphy to historical studies. At the same time Franz drew up a valuable introduction to the study of inscriptions in his *Elementa Epigraphices Græcæ* (1840).

Meanwhile the liberation of Greece and increasing facilities for visiting the Levant combined to encourage the growth of the subject, which has been advanced by the labors of many scholars, and chiefly Ludwig Ross, Leake, Pittakys, Rangabé, Le Bas, and later by Meier, Sauppe, Kirchhoff, Kumanudes, Waddington. Together with the development of this school of writers, there has gone on a systematic exploration of some of the most famous sites of antiquity, with the result of exhuming vast numbers of inscriptions. Cyrene, Halicarnassus, Cnidus, Priene, Rhodes, and Ephesus have been explored by the English; Athens, Eleusis, and Dodona by the English and the Greeks; Olympia by the Greeks and Germans; Cyprus by General Cesnola; Delphi and Delos by the French; and Pergamos by the Germans. A German and a French institute have been established at Athens, chiefly engaged in the study of inscriptions. And still the work proceeds at a rapid rate. For indeed the yield of inscriptions is practically inexhaustible: each island, every city, was a separate centre of corporate life, and it is significant to note that in the island of Calymnos alone Mr. Newton collected over one hundred inscriptions, many of them of considerable interest.

The result of this has been that Boeckh's great work, though it never can be superseded, yet has ceased to be what its name implies. The four volumes of the *C. I. G.* contain about 10,000 inscriptions. But the number of Greek inscriptions now known has been estimated at 20,000 or 30,000. Many of these are only to be found published in the scattered literature of dissertations, or in Greek, German, and other periodicals. But several comprehensive collections have been attempted, among which may be named—Rangabé, *Antiquités Helléniques*, 2 vols. 1842–1855; Keil, *Sylloge Inscriptionum Bœoticarum*, 1847; Kumanudes, *Ἀττικῆς ἐπιγραφαὶ ἐπιτύμβιοι*, 1871; Le Bas, *Voyage Archéologique*, vols. i.–iii., in course of continuation by M. Waddington; *Greek Inscriptions in the British Museum*, edited by C. T. Newton, pt. i., "Attika," by E. L. Hicks, 1874; and above all the *Corpus Inscriptionum Atticarum*, undertaken by the Berlin Academy, of which there have already appeared vol. i. by Kirchhoff, 1873 (with supplement, by the same, 1877); vol. ii. pt. 1, by Köhler, 1877; vol. iii. pt. 1, by Dittenberger, 1878.

Oldest Greek inscriptions.

The oldest extant Greek inscriptions appear to date from the middle of the 7th century B. C. During the recent excavations at Olympia a number of fragments of very ancient inscriptions have been found, which have been published in the recent numbers of the *Archäologische Zeitung* (1878–1880). But what is wanted is a sufficient number of very early inscriptions of fixed date. One such exists upon the leg of a colossal Egyptian statue at Abu-Simbel on the upper Nile, where certain Greek mercenaries in the service of King Psammetichus recorded their names, as having explored the river up to the second cataract (*C. I. G.*, 5126). Even if Psammetichus II. is meant, the inscription dates between 594 and 589 B. C. Documents earlier than the Persian war are not very frequent; but after that period the stream of Greek inscriptions goes on, generally increasing in volume, down to late Byzantine times.

Classification.

Greek inscriptions may most conveniently be classified under the following heads:—(1) those which illustrate political history; (2) those connected with religion; (3) those of a private character.

Political inscriptions.

1. Foremost among the inscriptions which illustrate Greek history and politics are the *decrees* of senate and people (*ψηφίσματα βουλῆς, ἐκκλησίας*, etc.) upon every subject which could concern the interests of the state. These abound from every part of Greece. It is true that a large number of them are honorary, *i. e.*, merely decrees granting public honors (crowns, statues, citizenship, and other privileges) to strangers who have done service to the particular city. But the importance of an honorary decree depends upon the individual and the services to which it refers. And even the mere headings and datings of the decrees from various states afford curious and valuable information upon the names and titles of the local magistrates, the names of months, and other details. Droysen in his *Hellenismus* (1877–78) has shown how the history of Alexander and his successors is illustrated by contemporary *ψηφίσματα*. And when the student of Athenian politics of the 5th and 4th centuries turns to the 2d volume of the *C. I. A.*, he may wonder at the abundance of material before him; it is like turning over the minutes of the Athenian parliament. One example out of many must suffice:—No. 17 in *C. I. A.*, ii. pt. 1, is the famous decree of the archonship of Nausinicus (378 B. C.) concerning the reconstruction of the Athenian confederacy. The terms of admission to the league occupy the face of the marble; at the bottom and on the left edge are inscribed the names of states which had already joined.

Inscribed *laws* (*νόμοι*) occur with tolerable frequency. The following are examples:—A citation of a law of Draco's from the *πρῶτος ἄξων* of Solon's laws (*C. I. A.*, i. 61; *cf. Hermes*, ii. p. 27); a reassessment of the tribute payable by the Athenian allies in 425 B. C. (*C. I. A.*, i. 37; Köhler, *Urkunden und Untersuchungen zur Geschichte des Delisch-attischen Bundes*, 1870, p. 63); a law passed by the Amphictyonic council at Delphi, 380 B. C. (Boeckh, *C. I. G.*, 1688; *C. I. A.*, ii. 545); law concerning Athenian weights and measures (Boeckh, *Staatshaushaltung*, vol. ii. p. 356; *C. I. G.*, 123); the futile sumptuary law of Diocletian concerning the maximum prices for all articles sold throughout the empire (Waddington, *Édit de Dioclétien*, 1864; Mommsen, *C. I. Lat.*, vol. iii. pt. 2, 801 *sq.*).

---

[1] An index to the four volumes was long wanting; it was at length completed and appeared in 1877.

Besides the inscribed *treaties* previously referred to, we may instance the following:—Between Athens and Chalcis in Eubœa, 445 B.C. (*C. I. A.*, suppl. to vol. i., 27*a*); between Athens and Rhegium, 433 B.C. (*C. I. A.*, i. 33, and suppl. *ibid.*, p. 13); between Athens and Leontini, dated the same day as the preceding (*C. I. A.*, suppl. to vol. i. 33*a*); between Athens and Bœotia, 395 B.C. (*C. I. A.*, ii. 6); between Athens and Chalcis, 378 B.C. (*ibid.*, p. 398); between Athens and Sparta, 271 B.C. (*C. I. A.*, ii. No. 332); between Hermias of Atarneus and the Ionian Erytheræ, about 350 B.C. (Le Bas and Waddington, *Voyage Arch.*, iii. 1536*a*); treaties in the local dialect between various cities of Crete, 3d century B.C. (*C. I. G.*, 2554–6; Rangabé, *Ant. Hellén.*, 2478; *Hermes*, iv. 266). Egger's *Études historiques sur les traités publics chez les Grecs et chez les Romains* (Paris, 1866) embraces a good many of these documents.

The international relation of Greek cities is further illustrated by *awards* of disputed lands, delivered by a third city called in (ἔκκλητος πόλις) to arbitrate between the contending states, *e.g.*, Rhodian award as between Samos and Priene (*C. I. G.*, 2905; Le Bas and Wadd., *Voy. Arch.*, iii. No. 189 *sq.*); Milesian between Messenians and Spartans, recently discovered at Olympia (*Arch. Zeit.*, 1876, p. 128; see Tac., *Ann.* iv. 43); and many others. Akin to these are decrees in honor of judges called in from a neutral city (ξενικὸν δικαστήριον) to try suits between citizens which were complicated by political partisanship (see *C. I. G.*, No. 2349*b*, and Boeckh's remarks).

Letters from kings are frequent; as from Lysimachus to the Samians (*C. I. G.*, 2254); from Antigonus I. directing the transfer of the population of Lebedus to Teos (Le Bas-Wadd., *Voy. Arch.*, iii. No. 86). Letters from Roman emperors are commoner still: such as *C. I. G.*, 3175, 3176, 3178, 3834.

The internal administration of Greek towns is illustrated by the minute and complete lists of the treasures in the Parthenon of the time of the Peloponnesian war (Boeckh, *Staatshaush.*, vol. ii.); public accounts of Athenian expenditure (*ibid.*); records of the Athenian navy in the 4th century, forming vol. iii. of the same work. The management of public lands and mines is specially illustrated from inscriptions (*ibid.*, vol. i. *passim*); and the political constitution of different cities often receives light from inscriptions which cannot be gained elsewhere (*e. g.*, see the document from Cyzicus, *C. I. G.*, 3665, and Boeckh's note).

Inscriptions in honor of kings and emperors are very common. The *Marmor Ancyranum* has already been mentioned; but an earlier example is the *Monumentum Adulitanum* (from Abyssinia, *C. I. G.*, 5127) reciting the achievements of Ptolemy Euergetes I. Offerings in temples (ἀναθήματα) are often of great historical value, *e.g.*, the helmet of Hiero, now in the British Museum, dedicated at Olympia after his victory over the Etruscans, 474 B.C. (*C. I. G.*, 16); and the bronze base of the golden tripod dedicated at Delphi after the victory of Platæa, and carried off to Constantinople by Constantine (Déthier und Mordtmann, *Epigraphik von Byzantion*, 1874).

Religious inscriptions.

2. The religion of Greece in its external aspects is the subject of a great number of inscriptions. The following are a few specimens. (1) Institution of festivals, with elaborate ritual directions—see Sauppe, *Die Mysterieninschrift aus Andania*, 1860, and the singular document from the Ephesian theatre, in Wood's *Ephesus*, appendix vi. 1; the following also relate to festivals—*C. I. G.*, 1845, 2360, 2715, 3059, 3599, 3641*b*. (2) Laws defining the appointment, duties, or perquisites of the priesthood—*C. I. G.*, 2656; *Staatshaush.*, ii. p. 121 *sq.* (3) Curious calendar of sacrifices from Myconus, Ἀθήναιον, ii. p. 237. (4) Fragment of augury rules, Ephesus, 6th century B.C., *C. I. G.*, 2953. (5) Leases of τεμένη and sacred lands—*C. I. G.*, 103, 104, 2693*d*, 2694; Le Bas and Wadd., *Voy. Arch.*, iii. No. 415, etc. (6) Imprecations written on lead, and placed in tombs or in temples—Franz, *El. Epigr. Gr.*, p. 168; Newton, *Cnidus, Halicarnassus, and Branchidæ*, pl. 7, 13. (7) Oracles are referred to—*C. I. G.*, ii. p. 1091 (Ross, *Archäol. Aufs.*, p. 495); *C. I. G.*, 2717. (8) Among the inscriptions from Delphi few are more curious than those relating to the enfranchisement of slaves under the form of sale to a god (see Faucart, *Sur l'affranchissement des esclaves par forme de vente*, etc., Paris, 1857). This catalogue might be enlarged indefinitely.

Private inscriptions.

3. There remain a large number of inscriptions of a more strictly private character. The famous Parian marble (*C. I. G.*, 2374) falls under this head; it was a system of chronology drawn up, perhaps by a schoolmaster, in the 3d century B.C. The excessive devotion of the later Greeks to athletic and other competitions at festivals is revealed by the numerous dedications made by victorious competitors who record their successes (see *C. I. G.*, *passim*). The dedications and honorary inscriptions relating to the Ephebi of later Athens (which occupy half of *C. I. A.*, iii. pt. 1), dreary as they seem, have yet thrown a curious light upon the academic life of Roman Athens (see A. Dumont, *Essai sur l'Éphébie Attique*); and from these and similar late inscriptions the attempt has been made to construct *Fasti* of the later archons (Dumont, *Essai sur la chronologie des Archontes Athéniens*, 1870; R. Neubauer, *Commentationes Epigraphicæ*, 1869; Westermann in Pauly's *Real-Encyclopädie*, vol. i., new ed., *s. v.* Archontes). The sepulchral monuments have been beautifully illustrated in Stackelberg's *Gräber der Hellenen* (*cf.* Pervanoglu, *Die Grabsteine d. alt. Griechen*, Leipsic, 1863). Some of the most interesting epitaphs in the *C. I. G.*, are from Aphrodisias and Smyrna. Kumanude's collection of Attic epitaphs has been mentioned above; they yield a good deal of information about the Attic demes, and some of them are of high importance, *e.g.*, the epitaph on the slain in the year 458 B.C. (*C. I. G.*, 165), and on those who fell before Potidæa (*C. I. A.*, i. 442). Closely connected with sepulchral inscriptions is the famous "Will of Epicteta" (*C. I. G.*, 2448). It was also customary at Athens for lands mortgaged to be indicated by boundary-stones inscribed with the names of mortgager and mortgagee, and the amount (Franz, *El. Epigr. Gr.*, p. 168, 338); other ὅροι are common enough.

The names of sculptors inscribed on the bases of statues were collected in 1871 by G. Hirschfeld (*Tituli Statuariorum Sculptorumque*); but since then the number has been greatly increased by excavations at Olympia and elsewhere. In most cases the artists are unknown to fame. Among the exceptions are the names of Pythagoras of Rhegium, whom we now know to have been a native of Samos (*Arch. Zeit.*, 1878, p. 82), Polyclitus the younger (*Arch. Zeit.*, 1878, p. 12), and Pæonius of Mende, who sculptured the marble Nike at Olympia (*Arch. Zeit.*, 1875, p. 178).

Study of dialects.

The bearing of inscriptions upon the study of dialects is very obvious. A handy collection has been made by Cauer (*Delectus Inscr. Gr.*, Leipsic, 1877) of the principal inscriptions illustrating this subject; and the dialect of the Athenian dramatists has been illustrated from inscriptions by Wecklein (*Curæ Epigr. ad Grammaticam Græcam et Poetas scenicos pertinentes*, Leipsic, 1869).

Date of inscriptions.

The date of inscriptions is determined partly by the internal evidence of the subject, persons, and events treated of, and the character of the dialect and language. But the most important evidence is the form of the letters and style of execution. Much of this evidence is of a kind difficult to appreciate from a mere description. Yet—besides the βουστροφηδόν writing of many early documents—we may mention the contrast between the stiff, angular characters which prevailed before 500 or 450 B.C. and the graceful yet simple forms of the Periclean age. This development was part of the general movement of the time. Inscriptions of this period are usually written στοιχηδόν, *i.e.*, the letters are in line vertically as well as horizontally. From the archonship of Euclides (403 B.C.) onwards, the Athenians adopted the fuller alphabet which had obtained in Ionia since the 6th century. Before 403 B.C. ξ and ψ were expressed in Attic inscriptions by ΧΣ and ΦΣ, while Ε did duty for η, ϵ, and sometimes ϵι, Ο for ο, ου, and ω,—Η being used only for the aspirate. The documents of Lycurgus's administration are recognized by their small, neat characters, very carefully inscribed. The Macedonian period betrays a falling off in neatness and firmness of execution,—the letters being usually small and scratchy, excepting in inscriptions relating to great personages, when the characters are often very large and handsome. At this time came in the use of *apices* as an ornament of letters. These tendencies increased during the period of Roman dominion in Greece, and gradually, especially in Asia Minor, the *iota adscriptum* was dropped. The Greek characters of the Augustan age indicate a period of restoration; they are uniformly clear, handsome, and adorned with *apices*. Under the empire the characters fast degenerated, combining increased ornament with less delicacy of execution. In the 2d or 3d century, if not earlier, the circular and square *sigma* (C, ⊏) occur, together with the circular *epsilon* (Є). There are a good many pretty inscriptions under the Antonines; but later the writing grows more coarse and clumsy until Byzantine times, when the forms appear barbarous indeed beside an inscription of the Augustan or even Antonine age.

Collections of marbles.

The finest collections of inscribed Greek marbles are of course at Athens. There are also good collections, public and private, at Smyrna and Constantinople. The British Museum contains the best collection out of Athens (now being edited);

the Louvre contains a good many (edited by Fröhner, *Les inscriptions Grecques du musée du Louvre*, 1865); the Oxford collection is very valuable, and fairly large; and there are some valuable inscriptions also at Cambridge.

The following essays give good outlines of the whole subject:—Boeckh, *C. I. G.*, preface to vol. i.; Westermann in Pauly's *Real-Encycl.*, s. v. Inscriptiones; Egger, "Des collections d'inscriptions Grecques" in *Journal des Savants*, 1871; C. T, Newton, *Essays on Art and Archæology*, 1880, p. 95, 209. Besides the works already quoted, the following should be mentioned:—Boeckh's *Kleine Schriften;* Wescher-Foucart, *Inscriptions recueillies à Delphes*, 1863; Michaelis, *Der Parthenon;* Waddington, *Fastes des Provinces Asiatiques*, part i., 1872, and *Mémoire sur la chronologie de la vie du rhéteur Aristide;* Kirchhoff, *Studien zur Geschichte der griechischen Alphabets*, 1867; Keil, *Specimen Onomatologi Græci*, 1840, and *Analecta Epigraphica et Onomatologica*, 1842; C. Curtius, *Studien und Urkunden zur Geschichte von Samos*, Lübeck, 1877; Meier, *De proxenia*, 1843, and *Die privatschiedsrichter und die öffentlichen Diäteten Athens*, Halle, 1846; Bétant, *An fuerint apud Græcos judices certi litibus inter civitates componendis*, diss. inaug., Berl., 1862; Foucart, *Des Associations Religieuses chez les Grecs*, Paris, 1873; Lüders, *Die Dionysischen Künstler*, Berl., 1873. (E. L. H.)

V. ROMAN.

I. Roman Inscriptions (by which general name are designated, in classical archæology, all non-literary remains of the Latin language, with the exception of coins, letters and journals) fall into two distinct classes, viz. (1) those which were written upon other objects of various kinds, to denote their peculiar purpose, and in this way have been preserved along with them; and (2) those which themselves are the objects, written, to be durable, as a rule, on metal or stone. The first class is that of *inscriptions* in the stricter sense of the word (styled by the Romans *tituli*, by the Germans *Aufschriften*); the second is that of instruments or charters, public and private (styled by the Romans first *leges*, afterwards *instrumenta* or *tabulæ*, and by the Germans *Urkunden*).

No ancient Latin authors have professedly collected and explained or handed down to us Roman inscriptions. Some of the orators and historians, such as Cicero, Livy, Pliny the elder, and Suetonius among the Latins, and Polybius, Dionysius of Halicarnassus, and Josephus among the Greeks, occasionally mention inscriptions of high historical interest. A few grammarians, as for example, Varro, Verrius Flaccus, and Valerius Probus of Berytus, quote ancient words or *formulæ* from them, or explain the abbreviations used in them. Juridical instruments, laws, constitutions of emperors, *senatus consulta*, and the like appear here and there in the various collections of Roman jurisprudence.

Inscriptions (in the wider sense, as we shall henceforth call them without regard to the distinction which has been drawn) have been found in nearly every centre of ancient Roman life, but, like many other remains of antiquity, only seldom in their original sites. The great mass of them has to be sought for in the large European museums of ancient art, and in the smaller local collections of ancient remains which occur nearly everywhere in the European provinces of the former Roman empire, as well as in the north of Africa, and also here and there in Asia Minor.

Only those copies of inscriptions are to be received with full confidence which are furnished by experienced and well-equipped scholars, or which have been made with the help of mechanical methods (casts, photographs, moist and dry rubbings), not always applicable with equal success, but depending on the position and the state of preservation of the monuments.[1] From the first revival of classical learning in the Carolingian age, attention was paid anew, by pilgrims to Rome and other places worth visiting, to epigraphic monuments also. In the time of the Renaissance, from the end of the 14th century downwards, some of the leading Italian scholars, like Poggio and Signorili, and the antiquarian traveller Cyriacus of Ancona, collected inscriptions, Greek and Latin.[2] In the 15th century large collections of the inscriptions of all countries, or of limited districts, were made by Giovanni Marcanova, Fra Felice Feliciano, Fra Michele Ferrarino, Fra Giocondo the architect of Verona, Marino Sanudo the Venetian polyhistor, and others. At the end of the 15th and the beginning of the 16th, the first printed collections can be recorded (Spreti's for Ravenna, 1489; Peutinger's for Augsburg, 1508; Huttich's for Mainz, 1520; Francesco degli Albertini's for Rome, printed in 1521 by Jacopo Mazochi), while during the same century, a long list of epigraphic travellers, like Pighius, Rambertus, and Accursius, or antiquarian collectors, like Sigonius, Panvinius, Antonius Augustinus with his collaborators Ursinus and Metellus, and many others, were busy in augmenting the stock of epigraphic monuments. The series of printed epigraphic *Corpora* begins with that of Apianus (Ingolstadt, 1534), the only one arranged in geographical order, and is continued in those of Smetius (1558, but edited only after the author's death by Justus Lipsius, 1588), Gruter (with Joseph Scaliger's *Indices*, 1603, and re-edited by Grævius, 1707), Gudius (about 1660, edited by Hessel, 1731), Reinesius (1682), Fabretti (1699), Gori (1726), Doni (1731), Muratori (1739), Maffei (1749), Donati (1765–75). These collections, manuscript and printed, will never altogether lose their value, as great numbers of inscriptions known to the ancient collectors have since been lost or destroyed. But, inasmuch as even towards the beginning of the 15th century, as well as afterwards, especially from the 16th down to a very recent period, all sorts of inaccuracies, interpolations, and even downright falsifications, found their way into the *Corpora*, these can be employed only with the greatest caution. Modern critical research in the field of epigraphy began with the detection of those forgeries (especially of the very extensive and skilful ones of Pirro Ligorio, the architect to the house of Este) by Maffei, Olivieri, and Marini. The last-named scholar opens a new era of truly critical and scientific handling of Roman inscriptions (especially in his standard work on the *Atti dei Fratelli Arvali*, Rome, 1795); his disciple and successor, Count Bartolomeo Borghesi (who died at San Marino in 1860), may be rightly called the founder of the modern science of Roman epigraphy.[3] Orelli's handy collection of Roman inscriptions (2 vols., Zurich, 1828) is a first attempt to make accessible to a larger scientific public the results of the researches of Marini and his successors; but it was not completed (and thoroughly corrected) until nearly thirty years later, by Henzen (Orelli, vol. iii., with the indispensable *Indices*, Zurich, 1856), who, with Mommsen and De Rossi, carried out the plan of a universal *Corpus Inscriptionum Latinarum*, previously projected by Maffei (1732), by Kellermann and Sarti (1832), with Borghesi's help, and by Letronne and Egger (1843). After the appearance of Mommsen's *Inscriptiones regni Neapolitani Latinæ* (Leipsic, 1852) and his *Inscriptiones Confœderationis Helveticæ Latinæ* (vol. x. of the publications of the Zurich Antiquarian Society, 1854), the publication of the *C. I. L.*, following the similar work on the Greek inscriptions, was undertaken by the Royal Academy of Sciences of Berlin. This work, in which the previous literature is fully described and utilized, consists of the following parts:—vol. i., *Inscriptiones Antiquissimæ ad C. Cæsaris mortem*, by Mommsen (Berlin, 1863), with the *Fasti Consulares* by Henzen, and the *Indices* by Hübner; Ritschl's *Priscæ Latinitatis monumenta epigraphica* (Berlin, 1862, fol.) form the graphic illustration to vol. i., giving all extant monuments of the republican epoch (with five *Supplementa*, Bonn, 1862–65; R. Garrucci's *Sylloge Inscriptionum Latinarum ævi Romanæ reipublicæ usque ad C. Iulium Cæsarem plenissima*, 2 vols., Turin, 1875–77, must be used with caution); vol. ii., *Inscr. Hispaniæ* by Hübner (1869); vol. iii., *Inscr. Asiæ, provinciarum Europæ Græcarum, Illyriæ*, by Mommsen; vol. iv., *Inscr. parietariæ Pompeianæ*

---

[1] See E. Hübner, *Ueber mechanische Copieen von Inschriften*, Berlin, 1881.

[2] Compare De Rossi, *Bullettino dell' Instituto archeologico*, 1871, p. 1 *sq.*

[3] Of his works, published by the French Government, nine volumes 4to (Paris 1862–80) have already appeared.

Herculanenses Stabianæ (the scratched and painted inscriptions chiefly of Pompeii) by Zangemeister (1871); vol. v., *Inscr. Galliæ cisalpinæ*, that is, *regionis Italiæ decimæ* and *undecimæ et nonæ* (1872–77); vol. vi., part i., *Inscr. urbis Romæ*, by Henzen (part ii. in the press); vol. vii., *Inscr. Britanniæ*, by Hübner (1873); vol. viii., *Inscr. Africæ*, by Wilmanns and Mommsen (to be published in 1881; here Renier's *Inscriptions Romaines de l'Algérie*, Paris, 1855–1860, though not finished, may be consulted); vols. ix. and x., *Inscr. Italiæ inferioris*, by Mommsen (to be published in 1881 or 1882); vol. xi., *Inscr. Italiæ superioris*, by Bormann, vol. xii., *Inscr. Galliæ*, by Hirschfeld (a subject partly treated in W. Brambach's *Corpus Inscriptionum Rhenanarum*, etc., Elberfeld, 1866), vol. xiii., *Inscr. Italiæ mediæ*, by Dessau, and a concluding volume of general indexes are either in the press or in preparation. The arrangement observed in the *Corpus* is the geographical (as in Apianus); within the single towns the order of subjects (*tituli sacri, magistratuum, privatorum, etc.*, as in Smetius) is followed with some few exceptions, where the monuments are so numerous (as in the *forum* of Rome—see H. Jordan, "Sylloge inscr. fori Romani," *Ephem. epigr.*, iii. p. 237 *sq.*—and at Pompeii and Lambæsis) that they can be assigned to their original places. Running supplements to the *C. I. L.* are given in the *Ephemeris epigraphica, Corporis Inscr. Latinarum Supplementum* (4 vols., Berlin, 1872–80). The inscriptions in the other Italian dialects have been published by Aufrecht and Kirchhoff (*Die umbrischen Sprachdenkmäler*, 2 vols., Berlin, 1849–51), Mommsen (*Die unteritalischen Dialecte*, Leipsic, 1850), Fabretti (*Corpus Inscriptionum Italicarum antiquioris ævi*, Turin, 1867, with three supplements, *ibid.*, 1872–77), Corssen (*Ueber die Sprache der Etrusker*, 2 vols., Leipsic, 1874–75; see also Deecke, *Etruskische Forschungen*, i. to iv., Stuttgart, 1875–80); for farther particulars on the Italian dialects see Hübner's *Grundriss zu Vorlesungen über die lateinische Grammatik*, 2d ed., Berlin, 1880, p. 9). For the Christian inscriptions of Rome, and of Gaul, Spain, and Britain, see De Rossi's *Inscr. Christianæ urbis Romæ septimo sæculo antiquiores*, vol. i. (Rome, 1857), and the same author's *Roma sotterranea* (3 vols., Rome, 1861–77), with the *Bullettino di Archeologia cristiana* (Rome, 1873–80), the *Inscriptions Chrétiennes de la Gaule* of Le Blant (2 vols., Paris, 1857–65), and the *Inscr. Hispaniæ Christianæ* and *Inscr. Britanniæ Christianæ* of Hübner (Berlin, 1871, 1876). As splendidly illustrated works on the Latin inscriptions of some districts, Alphonse de Boissieu's *Inscriptions antiques de Lyon* (Lyons, 1846–54), Ch. Robert's *Epigraphie romaine de la Moselle* (Paris, 1875), and J. C. Bruce's *Lapidarium septentrionale* (London and Newcastle, 1875) can be recommended. Besides the above-mentioned Orelli-Henzen collection, G. Wilmann's *Exempla Inscriptionum Latinarum* (2 vols., Berlin, 1873, with copious indexes) gives a general synopsis of the materials.

II. The alphabet used by the Romans is identical with that of the Chalcidian colonies in southern Italy and Sicily (viz., Cyme, Neapolis, Rhegium, Zancle, Naxos, and Himera), except the three aspirates θ, ϕ, χ; these, being of no use in ancient Latin, which had no such aspirates, were employed as numerals. The old Z, which occupied the seventh place in the alphabet, being of rare employment, was replaced, as early as the 4th century A. U. C., by G, a letter formed by the addition of a stroke out of the old gamma C, which became identical in sound with K, though remaining in use as an abbreviation for *Gaius* and *Gnæus*. To that standard alphabet of twenty-one letters were appended, in Cicero's time, the Greek letters υ and ζ. In this alphabet (A B C D E F G H I K L M N O P Q R S T V X Y Z, in this form found written on the walls of Pompeii, on tiles and other monuments) the forms of the single letters vary not inconsiderably, according to the material of the monuments, their age, and their origin. Carefully cut letters, especially when on a large scale, naturally differ from those scratched or painted on walls by non-professional hands, or hewn on rocks by soldiers; and small incised (or dotted) letters on metal or ivory and bone, and those painted on earthenware, or impressed on it or on glass before burning, are also necessarily of a different character. The letters, ordinarily drawn with *minium* on the monument before being cut (and also often painted, after having been cut, with the same color), sometimes have been painted with a brush, and thence receive a peculiar form. A, in the most ancient period (before the Second Punic War), appears in these forms, Λ Λ Λ; L, in the same epoch, is acute-angled (as in the Chalcidian alphabet), ∨; P, is rectilineal, Γ; Q, has a perpendicular stroke, ϙ; B, D, R, S are often not rounded, but acute-angled (ᛒ ▷ R ϟ); O and Q appear sometimes not closed (∩, Q). Besides E and F (which usually have their horizontal strokes of equal length and not as in modern printing), there were in use some quasi-cursive forms, I' and II; and besides M (which, at the best periods, has its two exterior strokes inclined, not perpendicular, and the middle point extended to the foot of the line), a cursive IIII is to be found. In later periods, F is sometimes elevated above the other letters (and afterwards not F only), G assumes the form ɕ, H appears as ⱶ, and L as ᚴ,—to mention only some prominent diversities, for a complete history of the palæographic changes of the Roman alphabet has not yet been written. In general the old quadrate forms of the letters, with equal breadth of strokes above and below, become, by degrees, more slender and elegant, the tops and angles being slightly curved, etc. Additions to the Roman alphabet were made, but without permanent success, by the emperor Claudius (Ⅎ for V the consonant, to distinguish it from V the vowel, Ↄ for the Greek ψ, Ⱶ for the sound between *i* and *u*, as in *bybliotheca*; he wrote also *ai* for *ae*). To distinguish, after the later Greek usage, long from short vowels, in the course of the 7th century A. U. C. the plan of doubling them was introduced for *a*, *e*, and *o* (not *u*), while the long *i* was written *ei*, and afterwards indicated by the prolonged form ꟾ. At the end of the republic these distinctions disappear, and long vowels are distinguished, when at all, by an *apex* (a stroke or a curved line upon them ´, not an accent), down to the epoch of the emperor Marcus Aurelius. In some very rare instances the doubling of consonants is indicated by a *sicilicus*, a hook (') upon them. The double *i* indicates, in some examples, from Cæsar down to Domitian, the consonantal *j* (as in *cuiius*, *eiius*), To save space, on coins first and afterwards in inscriptions also, two or three or even more letters were joined, especially at the end of the lines, to a *nexus* or a *ligatura*. This system of compendious writing, very rare in the republican epoch, and slowly extending itself during the 1st century, became rather frequent in the 2d and 3d, especially in Spain and Africa. There is no constant system in these *nexus literarum*, but generally the rule is observed that no substantial element of a single letter is to be counted for twice (thus, *e. g.*, † is *it* or *ti*, not *Titi*). In the republican period, the numbers from one to nine are mostly written in the *additive* form (I II III IIII V VI VII VIII VIIII), and similarly in combination with X, XX, and so on (XXXX, LXXXX); V, for five, seems to be a graphic division of X. The χ of the Chalcidian alphabet, ↓, is the numeral for fifty (afterwards ⊥ and L, which has originally nothing to do with the letter L); the ϑ, ⊙, is that for a hundred (replaced early by the initial of the word *centum*, C); the φ, ⌽, is that for a thousand (afterwards M, the initial of *mille*), of which ↀ, ∞ are only slight graphic alterations. The multiples of a thousand by 10 are written thus ↂ (10,000), ↈ (100,000). From ⌽ came, by graphic division, Ⅾ (not D the letter) for 500 (with ↁ 5000, ↇ 50,000). A peculiar mark (ɑↄ) appears rarely for 500,000 (*Hermes*, iii., 1868, p. 467). Numerals are usually distinguished from letters in the ancient period, down to the end of the republic, by a stroke drawn through them, as in ĦVIR, *duo*(*m*) *vir*(*om*) ĦS *duo semis* (*sestertius*), Đ 500; it was afterwards put above them, as in $\overline{\text{II}}$VIR, $\overline{\text{X}}$VIR, I$\overline{\text{IIII}}$IVIR, *duovir*, *decemvir*, *sevir*.[1]

The direction of the writing is, even in the oldest inscriptions, from left to right; there exists only one very ancient example of an inscription, found at the lake Fucinus, written in a kind of *βουστροφηδόν* arrangement (H. Jordan, *Hermes*, vol. xv., 1880, p. 5), while in the Sabellic inscriptions similar arrangements are not infrequent. Each word is separated from the other by a sign of interpunction, which is not wanted, therefore, at the end of lines or of the whole text. Exceptions to this rule occur only in the later period (from the 2d century downwards), and sometimes under special conditions, as when abridged words form the end of the line. Here and there even the different syllables of each word are separated by interpunction. The interpunction is formed by a single dot (except in some very ancient inscriptions, such as those of Pisaurum, where, as in Greek and other Italian monuments, three dots ⁝ are used), which, according to the technical skill of the different periods in stone-cutting, is in some very ancient inscriptions quadrangular, or similar to an oblique cross (×), or oblong (as a bold stroke), but, as a rule, triangular, and never circular. This triangular dot changes, by ornamentation, into a hook (❜) or a leaf (❦); the ivy-leaf-shaped dot is especially frequent in inscriptions from about the 2d century downwards. The dot is always placed at the middle height of the letters, not, as now, at the foot of the line. In large texts of instruments the interpunction is often omitted; in the later period it is often entirely wanting; and in short texts, in the disposition of the lines, in the varying sizes of the letters employed, in the division of words at the end of the lines, etc., certain rules are observed, which cannot be detailed here. In some instances older inscriptions have been cancelled and more recent ones substituted (*e. g.*, on milestones), especially in the case of the *damnatio memoriæ* (in cases of high treason), in consequence of which the names of consuls and emperors are often cancelled; but in modern times also inscriptions have been deliberately destroyed or lost ones restored.

For understanding the texts of the inscriptions an accurate knowledge of the system of abbreviations used in them is necessary. These are almost invariably *litteræ singulares;* that is to say, the initial letter is employed for the entire word (in all its grammatical forms), or, if one initial, as belonging to more than one word, is not sufficiently clear, the first two or even the first three letters are employed; rarely more than three. Abbreviations in the true sense of the word (by dropping some letters at the end) are to be found, in the older period, only at the end of lines, and not frequently. In the later period some instances of them have been observed. The *litteræ singulares*, as Valerius Probus taught, are either generally employed (*usus generalis*) in all classes of written documents (and so in literature also), as, for instance, those of the individual names (the *prænomina*), the names of days and feasts (*kal.* for *kalendæ*), and those of the chief magistrates (*cos.* for *consul*) and the like; or they belong chiefly (but not exclusively) to certain classes of documents, such as those used in juridical acts (*l.* for *lex*, *h.* for *heres*, *s. d. m.* for *sine dolo malo*, and so on), in sepulchral inscriptions (*h. s. e.*, *hic situs est*) or in dedicatory inscriptions (*v. s. l. m.*, *votum solvit libens merito*), etc.[2]

It may be observed here that the *prænomina* are, as a rule, always written in the universally known abbreviations (in the few instances where they are written in full, it is a consequence of Greek influence or of peculiar circumstances). The *gentilicia* in *-ius* are abridged, in the republican period, in *-i* (in the nominative, perhaps for *-is*). In the always abbreviated indications of ancestors or patrons (in the case of slaves and freedmen), as *C. f.*, *Gai filius*, *M. l.*, *Marci libertus* (*s.* for *servus* is not frequent), the feminine gender is sometimes indicated by inversion of the letters. Thus Ɔ. *l.* (or *lib.*) or W (an inverted M) *l.* designates a *mulieris libertus;* ꟻ and ⅂ are used for *filia pupilla.* On the *tribus* and their abbreviations, and on the so-called military *tribus* (which are names of colonies collocated, for the sake of symmetry, at the place usually occupied, in the nomenclature, by the *tribus*), and on the other indications of origin used in the designation of individuals, the indexes to the above-named works give sufficient information; on the geographical distribution of the *tribus*, see Grotefend's *Imperium Romanum tributim descriptum* (Hanover, 1863). For the abbreviations of official charges, urban and municipal, and, in the imperial period, civil and military (to which, beginning with the 4th century, some Christian designations are to be added), see also the explanations given in the indexes. Among these abbreviations the first instances are to be found of the indication of the plural number by doubling the last letter; thus *Augg.*, *Caess.*, *coss.*, *dd. nn.* (*domini nostri*), are used from the 3d century downwards (see De Rossi's preface to the *Inscriptiones Christ. urbis Romæ*) to distinguish them from *Aug.*, *Caes.*, as designating the singular. In the later period, a dot or a stroke over the abridged word, like that upon numerals, here and there indicates the abbreviation.

III.—1. Among the inscriptions in the stricter sense (the *tituli*), perhaps the oldest, and certainly the most frequent, are the *sepulchral inscriptions* (*tituli sepulcrales*). Of the different forms of Roman tombs, partly depending upon the difference between burial and cremation, which were in use side by side, the latest and a very complete account is given in Marquardt's *Handbuch der römischen Alterthümer* (vol. vii. part i., Leipsic, 1879, p. 330 *sq.*). The most ancient examples are those of a *sepulcretum* at Præneste (*C. I. L.*, i. 74, 165, 1501*a-d; Ephem. epigr.*, i. 25–131, Wil. 153); the oldest of these contain nothing but the name of the deceased in the nominative; those of more recent date give it in the genitive. The oldest and simplest form remained always in use down to Christian times; it is that used on the large tectonic monuments of the Augustan age (*e. g.*, that of Cæcilia Metella, *C. I. L.*, vi. 1274) and in the *mausolea* of most of the emperors, and is still frequent in the *tituli* of the large *columbaria* of the same age (*C. I. L.*, vi., part ii.). It was early succeeded by the list of names, given also in the nominative, when more than one individual, either dead or alive, were to be indicated as sharers of a tomb. To distinguish the members still alive, a *v* (*vivit, vivos, vivi*) was prefixed to their names (*e. g.*, *C. I. L.*, i. 1020, 1195, 1271); the deceased were sometimes marked by the *θῆτα nigrum* (*C. I. L.*, i. 1032; Wil. 158; see also *C. I. L.*, vi. 10251 *sq.*). Only the names in the nominative are shown, too, on the *sarcophagi* of the *Turpleii* and *Fourii* at Tusculum (*C. I. L.*, i. 65–72; Wil. 152), and in the oldest inscriptions on those of the *Scipiones*, painted with *minium* (*C. I. L.*, i. 29; Wil. 537), to which were added afterwards the insignia of the *magistratus curules* (*C. I. L.*, i. 31; Wil. 538) and the poetical *elogia*. Of a somewhat different kind are the inscriptions scratched without much care on very simple earthen vessels which belonged to a *sepulcretum* of the lower class, situated outside the *porta Capena* at Rome, on the Appian road, near the old church of San Cesario (*C. I. L.*, i. 882–1005, 1539, 1539*a-d* = *C. I. L.*, vi. 8211–8397; Wil. 176); they can be ascribed to the period of the Gracchi. On these *ollæ*, besides the name of the deceased, also for the most part in the nominative, but on the more recent in the genitive, the date of a day, probably that of the death, is noted; here and there *obit* (or *o.*) is added. About the same epoch, at the beginning of the 6th century, along with the growing taste for tectonic ornamentation of the tombs in the Greek style, poetical epigrams were added to the simple sepulchral *titulus*, especially amongst the half-Greek middle class rapidly increasing in Rome and Italy; Saturnian (*C. I. L.*, i. 1006), iambic (1007–1010), and dactylic (1011, compare *Annali dell' Instituto Archeologico*, vol. xxxvii., p. 308) verses become more and more frequent in epitaphs (see Wil. 548 *sq.*). In prose also short designations of the mental qualities of the deceased (*homo bonus, misericors, amans pauperum*, or *uxor frugi bona pudica*, and the like), short dialogues with the passer-by (originally borrowed from Greek poetry), as *vale-salve, salvus ire, vale et tu*, etc. (Wil. 180), then indications of his condition in his lifetime, chiefly among the Greek tradesmen and workmen, *e.g.*, *lanius de colle Viminale* (*C. I. L.*, i. 1011), *margaritarius de sacra via*. 1027, and the like, and some formulæ, such as *ossa hic sita sunt, heic cubat, heic situs est* (in republican times mostly written in full, not abridged) were added. The habit of recording the measurement of the sepulchre, on the sepulchral *cippus*, by such formulæ as *locus patet in fronte pedes tot, in agro* (or *in via*, or *retro*) *pedes tot*, seems not to be older than the Augustan age (*C. I. L.*, i. 1021, with Mommsen's note; Wil. 188). About the same time also the epitaphs more frequently state how long the deceased lived, which was formerly added only on certain occasions (*e.g.*, in the case of a premature death), and mostly in poetical form. The worship of the *dei Manes*, though undoubtedly very ancient, is not alluded to in the sepulchral inscriptions themselves until the close of the republic. Here and there, in this period, the tomb is designated as a (*locus*) *deum Maanium* (*e.g.*, at Hispellum, *C. I. L.*, i. 1410); or it is said, as on a *cippus* from Corduba in Spain (*C. I. L.*, ii. 2255; Wil. 218), *C. Sentio Sat*(*urnino*) *co*(*n*)*s*(*ule*)—that is, in the year 19 B. C.—*dei Manes receperunt Abulliam N*(*umerii*) *l*(*ibertam*) *Nigellam*. In the Augustan age the *titulus sepulcralis* begins to be confounded with the *titulus sacer;* it adopts the form of a dedication *deis Manibus* offered to the *dei Manes* (or *dei inferi Manes*, the *dei parentum* being the *Manes* of the parents) of the deceased (see Orel. 4351; Wil. 217–228). This formula, afterwards so common, is still very rare at the end of the republic, and is usually written in full, while in later times it is employed, both simply and in many varied forms (as *dis manibus sacrum*, or *d. m. et memoriæ, d. m. et genio*, or *memoriæ æternæ, paci et quieti, quieti æternæ, somno æternali*, and so on; Wil. 246), in thousands of monuments. By similar degrees the *titulus sepulcralis* adopts many of the elements of the *titulus honorarius* (the indication of the *cursus honorum*, of the military charges, etc., as *e.g.*, in the inscription of Cn. Calpurnius Piso, *C. I. L.*, i. 598 = vi. 1276, Wil. 1105, on the pyramid of Cestius, *C. I. L.*, vi. 1374, and on the monument at Ponte Lucano of Ti. Plautius Silvanus Ælianus, consul 74 A. D., Orel. 750, Wil. 1145, and many others), of the *tituli operum publicorum* (*e.g.*, *monumentum fecit, sibi et suis*, etc.), and of the *instrumenta*. Testaments (like those of Dasumius of the year 109 A. D.—*C. I. L.*, vi. 10229, Wil. 314, and T. Flavius Syntrophus—*C. I. L.*, vi. 10239, Henz. 7321, Wil. 313), or parts of them (like that on the tomb of a Gaul of the tribe of the Lingones, belonging to Vespasian's time, Wil. 315), funeral orations (as those on Turia, the wife of Q. Lucretius Vespillo, consul 19 B. C. —*C. I. L.*, vi. 1527, in Orel. 4859 incomplete; on Murdia—*C. I. L.*, vi., 10230, Orel. 4860, Rudorff, *Abhandlungen der Königl. Akademie der Wissenschaften zu Berlin*, 1868, p. 217 *sq.;* and that of Hadrian on the elder Matidia, found at Tivoli—Mommsen in the same *Abhandlungen*, 1863, p. 483 *sq.*), numerous statements relating to the conservation and the employment of the monuments (*C. I. L.*, vi. 10249; Wil. 287–290), to their remaining within the family of the deceased,—from which came the frequent formula "*h*(*oc*) *m*(*onumentum*) *h*(*eredem*) *n*(*on*) *s*(*equetur*)" and the like (Wil. 280),—and relating to the annual celebration of *parentalia* (Wil. 305 *sq.*), down to the not uncommon prohibition of violation or profanation of the monument (compare, for instance, *C. I. L.*, i. 1241, Wil. 267, from Naples, "*deis inferum parentum sacrum, ni violato;*" *C. I. L.*, iii., 3955, from Siscia, "*ne quis in hac ar*(*e*)*a porcos agi facere velit;*" *C. I. L.*, ii. 2703, from Portugal, in a distich, "*quisquis honorem agitas, ita te tua gloria servet, præcipias puero ne linat hunc lapidem;*" *C. I. L.*, vi. 2357, "*hospes ad hunc tumulum ne meias ossa precantur,*" etc.; and Wil. 271–273), and the addition of the name of the stone-cutter (*C. I. L.*, v. 7670; Wil. 2490; Orel.-Henz. 6344) and of the writer of the *titulus* (De Rossi, *Inscr. Christ.*, i. p. 9, 5; Wil. 1285, 2490), with many other particulars (on which the index of Wil. p. 678 *sq.*, may be consulted), form the text of the sepulchral inscriptions of the later epoch from Augustus downwards. To these are to be added many local peculiarities of provinces (as Spain and Africa), districts (as the much-disputed *sub ascia dedicare* of the stones of Lyons and other parts of Gaul), and towns, of which a full account cannot be given here.

---

[1] For other details of numerical notation, fractions, etc., see the manuals of metrology.

[2] On the system of Roman nomenclature and the abbreviations employed in it, see Orelli, cap. viii. (with Wilmanns's *Analecta*, ii. p. 197), and especially Mommsen in *Römische Forschungen*, vol. i. p. 1 *sq.*, and in *Hermes*, iii., 1869, p. 70; on the *cognomina* (but only those occurring in ancient literature), Ellendt (*De cognomine et agnomine Romano*, Königsberg, 1853), and on the local *cognomina* of the Roman patriciate, Mommsen, *Röm. Forsch.*, ii. p. 290 *sq.;* on the *nomina gentilicia*, Hübner (*Ephem. epigr.*, ii. p. 25 *sq.*). The indexes to Orelli, Wilmanns, and the volumes of the *Corpus* may also be consulted.

2. Of the *dedicatory inscriptions* (or *tituli sacri*), the oldest known are the short indications painted (along with representations of winged *genii*, in the latest style of Græco-Italian vase painting), with white color on black earthen vessels, by which those vessels (*pocula*) are declared to be destined for the worship, public or private, of a certain divinity (*C. I. L.*, i. 43–50; *Ephem. epigr.* i. 5–6; Wil. 2827*a–i*); they give the name of the god, as that of the possessor, in the genitive (*e.g.*, *Saeturni pocolom, Lavernai pocolom*). The proper form of the dedication, the simple dative of the name of a divinity and often nothing else (as *Apolenei, Fide, Junone*, etc., which are all datives), is shown on the very primitive altars found in a sacred wood near Pisaurum (*C. I. L.*, i. 167–180; Wil. 1–14); but also the name of the dedicants (*matrona, matrona Pisaurese*, which are nomin. plur.) and the formulæ of the offering (*dono dedrot* or *dedro, donu dat*, where *dono* and *donu* are accus.) are already added to them. This most simple form (the verb in the perfect or in the present) never disappeared entirely; it occurs not infrequently also in the later periods. Nor did the dative alone, without any verb or formula, go entirely out of use (see *C. I. L.*, i. 630; Wil. 36; *C. I. L.*, i. 814 = vi. 96; Orel. 1850; Wil. 32; *C. I. L.* i. 1153; Henz. 5789; Wil. 1775). But at an early date the verb *donum dare* and some synonyms (like *donum portare, ferre, mancupio dare, parare*) were felt to be insufficient to express the dedicator's good will and his sense of the justice of the dedication, which accordingly were indicated in the expanded formula *dono dedet lub*(*e*)*s mereto* (*C. I. L.*, i. 183, *cf.* p. 555; Wil. 21; *C. I. L.*, i. 190; Wil. 22), or, with omission of the verb, *dono mere*(*to*) *lib*(*e*)*s* (*C. I. L.*, i. 182). The dative case and this formula, completely or partially employed (for *merito* alone is also used, as *C. I. L.*, i. 562, cf. *Ephem. epigr.*, ii. 353, Wil. 29), remained in solemn use. To *lubens* (or *libens*) was added *lætus* (so in Catullus, 31, 4), and, if a vow preceded the dedication, *votum solvit* (or *voto condemnatus dedit*; see *C. I. L.*, i. 1175; Henz. 5733; Wil. 142; and *C. I. L.*, ii. 1044); so, but not before the time of Augustus (see *C. I. L.*, i. 1462 = iii. 1772), the solemn formula of the dedicatory inscriptions of the later period, *v. s. l. m.* or *v. s. l. l. m.*, arose. To the same effect, and of equally ancient origin with the solemn words *dare* and *donum dare*, the word *sacrum* (or other forms of it, as *sacra*[*ara*]), conjoined with the name of a divinity in the dative, indicates a gift to it (*e. g. C. I. L.*, i. 814; Wil. 32; *C. I. L.*, i. 1200–1201; Wil. 33 *a b*); the same form is to be found also in the later period (*e.g.*, *C. I. L.*, i. 1124; Henz. 5624–5637), and gave the model for the numerous sepulchral inscriptions with *dis Manibus sacrum* mentioned before. *Sacrum* combined with a genitive very seldom occurs (Orel. 1824; Wil. 34); *ara* is found more frequently (as *ara Neptuni* and *ara Ventorum*, Orel. 1340). Dedications were frequently the results of vows; so victorious soldiers (such as L. Mummius, the conqueror of Corinth—*C. I. L.*, i. 541 *sq.*; Orel. 563; Wil. 27), and prosperous merchants (*e.g.*, the brothers Vertuleii—*C. I. L.*, i. 1175; Henz. 5733; Wil. 142) vow a tenth part of their booty (*de praedad*, as is said on the basis erected by one of the Fourii of Tusculum—*C. I. L.*, i. 63, 64; Henz. 5674; Wil. 18) or gain, and out of this dedicate a gift to Herculus or other divinities (see also *C. I. L.*, i. 1503; Wil. 24; *C. I. L.*, 1113; Wil. 43). Again, what one man had vowed, and had begun to erect, is, by his will, executed after his death by others (as the *propylum Cereris et Proserpinæ* on the Eleusinian temple, which Appius Claudius Pulcher, Cicero's well-known predecessor in the Cilician proconsulate, began—*C. I. L.*, i. 619 = iii. 347; Wil. 31); or the statue that an *ædilis* vowed is erected by himself as *duovir* (*C. I. L.*, iii. 500; Henz. 5684); what slaves had promised, they fulfil as freedmen (*C. I. L.*, 1233, *servos vovit liber solvit; C. I. L.*, 816, W. 51, "*ser*(*vos*) *vov*(*it*) *leibert*(*us*) *solv*(*it*)"), and so on. The different acts into which an offering, according to the circumstantially detailed Roman ritual, is to be divided (the *consecratio* being fulfilled only by the solemn *dedicatio*) are also specified on dedicatory inscriptions (see, for instance, *consacrare* or *consecrare*, Orel. 2503, and Henz. 6124, 6128; for *dedicare*, *C. I. L.*, i. 1159, Henz. 7024, Wil. 1782, and compare Catullus's *hunc lucum tibi dedico consecroque Priape*, fragm. 2 ap. Lachmann and Müller; for *dicare*, see the *aara leege Albana dicata* to Vediovis by the *genteiles Iuliei*, *C. I. L.*, i. 807, Orel. 1287, Wil. 101). Not exactly dedicatory, but only mentioning the origin of the gift, are the inscriptions on the pedestals of offerings (ἀναθήματα, *donaria*) out of the booty, like those of M. Claudius Marcellus from Enna (*C. I. L.*, i. 530; Wil. 25, "*Hinnad cepit*") or of M. Fulvius Nobilior, the friend of the poet Ennius, from Ætolia (*C. I. L.*, i. 534; Orel. 562; Wil. 26*a*, and *Bullettino dell' Instituto*, 1869, p. 8; *C. I. L.*, vi. 1307; Wil. 26*b*, "*Ætolia cepit*" and "*Ambracia cepit*"); they contain only the name of the dedicator, not that of the divinity. Of the similar offerings of L. Mummius, already mentioned, two only are preserved in their original poetical form, the Roman in Saturnian verses of a *carmen triumphale* (*C. I. L.*, i. 541; Orel. 563; Wil. 27*a*) and that found at Reate in dactylic hexameters (*C. I. L.*, i. 542; Wil. 27*b*); the rest of them contain only the name of the

dedicant and the dative of the community to which they were destined (*C. I. L.*, i. and Wil. *l. c.*). Of a peculiar form is the very ancient inscription on a bronze tablet, now at Munich, probably from Rome, where two *aidiles*, whose names are given at the beginning as in the other *donaria*, "*vicesma(m) parti(m)* or [*ex*] *vicesma parti Apolones* (that is, *Apollinis*) *dederi* (that is, *dedere*)" (*C. I. L.*, i. 187; Orel. 1433). Many, but not substantial, varieties arise, when old offerings are restored, (*e. g.*, *C. I. L.*, i. 638, 632 = Orel. 2135, and Wil. 48; *C. I. L.*, i. 803; Henz. 5669, 6122); or the source of the offering (*e. g.*, *de stipe*, *C. I. L.*, i. 1105; Henz. 5633*a*; *ex reditu pecuniæ, ex patrimonio suo, ex ludis, de munere gladiatorio*, and so on); or the motive (*ex jusso, ex imperio, ex visu, ex oraculo, monitu, viso moniti, somnio admonitus*, and the like), or the person or object, for which the offering was made (*C. I. L.*, i. 188, *pro poplod; Ephem. epigr.*, ii. p. 308, *pro trebibos; pro se, pro salute, in honorem domus divinæ*, etc.), are indicated; or, as in the *tituli operum publicorum*, the order of a magistrate (*de senati sententia*, *C. I. L.*, i. 560 = vi. 1306; Orel. 5351; i. 632 = vi. 110; Orel. 2135; Wil. 48; *decurionum decreto*, etc.), and the magistrates or private persons executing or controlling the work, the place where and the time when it was erected, are added. On all these details the indexes, especially that of Wil. (ii. p. 675), give further information. The objects themselves which are offered or erected begin to be named only in the later period just as in the *tituli operum publicorum* ("*basim donum dant*," *C. I. L.*, i. 1167; "*signum basim*," *C. I. L.*, i. 1154; "*aram*," *C. I. L.*, i. 1468; Orel. 1466; Wil. 52; *C. I. L.*, i. 1109; Wil. 54); in the later period this custom becomes more frequent. It is hardly necessary to observe that all kinds of offerings have very frequently also been adorned with poetry; some of these *carmina dedicatoria* are given by Wil. 142–151.

3. Statues to mortals, whether living or after their death (but not on their tombs), with *honorary inscriptions* (*tituli honorarii*), were introduced into the Roman republic after the Greek model, and only at a comparatively late date. One of the oldest inscriptions of this class comes from Greek soil and is itself Greek in form (*C. I. L.*, i. 533; Wil. 649), "*Italicei L. Cornelium Scipionem* (*i. e.*, *Asiagenum*) *honoris caussa*," lost and of not quite certain reading, belonging to 561 A. U. C. (193 B. C.); the same form (in the accusative) appears in other (Latin or Latin and Greek) inscriptions from Greece (*C. I. L.*, i. 596 = iii. 532; Wil. 1103; *C. I. L.*, iii. 365; *Ephem. epigr.*, iv. 77; compare also *C. I. L.*, i. 587, 588; Orel. 3036). The same Greek form occurs also, curiously enough, in an honorary inscription of the age of Constantine (*C. I. L.*, i. 1708; Wil. 1227). But at an earlier date, at the end of the 5th century A. U. C., the noble house of the Scipios had already introduced the use of poetical *elogia*, in the ancient form of the *carmina triumphalia* in Saturnian verses (from the 6th century in elegiac distichs). As has been stated above, they were added to the short *tituli*, painted only with *minium* on the sarcophagi, giving the name of the deceased (in the nominative) and his curulian offices (exclusively), which were copied perhaps from the well-known *imagines* preserved in the *atrium* of the house (*C. I. L.*, i. 29 *sq.*; Orel. 550 *sq.*; Wil. 537 *sq.*; and elsewhere). They hold, by their contents, an intermediate place between the sepulchral inscriptions, to which they belong properly, and the honorary ones, and therefore are rightly styled *elogia*. What the Scipios did thus privately for themselves was in other cases done publicly at a period nearly as early. The first instance preserved of such a usage, of which Pliny the elder speaks (*Hist. Nat.*, xxxiv. § 17 *sq.*), is the celebrated *columna rostrata* of C. Duilius, of which only a copy exists, made in the time of the emperor Claudius (*C. I. L.*, i. 195 = vi. 1300; Orel. 549; Wil. 609). Then follow the *elogia* inscribed at the base of public works like the *Arcus Fabianus* (*C. I. L.*, i. 606, 607, and p. 278, elog. i.–iii. = vi. 1303, 1304; Wil. 610), or of statues by their descendants, as those belonging to a *sacrarium domus Augustæ* (*C. I. L.*, i. elog. iv.–vi. = *C. I. L.*, vi. 1310, 1311) and others belonging to men celebrated in politics or in letters, as Scipio, Hortensius, Cicero, etc., and found in Rome either on marble tablets (*C. I. L.*, i. vii.–xii. = *C. I. L.*, vi. 1312, 1279, 1283, 1271, 1273; Wil. 611–613) or on busts *C. I. L.*, i., xv.–xix. = *C. I. L.*, vi. 1327, 1295, 1320, 1309, 1325, 1326; Wil. 618–621; see also *C. I. L.*, i. 40 = vi. 1280; Wil. 1101; and *C. I. L.*, i. 631 = vi. 1278; i. 640 = vi. 1323; vi. 1321, 1322, where *T. Quincti* seems to be the nominative), and in divers other places (*C. I. L.*, i., xiii., xiv.; Wil. 614, 615). This custom seems to have been resumed by Augustus with a political and patriotic aim, praised by the poet Horace (*Od.*, iv. 8, 13, "*incisa notis marmora publicis, per quæ spiritus et vita redit bonis post mortem ducibus*"); for he adorned his *forum* with the statues of celebrated men from Æneas and Romulus downwards (*C. I. L.*, i., xxiv., xxv., xxvii., xxxii. = *C. I. L.*, vi. 1272, 1308, 1315, 1318; Wil. 625, 626, 627, 632), and other towns followed his example (so Pompeii, *C. I. L.*, i., xx., xxii. = Wil. 622, 623; Lavinium, *C. I. L.*, i., xxi., Wil. 617; Arretium, *C. I. L.*, i., xxiii., xxviii., xxix., xxx., xxxi., xxxiii., xxxiv. = Wil. 624, 625, 629–633). All these *elogia* are written in the nominative. In the same way in the colonies statues seem to have been erected to their founders or other eminent men, as in Aquileia (*C. I. L.*, i. 538 = v. 873, Wil. 650; compare also *C. I. L.*, v. 862; Orel. 3827) and Luna (*C. I. L.*, i. 539 = Wil. 651).

But along with this primitive and genuine form of the *titulus honorarius* another form of it, equivalent to the dedicatory inscription, with the name of the person honored in the dative, begins to prevail from the age of Sulla onwards. For the oldest examples of this form seem to be the inscriptions on statues dedicated to the dictator at Rome (*C. I. L.*, i. 584 = vi. 1297; Orel. 567; Wil. 1102*a*) and at other places (Caieta and Clusium, *C. I. L.*, i. 585, 586; Wil. 1102*b*, *c*), in which the whole set of honors and offices is not enumerated as in the *elogia*, but only the *honores præsentes;* compare also the inscription belonging to about the same date, of a *quæstor urbanus* (*C. I. L.*, i. 636). Within the Greek provinces also, at the same period, this form is adopted (*C. I. L.*, i. 595 = iii. 531; Henz. 5294; Wil. 1104). Similar dedications were offered to Pompey the Great (at Auximum and Clusium, *C. I. L.*, i. 615, 616; Orel. 574; Wil. 1107) and to his legate L. Afranius (at Bologna, but erected by the citizens of the Spanish colony Valentia, *C. I. L.*, i. 601; Henz. 5127; Wil. 1106). They are succeeded by the statues raised to Cæsar (at Bovianum, *C. I. L.*, i. 620; Orel. 582; Wil. 1108), and after his death, *iussu populi Romani*, in virtue of a special law, at Rome (*C. I. L.*, i. 626 = vi. 872; Orel. 586; Wil. 877). With him, as is well known, divine honors begin to be paid to the *princeps*, even during life. In this same form other historical persons of high merit also begin to be honored by posterity, as for example, Scipio the elder at Saguntum (*C. I. L.*, ii. 3836; Wil. 653), Marcellus, *Romanorum ensis*, at Nola (Mommsen, *Inscr. Neap.*, 1984; Henz. 5347), Marius at Cereatæ Marianæ, the place which bears his name (Mommsen, *Inscr. Neap.*, 4487; Wil. 654). Of statues erected by the community of a municipium to a private person, that of L. Popillius Flaccus at Ferentinum seems to be the oldest example (*C. I. L.*, i. 1164; Wil. 655, and his note). In Rome, Augustus and his successors in this way permitted the erection of statues, especially to *triumphatores*, in the new *fora*, including that of Augustus (*C. I. L.*, vi. 1386; Orel. 3187; Wil. 634; *C. I. L.*, vi. 1444; Henz. 5448; Wil. 635) and that of Trajan (*C. I. L.*, vi. 1377; Henz. 5478; Wil. 636; vi. 1549; Henz. 5477; Wil. 639; iv. 1549; Orel. 1386; Wil. 637; *C. I. L.*, 1565, 1566; Wil. 640); and this custom lasted to a late period (*C. I. L.*, vi. 1599; Henz. 3574; Wil. 638), as is shown by the statues of Symmachus the orator (*C. I. L.*, vi. 1698, 1699; Orel. 1186, 1187; Wil. 641), Claudian the poet (*C. I. L.*, vi. 1710; Orel. 1182; Wil. 642), Nicomachus Flavianus (*C. I. L.*, vi. 1782, 1783; Orel. 1188; Henz. 5593; Wil. 645, 645*a*), and many other eminent men down to Stilicho (*C. I. L.*, vi. 1730, 1731; Orel. 1133, 1134; Wil. 648, 648*a*), who died in the year 408. In similar forms are conceived the exceedingly numerous dedications to the emperors and their families, in which the names and titles, according to the different historical periods, are exhibited, in the main with the greatest regularity. They are specified in detailed indexes by Henzen and Wilmanns, as well as in each volume of the *Corpus*. In the provinces, of course, the usages of the capital were speedily imitated. Perhaps the oldest example of a *titulus honorarius* in the form of an *elogium* (but in the dative), with the full *cursus honorum* of the person honored, is a *bilinguis* from Athens, of the Augustan age (*C. I. L.*, iii. 551; Henz. 6456*a*; Wil. 1122); the honors are here enumerated in chronological order, beginning with the lowest; in other instances the highest is placed first, and the others follow in order.[1] In the older examples the formula "*honoris causa*," or *virtutis ergo* (*Hermes*, vol. vi., 1871, p. 6), is added at the end, as in an inscription of Mytilene belonging to the consul of the year 723 A. U. C., *i. e.* 31 B. C. (*C. I. L.*, iii. 455; Orel. 4111; Wil. 1104*b*); the same, abbreviated (*h. c.*), occurs on an inscription of about the same age from Cirta in Africa (*C. I. L.*, viii. 7099; Wil. 2384). Shortly afterwards the honor of a statue became as common in the Roman *municipia* as it was in Athens and other Greek cities in the later period. Each province furnishes numerous examples, partly with peculiar formulæ, on which the indexes of Wilmanns (p. 673, 696 *sq.*) may be consulted. Special mention may be made of the numerous honorary inscriptions belonging to aurigæ, *histriones*, and *gladiatores;* for those found in Rome see *C. I. L.*, vi. 10044–10210.

---

[1] This observation, applied to a large number of monuments, gave rise to many of the splendid epigraphical labors of Borghesi (see *e. g.*, his dissertation upon the inscription of the consul L. Burbuleius, *Œuvres*, iv. p. 103 *sq.*).

He who erects a temple or a public building, or constructs a road, a bridge, an aqueduct, or the like, by inscribing his name on the work, honors himself, and, as permission to do so has to be given by the public authorities, is also honored by the community. Therefore the *tituli operum publicorum*, though in form only short official statements (at least in the older period) of the origin of the work, without any further indications as to its character and purpose, partake of the style of the older honorary inscriptions. Of the ancient and almost universally employed method of erecting public buildings by means of the *locatio censoria* one monument has preserved some traces (*Ephem. epigr.*, ii. 199). The oldest instance of this class is that commemorating the restoration of the temple of the Capitoline Jupiter, begun, after its destruction by fire in the year 671 (83 B. C.), by Sulla and continued five years later by the well-known orator and poet Q. Lutatius Catulus, but completed only about twenty years afterwards. Here, after the name of Catulus in the nominative and the indication of the single parts of the building (as, for example, *substructionem et tabularium*) follows the solemn formula *de s(enati) s(ententia) faciundum coeravit eidemque probavit* (*C. I. L.*, i. 592 = vi. 1314; Orel. 31, 3267; Wil. 700). With the same formula the prætor M. Calpurnius Piso Frugi (of about the same period) dedicated an unknown building (*C. I. L.*, i. 594 = vi. 1275), restored afterwards by Trajan. On a work executed by the *collegium tribunorum plebis* (*C. I. L.*, i. 593 = vi. 1299; Wil. 787), perhaps the public streets within the town, the sum employed for it is also inscribed. Precisely similar is the oldest inscription of one of the bridges of Rome, the *ponte dei quattro capi*, still preserved, though partly restored, on its original site, which commemorates its builder, the tribune of the year 692 (62 B. C.), L. Fabricius (*C. I. L.*, i. 600 = vi. 1305; Orel. 50; Wil. 788); it was restored by the consuls of the year 733 (21 B. C.).[1] On privately erected buildings the founder after his name puts a simple *fecit* (as also on sepulchral inscriptions); so, possibly, did Pompey, when he dedicated his theatre as a temple of Venus Victrix and, on Cicero's clever advice, as Varro and Tiro had it from Cicero himself, inscribed on it COS'TERT (not *tertium* or *tertio*) (see Gellius, *Noct. Att.*, x. 1). So Agrippa, when he dedicated his Pantheon in the year 727 (27 B. C.), inscribed on it only the words *M. Agrippa L. f. cos. tertium fecit* (*C. I. L.*, vi. 896; Orel. 34; Wil. 731), as all who visit the Eternal City know. Of municipal examples it will be sufficient to name those of the majestic temple of Cora (*C. I. L.*, i. 1149–1150; Wil. 722, 723), of Ferentinum, with the measurements of the foundation (*C. I. L.*, i. 1161–1163; Wil. 708), of the walls and towers at Æclanum (*C. I. L.*, i. 1230; Orel. 566; Henz. 6583; Wil. 699), of the theatre, amphitheatre, baths, and other structures at Pompeii (*C. I. L.*, i. 1246, 1247, 1251, 1252; Orel. 2416, 3294; Henz. 6153; Wil. 730, 1899–1901). At Alatrium a munificent citizen gives an enumeration of a number of works executed by him in the period of the Gracchi, in his native town ("*hæc quæ infera scripta sunt de senatu sententia facienda coiravit*" (*C. I. L.*, i. 1166; Orel. 3892; Wil. 706); and, more than a century later, the same is done at Cartima, a small Spanish town near Malaga, by a rich woman (*C. I. L.*, ii. 1956; Wil. 746). Military works, executed by soldiers, especially frequent in the Danubian provinces, Africa, Germany, and Britain, give, in this way, manifold and circumstantial information as to the military administration of the Romans. On a column found near the bridge over the Minho at Aquæ Flaviæ, the modern Chaves in northern Portugal, ten communities inscribed their names, probably as contributors to the work, with those of the emperors (Vespasian and his sons), the imperial legate of the province, the legate of the legion stationed in Spain, the imperial *procurator*, and the name of the legion itself (*C. I. L.*, ii. 2477; Wil. 803); and similarly, with the name of Trajan, on the famous bridge over the Tagus at Alcántara, in Spanish Estremadura, the names of the *municipia provinciæ Lusitaniæ stipe conlata quæ opus pontis perfecerunt* are inscribed (*C. I. L.*, ii. 759–762; Orel. 161, 162; Wil. 804).

As in some of the already-mentioned inscriptions of public works the measurements of the work to which they refer (especially, as may be supposed, in the case of works of great extent, such as walls of towns or lines of fortification, like the walls of Hadrian and Antoninus Pius in Britain) are indicated, so it early became a custom in the Roman Republic to note on *milestones* the name of the founder of the road and, especially at the extremities of it and near large towns, the distances. So in the *val di Diana* in Lucania P. Popilius Lænas, the consul of the year 622 (132 B. C.), at the end of a road built by him, set up the *miliarium Popilianum* (*C. I. L.*, i. 551; Orel. 3308; Wil. 797), which is a general *elogium* to himself, in which he speaks in the first person (*viam fecei ab Regio ad Capuam*, etc.). One of the single *miliaria* set up by him is also preserved (*C. I. L.*, i. 550; Henz. 7174*d*; Wil. 808), which contains only his name and the number of miles. In the same brief style are conceived the other not very frequent republican *miliaria* found in Italy (*C. I. L.*, i. 535–537; Henz. 5348; Wil. 567; *C. I. L.*, i. 540; Henz. 5350, 6226; Wil. 807; *C. I. L.*, i. 558, 559; Henz. 5353; Wil. 808; *C. I. L.*, i. 561; Henz. 5180; Wil. 811; *C. I. L.*, i. 633; Wil. 812) down to the time of Augustus (Mommsen, *I. N.*, 6244; Wil. 813), and also the even more rare specimens from the provinces (from Asia—*C. I. L.*, i. 557 = iii. 479, Wil. 826, *C. I. L.*, i. 622 = iii. 462, Wil. 827; from Spain—*C. I. L.*, i. 1484–1486 = ii. 4920–4925, 4956, Wil. 828, 829). Augustus inscribed on each milestone on his road across Spain "*a Bæte et Jano Augusto ad Oceanum* (*e. g.*, *C. I. L.*, ii. 4701; Wil. 832), Claudius on those of a road in Upper Italy founded by his father Drusus "*viam Claudiam Augustam quam Drusus pater Alpibus bello patefactis derexserat munit ab Altino* (or *a flumine Pado*) *ad flumen Danuvium*" (*C. I. L.*, v. 8002, 8003; Orel. 648, 708; Henz. 5400; Wil. 818). The later milestones vary greatly in form, but all contain most precious and not yet nearly exhausted materials for ancient geography and topography; in the volumes of the *Corpus* they are taken together under the special head *viæ publicæ* (and here and there *privatæ*) at the end of each chapter.

A similar character, resulting from the combination of a mere authentic record with the peculiar form of the honorary inscription, belongs to the kindred classes of *inscriptions of the aqueducts* and of the different *boundary-stones*. The aqueducts of Rome are known to have their origin in remote antiquity; but no inscriptions belonging to them, so far as has been as yet discovered, go farther back than to the age of Augustus.[2] The large dedicatory inscriptions of the celebrated aqueducts of Rome (as the Aquæ Marcia, Tepula, and Julia, *C. I. L.*, vi. 1244–1246, Orel. 51–53, Wil. 765; the Virgo, *C. I. L.*, vi. 1252, Orel. 703, Wil. 763; the Claudia, etc., *C. I. L.*, vi. 1256–1258, Orel, 54–56, Wil. 764) have quite the character of honorary inscriptions, while the various *cippi terminales*, which mark the ground belonging to the aqueduct, show the greatest analogy to the milestones (*e. g.*, *C. I. L.*, vi. 1243*a–g*; Henz. 6635, 6636; Wil. 775–779). The other Italian and provincial varieties cannot be specified here. Of boundary-stones, or *cippi terminales*, some very ancient specimens have been preserved. To the age preceding the Second Punic War belong two, found at Venusia, and erected by municipal magistrates (*C. I. L.*, i. 185, 186; Orel. 3527, 3528; Wil. 863); they give a short relation of a decree, by which certain localities were declared to be sacred or public ("*aut sacrom aut poublicom locom ese*"). Then follow the *cippi Gracchani*, by which Gaius Gracchus and his two colleagues, as *tres viri agris iudicandis adsignandis*, measured the *ager Campanus*, for its division among the plebs. They contain the names of the *tres viri* in the nominative, and in addition, on the top, the lines and angles of the *cardo* and *decumanus*, according to the rules of the *agrimensores*, or the boundary lines between the *ager publicus* and *privatus* (*C. I. L.*, i. 552–556; Henz. 6464; Wil. 859–861). From the age of Sulla we still have various boundary-stones giving the line of demarcation between different communities (between Fanum and Pisaurum—*C. I. L.*, i. 583, Orel. 570, Wil. 861; between Ateste, Vicetia, and Patavium—*C. I. L.*, i. 547–549, Orel. 3110, Henz. 5114, 5115, Wil. 865, 866). To the town of Rome belong the *termini ripæ Tiberis* (*C. I. L.*, i. 608–614 = vi. 1234*a–l*), beginning in the Augustan age, and the *termini* of the *pomœrium* of Claudius and Vespasian as censors, and of the *collegium augurum* under Hadrian (*C. I. L.*, vi. 1231–1233; Orel. 710, 811; Wil. 843, 844), while others of the consuls of the year 4 A. D. (*C. I. L.*, vi. 1263; Orel. 3260; Wil. 856), of Augustus (*C. I. L.*, vi. 1265; Henz. 6455; Wil. 852), etc., show the boundary between the *ager publicus* and *privatus*. With similar objects boundary-stones were erected by the emperors, or, under their authority, by magistrates, mostly military, in the rest of Italy also (as in Capua—Mommsen, *I. N.* 3590, Orel. 3683, Wil. 858; at Pompeii—*I. N.* 2314, Wil. 864) and in the provinces as in Syria—*C. I. L.*, iii. 183; in Macedonia—*C. I. L.*, iii. 594; in Dalmatia—*C. I. L.*, iii.

---

[1] The character of an *elogium* is assumed in a special way by the inscriptions on triumphal arches, such as that of Augustus on the arch of Susa in Piedmont, dating from the year 745 (9 B. C.) (*C. I. L.*, v. 7231; Orel. 626), and the similar one on the *tropæa Augusti* (*la Turbia*) (*C. I. L.*, v. 7817) of the year 747 (7 B. C.), which Pliny also (*Hist. Nat.*, iii. § 136) records, and those of the other emperors at Rome, of which only that of Claudius, the conqueror of Britain (*C. I. L.*, vi. 920, 921; Orel. 715; Wil. 899), with the statues of himself and his family, need be mentioned.

[2] See the recent important work of R. Lanciani, *Commentari di Frontino intorno le acque e gli acquedotti*, etc., Rome, 1880.

2883; in Africa—*C. I. L.*, viii. 7084–90, 8211, 8268, 10803, 10838, Wil. 869, 870; in Spain—*C. I. L.*, ii. 2349, 2916, Wil. 871—where the *pratum* of a legion is divided from the territory of a *municipium*; in Gaul—Wil. 867; in Germany, in the column lately found at Miltenberg on the Main, *Bonner Jahrbücher*, vol. lxiv., 1878, p. 46, etc.). The recent attempt to combine under some boundary system the numerous stones found in Britain on military buildings, as on the wall of Hadrian and in divers *castra*, which indicate the *centuriæ* of legions and cohorts employed in the work and its measurements as executed by them, has been finally refuted by Mr. Clayton (in the *Archælogia Æliana*, 1880). Private grounds (*pedaturæ*) were unfrequently marked off by terminal *cippi*. To this class of *tituli* must be added also the curious inscriptions incised upon the steps of Roman circuses, theatres, and amphitheatres (see Hübner, *Annali dell' Instituto archeologico*, vol. xxviii., 1856, p. 52 *sq.*, and vol. xxxi., 1859, p. 122 *sq.*), as, for instance, upon those of the Coliseo at Rome (*C. I. L.*, vi. 1796, 1–37; compare R. Lanciani, *Bullettino archeologico municipale*, 1881).

4. We now come to the last class of *tituli*, viz., those which in the *Corpus* are arranged, at the end of each volume, under the head of *Instrumentum*. By this very comprehensive term are designated objects which vary greatly among themselves, but which are of such a character as not to fall within any of the classes of *tituli* described before, or the class of the *instrumenta* in the proper sense of that word,—the laws, etc. The *tituli* of the *instrumentum* embrace movable objects, destined for public and private use, and illustrate almost every side of the life of the ancient Romans. As systematic treatment of them is hardly possible, a simple enumeration only of their different classes can be given without citing special examples. The first species of them is metrological, comprehending the inscriptions on measures and weights. The gold and silver plate used in the best Roman houses was also always marked with a note of its weight,— as is seen, for instance, on the different objects belonging to the Hildesheim find (see *Hermes*, iii., 1868, p. 469 *sq.*; *Philologus*, xxviii., 1869, p. 369), the Corbridge *lanx* in Northumberland House (*C. I. L.*, vii. 1268), and many others. A second species is formed by the *tesseræ*, tokens or marks, mostly in bronze, bone, and ivory, but also earthen, of which the most interesting are the so-called *tesseræ gladiatoriæ*, little staves of bone with holes at the top, and with names of slaves or freedmen and consular dates upon them, the relation of which to the *munera gladiatoria* is by no means certain (see *C. I. L.*, i. 717 *sq.*, and Hübner, *Monatsberichte der Berl. Akad. der Wissenschaften*, 1867, p. 747 *sq.*, *Revue archéologique*, vol. xvi., 1868, p. 469 *sq.*, and *Ephem.*, iii. 203). The other circular *tesseræ* of ivory or bone, with emblems and short inscriptions, partly Greek and Latin, may with more confidence be attributed to the *ludi scænici* (see Henzen, *Annali dell' Instituto Archeologico*, vol. xx., 1848, p. 273 *sq.*, and vol. xxii., 1850, p. 357 *sq.*) and to other *ludi*; but the uses of many of them remain very uncertain. A third species is that of inscriptions carved, inscribed, painted, or stamped upon various materials, raw or manufactured, for trade or household use. Such are, to begin with the most solid and heavy, the inscriptions carved or painted on masses of stone, mostly columns, in the quarries, and preserved either on the rocks themselves in the quarries or on the roughly hewn blocks transported to the Roman *emporium* on the Tiber bank. Curious specimens of the first kind are preserved in Lebanon, and in the north of England, near Hadrian's Wall and elsewhere; on the second may be consulted a learned treatise by Padre L. Bruzza ("Iscrizioni dei marmi grezzi," in the *Annali dell' Instituto archeologico*, vol. xlii., 1870, p. 106–204). Of a kindred character are the inscriptions mostly stamped or engraved in the mould, of pigs of silver, bronze, and lead (and pewter), found in the Roman mines in Spain and England (see Hübner, "Römische Bleigruben in Britannien," in *Rheinisches Museum für Philologie*, vol. xi., 1857, p. 347, *sq.*, and *C. I. L.*, vii. p. 220 *sq.*; A. Way, *Archæological Journal*, vol. xvi., 1859, p. 23, and vol. xxiii., 1866, p. 63). A fourth species of *tituli* of this class is strictly related to the military institutions of the Roman empire. Many of the weapons are marked with the names of the bearer and of the military corps to which he belonged,—so, for example, the buckles of their shields (see Hübner, "Römische Schildbuckel," in *Archäologische-epigraphische Mittheilungen aus Oesterreich*, vol. ii., 1878, p. 105 *sq.*; by far the best extant specimen is the umbo of a legionary soldier of the eighth legion found in the Tyne near South Shields, *C. I. L.*, vii. 495), and sometimes the swords, as that of Tiberius from Mainz (now in the British Museum, see *Bonner Winckelmannsprogramm* of 1848). The leaden *glandes* used by the *funditores*, the slingers in the Roman army, bear curious historical inscriptions (see *C. I. L.*, i. 642 *sq.*, and, on the question of the authenticity of many of them, much discussed of late. Bergk, *Bonner Jahrbücher*, vols. lv., lvi., 1875, p. 1 *sq.*, and Zangemeister, *Monatsberichte der Berliner Akademie der Wissenschaften*, 1875, p. 465, 1876, p. 65 *sq.*; *Bullettino dell' Instituto archeologico*, 1877, p. 172, 1879, p. 190 *sq.*). Special mention must be made also of the leaden seals or marks, evidently of military origin (perhaps to be borne by the soldiers as a countersign), which have been found in many parts of England, but nowhere else as yet (*C. I. L.*, vii. 1269; *Ephem. epigr.*, iii. p. 144, 318, iv. p. 209). Of the highest interest are the manifold productions of the Roman tile and brick kilns. Next to the tiles with consular dates made at Veleia (*C. I. L.*, i. 777 foll.), those signed with the name of legions or other military corps, and employed to the various military buildings of these, are especially worthy of mention; they form an important chapter in every geographical part of the *Corpus*. But private persons, too, especially the rich landed proprietors, and afterwards the emperors and their kinsmen, kept large *figulinæ*, and their manufactures—tiles of every description and other earthenware—were spread over the Roman empire. The different sorts of earthen vessels and lamps, the fragments of which are found in great quantities wherever Roman settlements occurred, are arranged at the end of each volume of the *Corpus*. But a scientific inquiry into their origin, age, and employment, difficult on account of the enormous and always increasing mass of the extant remains, has not yet been undertaken, the small works of Froehner (*Inscriptiones terræ coctæ vasorum*, Göttingen, 1858) and Schuermans (*Sigles figulins*, Brussels, 1867) being by no means satisfactory. On Roman lamps and their inscriptions the accurate catalogue of the Vienna collection by Kenner ("Die Antiken Thonlampen des K. K. Müns- und Antiken-Cabinetes, und der K. K. Ambraser Sammlung," in the *Archiv für Kunde österreichischer Geschichtsquellen*, vol. xx., Vienna, 1858) may be consulted with advantage. But a good beginning to a thorough treatment of the question has been made by an accurate exploration of the chief deposit of those fragments, the *Monte testaccio* at Rome, by Dressel ("Ricerche sul Monte testaccio," in the *Annali dell' Instituto archeologico*, vol. i., 1878, p. 118–192). Inscriptions are found on various classes of vessels, painted (as the consular dates on the large *dolia* for wine, oil, etc., see Schöne, *C. I. L.*, iv. p. 171 *sq.*, and *Ephem. epigr.*, i. p. 160 *sq.*), stamped on the clay when still wet or in the mould, and scratched in the clay when dry, like those on the walls of ancient buildings in Pompeii, Rome, and other places of antiquity. Like the corresponding Greek ware, they contain chiefly names of the makers or the merchants or the owners, and can be treated in a satisfactory manner only when brought together in one large collection, inasmuch as, besides being made in many local potteries, they were exported principally from some places in Italy (*e. g.*, Arezzo) and Spain, in nearly every direction throughout northern and western Europe, the countries outside the Roman frontiers not excluded. Vessels and utensils of glass and of metal (gold, silver, and especially bronze) were also exported from Italy on a large scale, as is being more and more readily recognized even by those antiquaries who formerly were wont to assume a local origin for all bronze finds made in the north of Europe. These utensils, ornaments, and other objects made of precious metals (such as cups, spoons, mirrors, *fibulæ*, rings, gems), not unfrequently bear Latin inscriptions. On the very ancient silver and bronze caskets, for holding valuable articles of the female toilet, which have been found at Præneste, are inscribed, in addition to the names of the artist and of the donor, occurring once, the names of the persons in the mythical representations engraved upon them (*C. I. L.*, i. 54–60, 1500, 1501; Jordan, *Kritische Beiträge zur Geschichte der lateinischen Sprache*, Berlin, 1879, p. 3 *sq.*). In the ancient well of the *Aquæ Apollinares*, near Vicarello in Tuscany, three silver cups have been found with circumstantial itineraries "*a Gades* (sic) *usque Romam*" engraved upon them, evidently gifts to the divinity of the bath for recovered health presented by travellers from the remote city named (Henzen 5210). Similar is the Rudge Cup, found in Wiltshire and preserved at Alnwick Castle, which contains, engraved in bronze, an itinerary along some Roman stations in the north of England (*C. I. L.*, vii. 1291). The inscriptions of the Hildesheim silver find and others of a similar character have been already mentioned; and many examples might be enumerated besides. On the ancient glass ware and the inscriptions on it the splendid works of Deville (*Histoire de l'art de la verrerie dans l'antiquité*, Paris, 1873) and Froehner (*La verrerie antique, description de la collection Charvet*, Paris, 1879) may be consulted; on the Christian glasses that of Garrucci (*Vetri ornati di figure in oro trovati nei cimiteri dei cristiani primitivi di Roma*, Rome, 1858). The last species of *tituli* is formed by the stamps themselves

with which the inscriptions on many of the objects already named are produced. They are mostly of bronze and contain names; but it is not easy to say what sort of objects were marked with them, as scarcely any article stamped with a still existing stamp has been found. Amongst the materials stamped leather also is to be mentioned. One class only of stamps differs widely from the rest,—the oculists' stamps, engraved mostly on steatite (or similar stones), and containing remedies against diseases of the eyes, to be stamped on the glass bowls in which such remedies were sold, or on the medicaments themselves (see Grotefend, *Die Stempel der römischen Augenärzte gesammelt und erklärt*, Göttingen, 1867; since its publication many new examples have come to light).

IV. The other great class of inscriptions above referred to, the *instrumenta* or *leges*, the laws, deeds, etc., preserved generally on metal and stone, from the nature of the case have to be considered chiefly with regard to their contents; their form is not regulated by such constant rules as that of the *tituli*, so far as may be inferred from the state of completeness in which they have been preserved. The rules for each special class, therefore, though, generally speaking, maintained—as was to be expected of Roman institutions—with remarkable steadiness from the earliest times down to a late period, must be based upon a comprehensive view of all the examples, including those preserved by ancient writers, and not in the monumental form. These documents are, as a rule, incised on bronze plates (only some private acts are preserved on wood and lead), and therefore have their peculiar form of writing, abbreviation, interpunction, etc., as has been already explained. A complete collection of these monuments, although projected by many workers in the field of Roman jurisprudence from Antonius Augustinus downward, has not yet been made. The older Roman laws are now collected, in trustworthy texts, in the *Corpus*, vol. i.; of the documents belonging to the later period a very comprehensive though not quite complete *sylloge* is given in the late lamented C. G. Bruns's *Fontes juris Romani antiqui* (Tübingen, 4th ed., 1879).

1. Among the earliest occasions for committing to writing agreements, which may be supposed to have been originally verbal only, must certainly be reckoned international transactions (*leges fæderis* or *fædera*). At the head of the prose records written in the Latin language we find the treaties of alliance of Tullus Hostilius with the Sabini (Dionysius Halic., iii. 33), of Servius Tullius with the Latini (Dionysius, iv. 26; Festus, p. 169; this was, partly, at the same time, as will afterwards appear, the oldest document of the sacred class), of the second Tarquinius with Gabii (Dionysius, iv. 58; Festus, *epit.*, p. 56). They are followed, in the oldest republican period, by the celebrated *fœdera* with Carthage, so much discussed of late; by the pacts of Sp. Cassius Vecellinus with the Latini of the year 261 (493 B. C), which Cicero seems to have seen still in the *forum* behind the *rostra*, written on a bronze column (*Pro Balbo*, 23, 53; see also Livy, ii. 33; Festus, p. 166; and Mommsen's *Römische Forschungen*, ii. p. 153 *sq.*); and by the *fœdus Ardeatinum* of 310 (414 B. C.) mentioned by Livy (iv. 7). Of all these documents nothing has been preserved in an authentic form save some few words quoted from them by the ancient grammarians. Of one *fœdus* only is there a fragment still in existence, relating to the Oscan *civitas libera* Bantia (*C. I. L.*, i. 197); it was drawn up between 621 and 631 (133 and 123 B. C.), and contains the *clausula* of the *fœdus*, which was written in Latin and in Oscan. On account of this peculiar circumstance, the document gave occasion to Klenze, and afterwards to Mommsen, to resume (for the sake of Roman jurisprudence, in the first instance) inquiry into the Oscan and other Italian dialects. Some other Roman *fœdera* are preserved only in Greek, *e.g.*, that with the Jews of the year 594 (160 B. C.) (Josephus, *Ant.*, xii. 6, 10). Some others, made with the same nation between 610 and 615 (144 and 139 B. C.) (Jos., *Ant.*, xiii. 5, 6, and 7, 8), are mentioned in an abridged form only (see Mendelssohn, "Senati consulta Romanorum quæ sunt in Josephi antiquitatibus," etc., in the *Acta Societ. Philol. Lips.*, vol. v., 1875, p. 87 *sq.*, and compare *Rheinisches Museum für Philologie*, vol. xxx., 1875, p. 118 *sq.*, xxxii., 1877, p. 249; Ritschl's *Opuscula*, vol. v. p. 99 *sq.*; Mommsen, *Hermes*, vol. ix., 1874, p. 281 *sq.;* Niese, *Hermes*, vol. xi., 1876, p. 466 *sq.*), or given in that of a *senatus consultum*, to which they must formally be ascribed. Amongst the *fœdera* may be reckoned also the curious oath, sworn, perhaps, according to a general rule obtaining for all *civitates fœderatæ*, by the citizens of a Lusitanian *oppidum*, Aritium, to Gaius Cæsar on his accession to the throne in A. D. 37 (*C. I. L.*, ii. 172; Wil. 2839).

Closely related to the *fœdera* are the pacts between communities and private individuals, respecting *patronatus* or *hospitium* (*tabulæ patronatus et hospitii*, also, when in small portable form, *tesseræ hospitales*), of which many specimens from the end of the republic down to a late period of the empire have been preserved (see Gazzera, *Memorie dell' Academia di Torino*, vol. xxxv., 1831, p. 1 *sq.*, and Mommsen, *Römische Forschungen*, i. p. 341 *sq.*). There is at present no complete collection of these; for since Gazzera's time many new ones have been found. Of the numerous examples scattered through the different volumes of the *Corpus* may be quoted the *tessera Fundana*, containing the pact of hospitality between the community of Fundi and a certain Ti. Claudius (who cannot, with certainty, be identified), the oldest hitherto known, in the form of a bronze fish (*C. I. L.*, i. 532; Henz. 7000; Wil. 2849); the *tabula* of the *pagus Gurzensium* in Africa, delivering the patronate to L. Domitius Ahenobarbus, Nero's grandfather, in 742 (12 B. C.), in the afterwards solemn form of a *tabella fastigata*, to be fixed in the *atrium* of the person honored (Orel. 3693; Wil. 2850); that of the *civitas Palantina* with a *peregrinus* named *Acces Licirini* of the year 752 (2 B. C.) (*Ephem. epigr.*, i. 141; *Hermes*, v., 1871, p. 371 *sq.*); that of *Lacilbula*, in Spain, with one Q. Marius Balbus, of 5 A. D. (*C. I. L.*, ii. 1393); that of the *Bocchoritani* on the island of Majorca, of 6 A. D. (*C. I. L.*, ii. 3695; Wil. 2851); the four relating to C. Silius Aviola, dating from 27 to 28 A. D., all found at Brescia (*C. I. L.*, v. 4919–4922); that of the *colonia Julia Aug. legionis* vii. *Tupusuctu*, in Africa, with the imperial legate Q. Julius Secundus, of 55 A. D. (*C. I. L.*, viii. 8837; Wil. 2851); that of two *gentilitates*, the *Desonci* and *Tridiavi*, of the *gens* of the *Zœlæ*, in Spain, now in the Museum of Berlin, which contains an older act of the year 27, and another more recent of the year 127 A. D. (*C. I. L.*, ii. 2633; Orel. 156); that of the *respublica Pompelonensis* (Pampluna in Spain) of 185 A. D. (*C. I. L.*, ii. 2960; Wil. 2854); that of the *Segisamonenses*, in Spain, of 239 A. D., now in the museum at Burgos (*Ephem. epigr.*, ii. 322); that of the *fabri subidiani* (*i.e.*, subædiani, qui sub æde consistunt) of Cordova, of 348 A. D (*C. I. L.*, ii. 2211; Wil. 2861); and, in addition to many others, those found together at Rome, on the site of the palace of Q. Aradius Valerius Proculus, and belonging to him and other members of his family, from divers African cities, and executed in 321 and 322 A. D. (*C. I. L.*, vi. 1684–88; Orel. 1079, 3058).

2. Hardly inferior in antiquity, and of superior value, are the remains of laws in the stricter sense of the word (*leges* and *plebiscita*), preserved to us in the originals, although unfortunately only in fragments more or less extensive. Of those laws the oldest and most important are the *lex Acilia* (for so it is in all probability to be styled) *repetundarum* of the year 631 (*C. I. L.*, i. 198), which is incised on a bronze table about 2 metres broad, in 90 lines of about 200 to 240 letters each, and therefore extremely inconvenient to read, and the *lex agraria* of 643 (111 B. C.), written on the reverse of the table of the Acilia, abrogated shortly afterwards (*C. I. L.*, i. 200); this is the third of the celebrated laws of C. Gracchus bearing upon the division of public lands. Then follow the *lex Cornelia de viginti quæstoribus*, a fragment of Sulla's legislation, the eighth table only, of the whole set, being preserved (*C. I. L.*, i. 202); the *plebiscitum de Thermensibus*, on the autonomy of Termessus in Pisidia, proposed by the *tribuni plebis*, in 682 (72 B. C.), one of four or five large bronze plates (*C. I. L.*, i. 204); the *lex Rubria de civitate Galliæ cisalpinæ* of 705 (49 B. C.), written in a new and more convenient form (belonging as it does to Cæsar's legislation), in two columns, with numbered divisions, being the fourth out of an unknown number of plates (*C. I. L.*, i. 205); the *lex Julia municipalis*, or, from the place where it was found, the *tabulæ Heracleenses* of 709 (45 B. C.), written on the reverse of the much older Greek law of that community, preserved partly at Naples, partly in the British Museum (*C. I. L.*, i. 206), also a fragment of Cæsar's general municipal institutions; it contains a curious passage relating to the public promulgation of laws (v. 15). These are the laws of the Roman republic preserved in important fragments; some minor ones (brought together in *C. I. L.*, i. 207–211) may be left out of account here. In the imperial age, laws in general were replaced by *senatus consulta*, or by imperial decrees. It was also in the form of a *senatus consultum* that the *leges de imperio*, on the accession of the emperors, seem to have been promulgated. An example of such a law, preserved in part on a bronze tablet found at Rome, is the *lex de imperio Vespasiani* (*C. I. L.*, vi., 930; Orel. vol. i. p. 567). There is, besides, one special category of imperial constitutions which continued to be named *leges*, viz., the constitutions given by the emperors to the divers classes of *civitates*, based upon the ancient traditional rules of government applied to Rome itself as well as to the *coloniæ* and *municipia*. Of this sort of *leges* some very valuable specimens have come from Spanish soil, viz., the *lex coloniæ Juliæ Genetivæ Urbanorum sive Ursonis* (now Osuna), given to that colony by Cæsar in 710 (44 B. C.), but incised, with some

alterations, in the time of Vespasian, of which three bronze tables out of a much larger number remain (Hübner and Mommsen, *Ephem. epigr.*, ii. p. 150 *sq.* and 221 *sq.*); the *lex Salpensana* and the *lex Malacitana*, given to these two *municipia* by Domitian, between 81 and 84 A. D., each on a large bronze plate, written respectively in two and in five columns, with the single chapters numbered and rubricated (*C. I. L.*, ii. 1963, 1964, compare Mommsen, "Die Stadtrechte der ateinischen Gemeinden Salpensa und Malacca in der Provinz Bætica," in the *Abhandlungen der sächsischen Gesellschaft der Wissenschaften, philol.-histor. Classe*, vol. iii., 1857, p. 363 *sq.*); the *lex metalli Vipascensis*, given, with all probability, by one of the three Flavii, as a constitution to a mining district of southern Portugal, one bronze plate numbered iii.—three or more, therefore, being lost (see Hübner, *Ephem. epigr.*, iii. p. 165 *sq.*, and, for a popular account, the *Deutsche Rundschau*, August, 1877, p. 196 *sq.*). The so-called military diplomas, although in certain respects nearly related to the *leges* of the later period, are better placed along with the imperial decrees.

3. A third species of official documents is formed by decrees of the senate of Rome, of the analogous corporations in the *coloniæ* and *municipia*, and of the divers *collegia* and *sodalicia*, constituted, as a rule, after a similar fashion and debating in nearly the same way as the Roman and the municipal senates. The oldest Roman *senatus consulta* are those translated into the Greek language and containing treaties of alliance, as already mentioned. They are preserved either on monuments or by ancient authors, as Josephus:—*e.g.*, the fragment found at Delphi, from the year 568 (186 B. C.), and the *sc. Thisbæum*, from Thisbe in Bœotia, 584 (170 B. C.) (*Ephem. epigr.*, i. p. 278 *sq.*, ii. p. 102, and Joh. Schmidt, *Zeitschrift der Savigny-Stiftung*, vol. iii., 1881), those of 616, 619, 621, 649 (138–105 B. C.) (*C. I. Græc.*, 2905, 2908, ii. 2485, 2737; Le Bas and Waddington, vol. iii. p. 195–198; *Annali dell' Instituto*, vol. xix., 1847, p. 113; *Ephem. epigr.*, iv. p. 213 *sq.*), and those relating to the Jews, dating from 615, 621, and 710 (139, 133, and 44 B. C.) (Josephus, *Ant.*, xiii. 9, 2, xiv. 8, 5 and 10, 9). The two oldest *senatus consulta* written in Latin are also preserved in a more or less complete form only by ancient authors; they are the *sc. de philosophis et rhetoribus* of 593 (161 B. C.) (Gellius, *Noct. Att.*, xv. 11, 1) and that *de Hastis Martiis* of 655 (99 B. C.) (Gellius, iv. 6, 2). The only one belonging to the oldest period preserved in the original Latin form, of which only a part exists, together with the Greek translation, is the *sc. Lutatianum*, relating to Asclepiades of Clazomenæ and his companions, dating from 676 (77 B. C.) (*C. I. L.*, i. 203). The rest, belonging to the later epoch from Cicero downwards, about twenty in number, are mostly preserved only in an abridged form by ancient writers,—such as Cicero, Frontinus, Macrobius,—or in Justinian's *Digesta* (see Hübner, *De senatus populique Romani actis*, Leipsic, 1859, p. 66 *sq.*); a few exist, however, in a monumental form, complete or in fragments—as the two *sc.* on the *ludi sæculares*, dating from 17 B. C. and 47 A. D., preserved on a marble slab found at Rome (*C. I. L.*, vi. 877); the fragments of two *sc.* in honor of Germanicus and the younger Drusus, from Rome, on bronze tablets (*C. I. L.*, vi. 911–912; Henz. 5381–5282); the two *sc. Hosidianum* and *Volusianum*, containing regulations for the demolition and rebuilding of houses in Rome, incised on the same bronze plate, found at Herculaneum, dating from Nero's time, between 41 and 46 and from 56 A. D. (Orel. 3115; Mommsen, *Berichte der sächs. Gesellschaft der Wissenschaften, philol.-histor. Classe*, 1852, p. 272 *sq.*); and, of a later period, the *sc. Casianum* or *Nonianum* of 138 A. D., containing a market regulation for the *saltus Beguensis* in Africa, where it has been found preserved in two examples on stone slabs (*Ephem. epigr.*, ii. p. 271 *sq.*, not complete in Wil. 2838), and the fragment of that for Cyzicus, belonging to the reign of Antoninus Pius (*Ephem. epigr.*, iii. p. 156 *sq.*). There exists, besides, a chapter of a *sc.*, relating to the *collegia*, inserted in the decree of a *collegium* at Lanuvium, to be mentioned below. Of the municipal decrees, of which a greater number is preserved (see Hübner, *De sen. populique Rom. actis*, p. 71 *sq.*), only a few of the more important may be mentioned here:—the *lex Puteolana de parieti faciundo* of 649 (105 B. C.) (*C. I. L.*, i. 577; Orel. 3697; Wil. 697); the two *decreta* (or so-called *cenotaphia*) *Pisana* in honor of Lucius and Gaius Cæsar, the grandsons of Augustus, of 3 A. D. (Orel. 642, 643; Wil. 883); the *decretum Lanuvinum* of 133 A. D., containing the regulations of a *collegium funeraticium*, styled *collegium salutare Dianæ et Antinoi* (Or. 6086; Wil. 319); and the *decretum Tergestinum*, belonging to the time of Antoninus Pius (*C. I. L.*, v. 532; Henz. 7167; Wil. 693). There are, however, more than thirty others preserved, some of them, such as those from Naples, written in the Greek language. Of the third specialty, the *decreta collegiorum*, only the *lex collegii aquæ* of the first century (Marini, *Atti de' fratelli Arvali*, p. 70; Rudorff and Mommsen, *Zeitschrift für Rechtsgeschichte*, vol. xv., 1850, p. 203, 345 *sq.*), and the *lex collegii Æsculapii et Hygiæ*, of 153 (*C. I. L.*, vi. 10234; Orel. 2417; Wil. 320) need be mentioned here; many more exist. One of them, the *lex collegii Jovis Cerneni*, dating from 167 A. D., found at Alburnum major in Dacia, is preserved on the original *tabella cerata* on which it was written (*C. I. L.*, iii. p. 924; Henz. 6087; Wil. 321).

4. The fourth species of *instrumenta* are the decrees, sometimes in the form of letters, of Roman and municipal magistrates, and of the emperors and their functionaries, incised, as a rule, on bronze tablets. The oldest decree in the Latin language which has been preserved is that of L. Æmilius Paulus, when prætor in Hispania Bætica, dating from 189 B. C., for the Turris Lascutana in southern Spain (*C. I. L.*, ii. 5041; Wil. 2837); of the same date is a Greek one of Cn. Manlius, consul of the year 565, for the Heracleenses Cariæ (Le Bas and Waddington, n. 588). Then follow the famous *epistula consulum* (falsely styled commonly *senatus consultum*) *ad Teuranos de bacchanalibus*, dated 568 (186 B. C.) (*C. I. L.*, i. 196; the sentence of the two Minucii, the delegates of the senate, on a dispute concerning the boundaries between the Genuates and Viturii, 117 B. C. (*C. I. L.*, i. 199; Orel. 3121; Wil. 872); and the *epistula* of the prætor L. Cornelius (perhaps Sisenna), the prætor of 676 (78 B. C.) *ad Tiburtes* (*C. I. L.*, i. 201). These belong to the republican age. From the imperial period a great many more have come down to us of varying quality. Some of them are decrees or constitutions of the emperors themselves. Such are the decree of Augustus on the aqueduct of Venafrum (Henz. 6428; Wil. 784); that of Claudius, found in the Val di Nona, belonging to 46 A. D. (*C. I. L.*, v. 5050; Wil. 2842); of Vespasian for Sabora in Spain (*C. I. L.*, ii. 1423), and for the Vanacini in Corsica (Orel. 4031); of Domitian for Falerii (Orel. 3118); the epistles of Hadrian relating to Æzani in Phrygia, added to a Greek decree of Avidius Quietus (*C. I. L.*, iii. 355; Henz. 6955), and relating to Smyrna, in Greek, with a short one of Antoninus Pius, in Latin (*C. I. L.*, iii. 411; Orel. 3119); the decrees of Commodus relating to the *saltus Burunitanus* in Africa (Mommsen, *Hermes*, vol. xv., 1880, p. 358 *sq.*); of Severus and Caracalla for Tyra (Akerman in Mœsia), Latin and Greek (*C. I. L.*, iii. 781; Henz. 6429); of Valerian and Gallienus for Smyrna, also Latin and Greek (*C. I. L.*, iii. 412); of Diocletian *de pretiis rerum venalium*, containing a long list of prices for all kinds of merchandise, preserved in divers copies more or less complete, in Latin and Greek (*C. I. L.*, iii. p. 801 *sq.*; compare *Ephem. epigr.*, iv. p. 180, and, as similar monuments, the *lex portus* of Cirta, of 202 A. D., Wil. 2738, and the fragment of a regulation for the importation of wines into Rome, Henz. 5089, Wil. 2739); and some of the age of Constantine, as that relating to Hispellum in Umbria (Henz. 5580; Wil. 2843), that of Julian found at Amorgos (Henz. 6431), and some others, of which copies exist also in the juridical collections. Of two imperial rescripts of a still later age (413 A. D.), fragments of the originals, written on papyri, have been found in Egypt (see Mommsen and Jaffé, *Jahrbuch des gemeinen deutschen Rechts*, vol. vi., 1861, p. 398; Hänel, *Corpus legum*, p. 281). Imperial decrees, granting divers privileges to soldiers, are the *diplomata militaria* also, mentioned above, incised on two combined bronze tablets in the form of *diptycha*, of which about seventy examples have been brought together in the *Corpus* (vol. iii. p. 842 *sq.*); some specimens are given in Wil. 2862–2869 and in the *Ephem. epigr.* (vol. ii. p. 452 and vol. iv. p. 181 *sq.*) belonging to nearly all emperors from Claudius down to Diocletian. Though not a decree, yet as a publication going back directly to the emperor, and as being preserved in the monumental form, the speech of the emperor Claudius, delivered in the senate, relating to the Roman citizenship of the Gauls, of which Tacitus gives an abstract (*Ann.* xi. 23), ought also to be mentioned here; it was engraved on large bronze slabs by the public authority of Lugudunum (Lyons), where a large fragment of it is still preserved (Boissieu, *Inscriptions antiques de Lyon*, p. 132 *sq.*). Another sort of decrees, relating to a great variety of subjects, has to be mentioned, emanating, not directly from the emperors, but from their functionaries. Such are the decree of the proconsul L. Helvius Agrippa, of the year 68 A. D., on the boundaries of some tribes on the island of Sardinia (Wil. 872*a*); that of the prefect of Egypt, Tiberius Julius Alexander, written in Greek, of the same year (*C. I. Græc.*, 4957); that of C. Helvidius Priscus, on a similar question relating to Histonium, belonging perhaps to the end of the first century (Wil. 873); that of the legate of Trajan, C. Avidius Quietus, one of the friends of Plutarch, found at Delphi, in Greek and Latin (*C. I. L.*, iii. 567; Orel. 3671; Wil. 874); a rescript of Claudius Quartinus, perhaps the imperial legate of the Tarraconensis, of the year 119 A. D.,

found at Pampluna (*C. I. L.*, ii. 2959; Orel. 4032); the epistle of the *præfecti prætorio* to the magistrates of Sæpinum, of about 166–169 A. D. (Mommsen, *I. N.*, 4916; Wil. 2841); the decree of L. Novius Rufus, another legate of the Tarraconensis, who *ex tilia recitavit*, of 193 A. D. (*C. I. L.*, ii. 4125; Orel. 897; Wil. 876); the sentence of Alfenius Senecio, then subprefect of the *classis prætoria Misenensis*, belonging to the beginning of the third century, formerly existing at Naples (Mommsen, *I. N.*, 2646); and some others of the fourth and fifth centuries, not requiring specific mention here. Quite a collection of epistles of high Roman functionaries is found in the celebrated inscription of Thorigny (Mommsen, *Berichte der sächs. Gesellschaft der Wissenschaften*, 1852, p. 235 *sq.*). The letter of a provincial functionary, a priest of Gallia Narbonnensis, to the *fabri subædiani* of Narbonne, of the year 149, may also be mentioned (Henz. 7215; Wil. 696 *a*). To these must be added the *tabulæ alimentariæ*, relating to the well-known provision made by Trajan for the relief of distress among his subjects, such as that of the Ligures Bæbiani (Mommsen, *I. N.*, 1354; Wil. 2844) and that of Veleia near Parma (Wil. 2845); while evidence of similar institutions is furnished by inscriptions at Tarracina, at Sicca in Africa, and at Hispalis in Spain (Wil. 2846–48; *C. I. L.*, ii. 1174). At the close of this long list of official documents may be mentioned the *libellus* of the *procurator operum publicorum a columna divi Marci* of the year 193 (*C. I. L.*, vi. 1585; Orel. 39; Wil. 2840) and the *interlocutiones* of the *præfecti vigilum* on the lawsuit of the *fullones* of Rome, of 244 A. D., inscribed on an altar of Hercules (*C. I. L.*, vi. 266; Wil. 100). These documents form a most instructive class of *instrumenta*.

5. Many documents, as may be supposed, were connected with religious worship, public and private. The oldest *lex templi*, which continued in force until a comparatively late period, was the regulation given by Servius Tullius to the temple of Diana on the Aventine, after the conclusion of the federal pact with the Latini, noticed above. Mention is made of this ancient law as still in force in two later documents of a similar character, viz., the dedication of an altar to Augustus by the plebs of Narbo in southern France, of 764 A. D., but existing only, at Narbonne, in a copy, made perhaps in the 2d century (Orel. 2489; Wil. 104), and that of an altar of Jupiter, dedicated at Salonæ in Dalmatia in 137 A. D., still existing in part at Padua (*C. I. L.*, iii. 1933; Orel. 2490; Wil. 163). Another *lex fani* still existing is that of a temple of Jupiter Liber at Furfo, a *vicus* of southern Italy, of the year 696 (58 B. C.), but copied, in vernacular language, from an older original (*C. I. L.*, i. 603; Orel. 2488; Wil. 105; compare Jordan in *Hermes*, vol. vii., 1872, p. 201 *sq.*). The lists of objects belonging to some sanctuaries or to the ornaments of statues are curious, such as those of the *Diana Nemorensis* at Nemi (Henz., *Hermes*, vol. vi., 1871, p. 8 *sq.*), and of a statue of Isis in Spain (Hübner, *Hermes*, vol. i., 1866, p. 345 *sq.*; compare *C. I. L.*, ii. 2060, 3386, Orel. 2510, Wil. 210), and two *synopses* from a temple at Cirta in Africa (Wil. 2736, 2737). The *sortes* given by divinities may also be mentioned (see *C. I. L.*, i. p. 267 *sq.*; Wil. 2822). To a temple also, though in itself of a secular character, belonged a monument of the highest historical importance, viz., the *Index rerum a se gestarum*, incised on bronze slabs, copies of which Augustus ordered to be placed, in Latin and Greek, where required, in the numerous Augustea erected to himself in company with the Dea Roma. This is known as the *Monumentum Ancyranum*, because it is at Angora in Asia Minor that the best preserved copy of it, in Greek and Latin, exists; but fragments remain of other copies from other localities (see *C. I. L.*, iii. p. 779 *sq.*, and the special editions of Mommsen, Berlin, 1865, and Bergk, Göttingen, 1873). Among the inscriptions relating to sacred buildings must also be reckoned the numerous fragments of Roman calendars, or *fasti anni Juliani*, found at Rome and other places, which have been arranged and fully explained by Mommsen (*C. I. L.*, i. p. 293 *sq.*; compare *Ephem. epigr.*, i. p. 33, ii. p. 93, iii. p. 5, 85, iv. p. 1 *sq.*, and for those found in Rome, *C. I. L.*, vi. 2294–2306). Local, provincial, or municipal *kalendaria* have likewise been found (as the *feriale Cumanum*, *C. I. L.*, i. p. 310, and the *Capuanum*, Mommsen, *I. N.*, 3571). Many other large monumental inscriptions bear some relation, more or less strict, to sacred or public buildings. Along with the official calendar exhibited on the walls of the residence of the *pontifex maximus*, the list of the eponymous magistrates, inscribed by the order of Augustus on large marble slabs, was publicly shown,—the *fasti consulares*, the reconstruction and illustration of which formed the life-work of Borghesi. These have been collected, down to the death of Augustus, by Henzen, and compared with the additional written testimonies, by Mommsen, in the *Corpus* (vol. i. p. 293 *sq.*; see also *Ephem. epigr.*, i. p. 154, ii. p. 210, 285, iii. p. 11 *sq.*; compare Hirschfeld and Mommsen in *Hermes*, vol. iii., 1874, pp. 93, 267 *sq.*), along with the *acta triumphorum* and other minor fragments of *fasti* found in various Italian communities (*C. I. L.*, i. p. 453 *sq.*; *Ephem. epigr.*, i. p. 157, iii. p. 16), while the *fasti sacerdotum publicorum populi Romani*, together with the *tabula feriarum Latinarum*, are given in the volume devoted exclusively to the monuments of Rome (vol. vi., p. 441 *sq.*; compare *Hermes*, vol. v., 1870, p. 379, and *Ephem. epigr.*, ii. p. 93, iii. pp. 74, 205 *sq.*). Documents of the same kind, as, for example, the *album ordinis Thamugadensis* from Africa (*Ephem. epigr.*, iii. p. 77 *sq.*), and a considerable mass of military lists (*latercula*, of which those belonging to the garrison of the metropolis are brought together in *C. I. L.*, vi. p. 651 *sq.*), are given on many dedicatory and honorary monuments, chiefly from Lambæsis in Africa (*C. I. L.*, viii.). As those documents, though having only a partial claim to be ranked with the sacred ones, derive, like many other dedicatory monuments, their origin and form from that class, so also the protocols (*acta*), which, from Augustus downwards, seem to have been preserved in the case of all important *collegia magistratuum*, now survive only from one of the largest and most distinguished *collegia sacerdotum*, in the *acta collegii fratrum Arvalium*, to which Marini first drew the attention of epigraphists; they form one of the most important masses of epigraphic monuments preserved to us in the Latin language (see *C. I. L.*, vi. p. 459 *sq.*, *Ephem. epigr.*, ii. p. 211 *sq.*, and Henzen's *Acta fratrum Arvalium*, Berlin, 1874).

6. Another species of instruments is formed by private documents. They have been incidentally preserved (inserted, for instance, into sepulchral and honorary inscriptions), in the later period not unfrequently in monumental form, as the testaments, given partly or in full, mentioned above (viz., that of Dasumius and the Gaul, *C. I. L.*, vi. 10229, Wil. 314, 315, and some *capita testamentorum* or *codicilli*, as that of M. Meconius Leo found at Petelia—Mommsen, *I. N.*, 78, 79; Orel. 3677, 3678; Wil. 696), and the donations, such as those of T. Flavius Syntrophus (*C. I. L.*, vi. 10239; Wil. 313), of T. Flavius Artemidorus (Wil. 310), of Statia Irene and Julia Monime (*C. I. L.*, vi. 10231, 10247; Wil. 311, 318). Of a peculiar description is the *pactum fiduciæ*, found in Spain, engraved on a bronze tablet, and belonging, in all probability, to the 1st century (*C. I. L.*, ii. 5042), which seems to be a formulary. Other documents relating to private affairs exist in their original form written on *tabellæ ceratæ*. Those found together in a mining district of Dacia have been arranged and explained by Mommsen and Zangemeister (*C. I. L.*, iii. p. 291 *sq.*, with facsimiles); those found at Pompeii in 1875, containing receipts of the banker L. Cæcilius Jucundus, have been published by De Petra ("Le tavolette cerate di Pompei," *Atti dell' Academia de' Lincei*, vol. iii., 1876) and explained by Mommsen (*Hermes*, vol. xii., 1877, p. 88 *sq.*). These documents are written in cursive letters; and so mostly, too, are some other curious private monuments, belonging partly to the sacred inscriptions,—the *defixiones*, imprecations directed against persons suspected of theft or other offences, who, according to a very ancient superstition, were in this way believed to be delivered to punishment through the god to whom the *defixio* was directed. The numerous Greek and Latin (and even Oscan) examples of this usage have been brought together by Wachsmuth (*Rheinisches Museum*, vol. xviii., 1863, p. 559 *sq.*; Henz., *Bullettino dell' Instituto*, 1866, p. 252; compare *C. I. L.*, i. 818–820, *C. I. L.*, vii. 140). Only a few of them are incised on stone (as that to the *Dea Atæcina* from Spain, *C. I. L.*, ii. 462); for the most part they are written, in cursive letters, or in very debased capitals, on small bronze or lead tablets (so *C. I. L.*, i. 818, 819; Henz. 6114, 6115; Wil. 2747, 2748), to be laid in the tombs of the "defixi," or deposited in the sanctuaries of some divinity. Some new specimens of this class have been lately added from Pavia and Arezzo in Italy (Mommsen, *Hermes*, vol. iii., 1868, p. 302, and vol. iv., 1869, p. 282 *sq.*; Wil. 2749, 2753, 2754); one was lately found at Bath (Zangemeister, *Hermes*, vol. xv., 1880, p. 588 *sq.*).

7. Many of the private documents just alluded to have not a monumental character similar to that of the other inscriptions in the wider sense of the word, as they are written on materials not very durable, such as wood and lead,—in the majority of cases, in cursive characters; but, nevertheless, they cannot be classed as literature. As a last species, therefore, of *instrumenta*, there remain some documents, public and private, which similarly lack the strict monumental character, but still are to be reckoned among inscriptions. These are the inscriptions painted or scratched on the walls of the buildings of ancient towns, like Pompeii, where, as was to be expected, most of them have been preserved, those from other ancient cities buried by the eruptions of Vesuvius and from Rome being very small in number. All the various classes of these inscrip-

tions—public and private advertisements, citations for the municipal elections, and private scribbings of the most diverse (and sometimes most indecent) character, once partly collected by Chr. Wordsworth (*Inscriptiones Pompeianæ*, etc., London, 1837, 1846)—are now arranged by Zangemeister in the *Corpus*, vol. iv. (see also *Ephem. epigr.*, i. pp. 49, 177 *sq.*, and some specimens in Wil. 1951 *sq.*), whence their peculiar palæographic and epigraphic rules may be learned. And, lastly, as related to some of these advertisements, though widely differing from them in age and character, may be mentioned the so-called *diptycha consularia*, monuments, in the first instance, of the still very respectable skill in this branch of sculpture to be found at this late period. They are, as is generally known, carved-ivory tablets, in the form of *pugillaria*, and seem to have been invitations to the solemnities connected with the accession of high magistrates, especially to the spectacles of the circus and amphitheatre; for they contain, along with representations of such spectacles, the names, and often the portraits, of high functionaries, mostly of the 5th and 6th centuries. Since Gori's well-known work on this class of monuments (*Thesaurus veterum diptychorum*, etc., 3 vols., Florence, 1759) no comprehensive collection of them has been published; as specimens see *C. I. L.*, ii. 2699, and v. 8120, 1–9.

Bibliography.—There is no "Textbook" of Roman epigraphy which can be recommended to the student. Brissonius, in his work *De formulis et solemnibus populi Romani verbis libri VIII.* (first published at Paris, 1583; edited, with additions by Conradi and Bach, at Frankford and Leipsic, 1754), gives some useful information about the *instrumenta;* Maffei, in his *Ars critica lapidaria* (published, after his death, in Donati's *Supplement* to Muratori, 1765), goes too far in his suspicions about forgeries; Morcelli's *Lexicon epigraphicum* (in his *Opera epigraphica*, 5 vols., Padua, 1819) is made for use in the composition of modern Latin inscriptions. Zaccaria's *Instituzione antiquario-lapidaria osia introduzione allo studio delle antiche latine iscrizioni* (Rome, 1770, and Venice, 1793) has its merits, though it is somewhat antiquated, and is, besides, a rather scarce book. But students must be warned against Zell's *Handbuch der römischen Epigraphik* (2 vols., Heidelberg, 1850–1852), which is a work in every respect thoroughly unsatisfactory. For Christian inscriptions Le Blant's *Manuel d'épigraphie chrétienne d'après les marbres de la Gaule* (Paris, 1869), on which the article in Martigny's *Dictionnaire des antiquités chrétiennes* (2d ed., Paris, 1877, p. 357 *sq.*) is based, and that in Smith and Cheetham's *Dictionary of Christian Antiquities* (vol. i., London, 1875, p. 841 *sq.*), may be consulted with advantage. (E. HÜ.)

INSECTIVOROUS PLANTS. Insectivorous or, as they are sometimes more correctly termed, carnivorous plants are, like the parasites, the climbers, or the succulents, a physiological assemblage belonging to a number of distinct natural orders. They agree in the extraordinary habit of adding to the supplies of nitrogenous material afforded them in common with other plants by the soil and atmosphere, by the capture and consumption of insects and other small animals. The curious and varied mechanical arrangements by which these supplies of animal food are obtained, the ways and degrees in which they are utilized, and the remarkable chemical, histological, and electrical phenomena which accompany these processes of prehension and utilization, can only be understood by a separate and somewhat detailed examination of the leading orders and genera. It is convenient to follow the order adopted by Mr. Darwin in his work on *Insectivorous Plants* (Lond., 1875), to which our knowledge of the subject is mainly due, incorporating, however, as far as possible, the leading observations of other writers on the subject. We must preface this, however, by a brief summary of the facts of taxonomy and distribution.

Taxonomy.—The best known and most important order—the *Droseraceæ*—is placed among the calycifloral exogens, and has obvious affinities with the *Saxifragaceæ.* It includes six genera—*Byblis*, *Roridula*, *Drosera*, *Drosophyllum*, *Aldrovanda*, and *Dionæa*, of which the last three are monotypic, *i. e.*, include only one species. The curious pitcher-plant, *Cephalotus follicularis*, is usually raised to the dignity of a separate natural order *Cephaloteæ*, though Bentham and Hooker (*Gen. Plant.*) place it among the *Ribesiaceæ.* The *Sarraceniaceæ* are thalamiflorals, and contain the genera *Sarracenia*, *Darlingtonia*, *Heliamphora*, while the true pitcher-plants or *Nepenthaceæ*, consisting of the single large genus *Nepenthes*, are placed near the *Aristolochiaceæ* among the *Apetalæ.* Finally the genera *Pinguicula*, *Utricularia*, *Genlisea*, and *Polypompholix* belong to the gamopetalous order *Utriculariæ.* Thus all the four leading divisions of the exogenous plants are represented by apparently unrelated orders; certain affinities, however, are alleged between *Droseraceæ*, *Sarraceniaceæ*, and *Nepenthaceæ.*

Distribution.—While the large genus *Drosera* has an all but world-wide distribution, its congeners are restricted to well-defined and usually comparatively small areas. Thus *Drosophyllum* occurs only in Portugal and Morocco, *Byblis* in tropical Australia, and, although *Aldrovanda* is found in Queensland, in Bengal, and in Europe, a wide distribution explained by its aquatic habit, *Dionæa* is restricted to a few localities in North and South Carolina, mainly around Wilmington. *Cephalotus* occurs only near Albany in Western Australia, *Heliamphora* on the Roraima Mountains in Venezuela, *Darlingtonia* on the Sierra Nevada of California, and these three genera too are as yet monotypic; of *Sarracenia*, however, there are six or eight known species scattered over the eastern States of North America. The 36 species of *Nepenthes* are mostly natives of the hotter parts of the Indian Archipelago, but a few range into Ceylon, Bengal, Cochin China, and some even occur in tropical Australia on the one hand, and in the Seychelles and Madagascar on the other. *Pinguicula* is abundant in the north temperate zone, and ranges down the Andes as far as Patagonia; the 150 species of *Utricularia* are mostly aquatic, and some are found in all save polar regions; their unimportant congeners, *Genlisea* and *Polypompholix*, occur in tropical America and south-western Australia respectively. It is remarkable that all the insectivorous plants agree in inhabiting damp heaths, bogs, marshes, and similar situations where water is abundant,—a peculiarity perhaps due to their habit of copious secretion and consequent need of water.

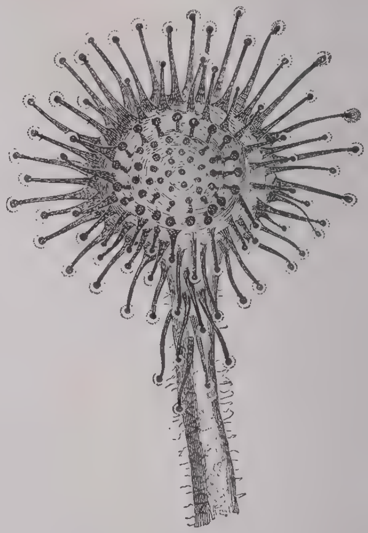

FIG. 1.—Leaf of Sundew (*Drosera rotundifolia*). ×4. After Darwin.)

Drosera.—The Common Sundew (*D. rotundifolia*) has extremely small roots, and bears five or six radical leaves horizontally extended in a rosette around the flowerstalk. The upper surface of each leaf is covered with gland-bearing filaments or "tentacles," of which there are on an average about two hundred. Each gland is surrounded by a large dew-like drop of a viscid but transparent and glittering secretion, and the popular names (Sundew, French *Rossolis*, German *Sonnenthau*) as well as the Linnæan (from δρόσος, dew) have been thus suggested. The stalk of the tentacle has the essential structure of a leaf. A small fibro-vascular bundle, consisting mainly of spiral vessels, runs up through the stalk and is surrounded by a layer of elongated parenchyma cells lined by a thin layer of colorless circulating protoplasm, and filled with a homogeneous fluid, tinted purple by a modification of chlorophyll (erythrophyll, Sorby). The epidermis bears small multicellular prominences. The glandular head of the tentacle contains a central mass of spirally thickened cells in immediate contact with the upper end of the fibro-vascular bundle. Around these (but separated from them by a layer of much elongated cells, Warming) there is a layer of cells filled with purple fluid, and outside these lies a similar series of cells, whose contents differ slightly in tinge, and in behavior when treated with reagents.

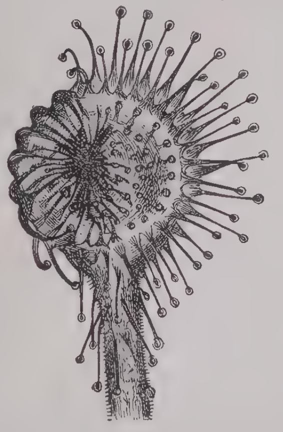

FIG. 2.—Leaf of Sundew, enlarged, with the tentacles on one side inflected over a bit of meat placed on the disk. (After Darwin.)

Insects seem to be attracted by the leaves of *Drosera*, but whether by their color, their glittering secretion, their odor, or by all three, remains as yet unsettled. A fly alighting on the disk, or even only touching one or two of the exterior tentacles, is immediately entangled by the viscid secretion; the tentacles to which it is adhering begin to bend, and thus pass on their prey to the tentacles next succeeding them inwards, and the insect is thus carried by a curious rolling movement to the centre of the leaf. The tentacles on all sides become similarly inflected; the blade or the leaf may even become almost cup-shaped; and the insect, bathed in the abundant secretion which soon closes up its tracheæ, is drowned in about a quarter of an hour. The leaves clasp also, but for a much shorter time, over inorganic bodies.

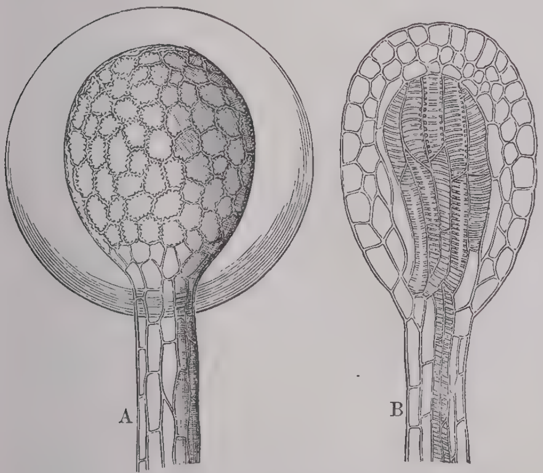

FIG. 3.—Glands of Sundew magnified. (After Dodel-Port). A, external aspect with drop of secretion; B, internal structure.

The bending of the tentacle takes place near its base, and may be excited (1) by repeated touches, although not by gusts of wind or drops of rain, thus saving the plant from much useless movement; (2) by contact with any solid, even though insoluble and of far greater minuteness than could be appreciated by our sense of touch,—a morsel of human hair weighing only $\frac{1}{78740}$ of a grain, and this largely supported too by the viscid secretion, sufficing to induce movement; (3) by the absorption of a trace of certain fluids, mostly nitrogenous. During the inflection of the tentacle, and even before it touches the stimulating object, the secretion of the gland increases in quantity, and, instead of remaining neutral, becomes acid.

The stalk of a tentacle whose gland has been stimulated by repeated shocks, continuous pressure, or the absorption of any nitrogenous fluid, particularly a solution of ammonic carbonate, shows a mottled appearance; and, when examined under the microscope the formerly homogeneous fluid contents of its constituent cells are seen to have separated into purple masses of constantly varying number, shape, and size, suspended in a colorless fluid, and the layer of colorless circulating protoplasm which lines the cells thus becomes much more distinctly visible. This process, which is termed by Darwin "aggregation of the protoplasm," commences in the glands and gradually travels down the tentacles, being temporarily arrested at each cell-wall. The process of redissolution of the protoplasm commences at the base of the tentacles and proceeds upwards. Aggregation is a vital process: the cells must be alive, uninjured, and oxygenated; if they are crushed or treated with carbonic acid the phenomenon does not take place. It is not necessarily related to inflection, for one may be induced without the other; it is totally unlike the "plasmolysis," or shrinking away of the protoplasm from the cell-wall, which takes place on treating a portion of vegetable tissue with any dense fluid, and which is simply due to exosmose; and it does not depend upon increased secretion. Darwin has also observed aggregation in the sensitive hairs of *Dionæa*, and in the roots of various plants; it seems indeed to be of wide distribution and profound importance in the physiology of the vegetable cell.

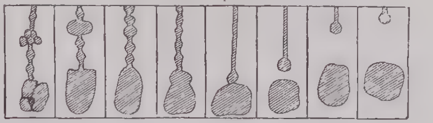

FIG. 4.—Diagram of the same cell of a tentacle of *D. rotundifolia*, showing the various forms successively assumed by the aggregated masses of protoplasm. (After Darwin.)

Effects of Heat.—Sachs asserts that plants are killed by immersion for ten minutes in water at 45° to 46° C., and that their protoplasm coagulates at 50° or 60°. Darwin, however, found that the immersion of leaves of *Drosera* for ten minutes in water at 50°, instead of killing the leaves, excited the tentacles into quick movement, that a temperature of 54°·4 paralyzed the leaves without killing them, and that some even survived a temperature of 62° C. Some of the lowest plants have frequently been described as living in hot springs, but that so highly organized a native of temperate and even almost arctic regions should withstand so high a temperature is very remarkable.

Action of Ammonia Salts.—All the salts of ammonia produce inflection, the carbonate strongly, the nitrate even more so, and the phosphate most of all. The immersion of a leaf in a solution of the last-mentioned salts, so weak that each gland could only absorb about $\frac{1}{20000000}$ of a grain, is sufficient to produce complete inflection of the tentacles. Though the particles of sold matter which stimulate the olfactory nerves, and so produce the sensation of odor in animals, must be infinitely smaller than this, as Mr. Darwin remarks, the fact remains truly wonderful that the absorption of so minute a quantity by a gland should induce some change in it, which leads to the transmission of a motor impulse down the entire length of the tentacle, causing the whole mass to bend, often through an angle of more than 180°, and this too in the absence of any specialized nervous system.

Action of various Salts and Acids.—In the case of salts the nature of the base seems to be of much more importance than that of the acid, a conclusion already arrived at by animal physiologists. Thus nine salts of sodium caused inflection, and were not poisonous; seven of the corresponding salts of potassium did not cause inflection, and some were poisonous. This is interesting in connection with the fact that large doses of sodium salts may be introduced into the circulation of mammals with impunity, whereas small doses of potassium salts speedily cause death. Of twenty-four acids tried, nineteen caused inflection, and the majority, even including most of the organic acids, were poisonous, which is the more remarkable since juice of many plants seems much more strongly acid than the solutions which were employed. The poisonous action, however, is not improbably connected with the negative osmose which is known to be induced by dilute acids.

Action of Alkaloid Poisons, of other Substances, and of Vapors.—Acetate and sulphate of quinine, citrate of strychnine, nicotine, digitaline, act more or less strongly on the glands and kill them; on the other hand, nitrate of quinine, atropine, veratrine, colchicine, theine, are quite harmless. Curare is not poisonous, and cobra poison, which kills animals by paralyzing their nerve centres, causes "strong and rapid inflection of the tentacles, and soon discharges all color from the glands," stimulating also the movements of their protoplasm. Since alkaloids which act strongly on the nervous system of animals are without effect on *Drosera*, it seems probable that the sensibility of its glands, and their power of transmitting a stimulus to other parts of the leaf, are not due to elements anologous to nerve. Camphor in solution acts as a stimulant; the vapors, however, of camphor, chloroform, alcohol, ether, and carbonic acid have a narcotic or anæsthetic action, and kill the plants after a time.

Effects of Organic Fluids.—Digestive Power of Secretion.—Darwin treated sixty-one leaves of *Drosera* with non-nitrogenous solutions (gum-arabic, sugar, starch, dilute alcohol, olive-oil, tea). The tentacles were not in a single case inflected. He then applied to sixty-four other leaves various nitrogenous fluids (milk, urine, albumen, infusion of meat, mucus, saliva, isinglass), and sixty-three had the tentacles and often the blades well inflected. Finally, taking twenty-three of the leaves which had served for the first experiment and treating them with bits of meat or drops of nitrogenous fluids, all save a few, apparently injured by exosmose caused by the density of the former solution of gum, sugar, etc., were distinctly inflected.

We are thus led to inquire whether the leaves have only the power of absorbing matter already in solution or whether they can render nitrogenous matter soluble, that is, whether they have the power of true digestion. The digestion of albuminous bodies by animals is effected by means of a ferment, pepsin, acting in presence of weak hydrochloric acid,—neither the acid nor the ferment having the power of digesting in the absence of the other, though almost any other acid may be substituted for hydrochloric. When the stomach is mechanically excited, acid is secreted, but not pepsin; this requires for its production the absorption of a minute quantity of already soluble animal matter (peptogene of Schiff). These propositions all hold good of *Drosera.* Frankland analyzed the secretion obtained by stimulating four hundred and forty-five leaves with particles of glass, and came to the conclusion that its acidity was due to some acid of the acetic series, apparently either propionic or a mixture of acetic and butyric acids. Analysis of larger quantities enabled Will to show that the secretion contained formic as well as probably butyric and propionic acid, and Rees and Will prepared a glycerin extract which when acidulated rapidly digested fibrin. Lawson Tait also separated a substance possessing the property of a digestive ferment.

Darwin fed numerous plants with roast meat and minute cubes of boiled white of egg, and placed other cubes in wet moss as a check. Solution soon took place in the former cases; and, just as in animal digestion, the edges of the cubes of egg were first rounded off, and the striation of muscle was replaced by dark points, while the bits of egg left in moss putrefied. On neutralization of the acid by alkali, digestion stops; on reacidification, it goes on again. Neither the watery nor the glycerin extract of leaves stimulated by fragments of glass was able to digest, showing that the ferment is not secreted until the glands have absorbed a trace of animal matter. The leaves digested fibrin, connective tissue, cartilage, bone, enamel, and dentine, gelatin, chondrine, casein of milk, etc., but could not digest epidermic productions (nails, hairs, feathers), fibro-elastic tissue, mucin, pepsin, urea, chitin, chlorophyll, cellulose, gun-cotton, oil, fat, and starch, thus completing the analogy with the gastric digestion of animals. Pollen-grains had their protoplasmic contents dissolved, and seeds were usually killed.

Irritability and Movements.—Cutting and pricking the leaf does not induce movement; the petiole is quite insensible, nor do the pedicels of the glands bend when rubbed or stimulated by contact with food. Only the glands remain, and these at once respond to stimuli, yet their irritability seems to extend for a very slight distance below them, since when the glands are cut off their pedicels often become inflected. When a tentacle receives an impulse either from its own gland or from the central tentacles, it bends towards the middle of the leaf, the short tentacles on which do not bend at all; in all other cases all the tentacles, even those of the centre, bend towards the point whence the stimulus comes. Thus all the tentacles of a leaf may be made to converge into two symmetrical groups by placing a fragment of phosphate of ammonia in the middle of each half of the blade. Contrary to the opinion of Ziegler, vivisection shows that the motor impulse is not transmitted through the fibro-vascular bundles, but through the cellular tissue. An impulse thus travels more rapidly along than across the leaf, since, from the elongated shape and the position of the cells, fewer cell-walls have to be crossed in a given distance. Thus, when the central glands are excited, they send centrifugally some influence to the exterior glands, where aggregation of the protoplasm is set up, which may be watched descending their tentacles, and the whole process is not without analogy to a reflex action. The motor impulse seems to be allied to the aggregating process, and it has been attempted to explain the bending which takes place at the base of the tentacles by assuming either (1) a rapid passage of fluid out of the cells in that region, which would thus contract, at least if we suppose them to be previously in a state of high tension and to possess great elasticity, (2) a contraction of the protoplasm of these cells, (3) the contraction of the cell-walls as well as the protoplasm, or (4) a shrinkage of the fluid contents of the cells, owing to a change in their molecular state with the subsequent closing in of the walls.

Absorption.—Bennett has described what he terms absorptive glands beneath the epidermis, consisting of two nearly hemispherical cells, filled with brownish protoplasm and bearing papillæ, which sometimes rise above the surface of the leaf, or the filaments of the tentacles. He finds similar organs in *Dionæa* and *Nepenthes*, but in no plants other than carnivorous, except *Callitriche.* Clark fed *Drosera* with flies soaked in chloride of lithium, and after several days found that all parts of the plant when burned showed the characteristic spectrum of lithium; and Tait, by cultivating plants with roots cut off and leaves buried in pure sand watered with an ammoniacal solution, showed that the sundew can not only absorb nutriment from its leaves, but can actually live and thrive by their aid alone, if supplied with small quantities of nitrogenous material.

Dionœa Muscipula, L.—This plant, the well-known Venus's Fly-trap, was first described in 1768 by Ellis in a remarkable letter to Linnæus, in which he gave a substantially correct account of the structure and functions of its leaves, and even suggested the probability of their carnivorism. Linnæus declared it the most wonderful of plants (*miraculum naturœ*), yet only admitted that it showed an extreme case of sensitiveness, supposing that the insects were only accidentally captured and subsequently allowed to escape. Two American botanists, Curtis and Canby, successively advanced our knowledge of the mode of capture and digestion, which has also been investigated by Mrs. Treat, T. A. G. Balfour, and others, and most fully by Darwin.

The leaves are all radical, with broad foliaceous footstalks. Each leaf has two lobes, standing at rather less than a right angle to each other, their edges being produced into spike-like processes. The upper surface of each lobe is covered with minute circular sessile glands, each consisting of from 20 to 30 cells filled with purplish fluid. It bears also three fine-pointed, sensitive filaments arranged in a triangle. These contain no fibro-vascular bundles, but present an articulation near their bases, which enables them to bend parallel to the surface of the leaf when the lobes close. When the filaments are touched by an insect, the lobes close very sharply upon the hinge-like midrib, the spikes interlock, and the insect is imprisoned. If very minute, and so not worth digesting, it is able to escape between the interlocked spines; more usually, however, it is retained between the lobes, which gradually but firmly compress it, until its form is distinguishable from without. The leaf thus forms itself into a temporary stomach, and the glands, hitherto dry, commence, as soon as excited by the absorption of a trace of nitrogenous matter, to pour out an acid secretion containing a ferment, which rapidly dissolves the soft parts of the insect. This is produced in such abundance that, when Darwin made a small opening at the base of one lobe of a leaf which had closed over a large crushed fly, the secretion continued to run down the footstalk during the whole time—nine days—during which the plant was kept under observation. Aggregation may be observed in the glands, and, at least on treatment with carbonate of ammonia, the aggregative process may be watched ascending the sensitive hairs.

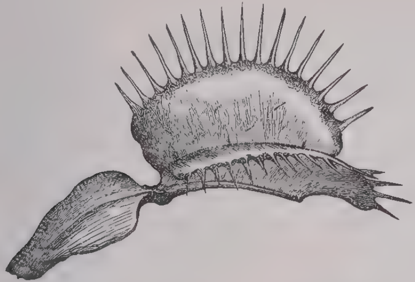

Fig. 5.—Leaf of Venus's Fly-trap (*Dionæa muscipula*), viewed laterally in its expanded state. (After Darwin.)

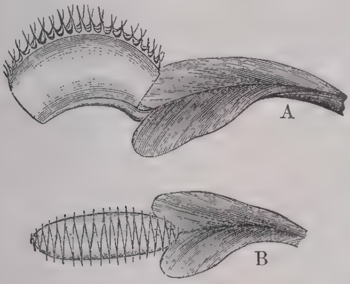

Fig. 6.—Leaf of *D. muscipula* closed over insect. A, viewed from the side; B, from above.

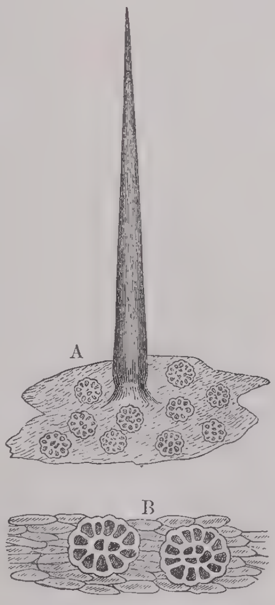

Fig. 7.—A, sensitive filament and glands of *D. muscipula*, × 50; B, glands, × 300.

Though the filaments are exquisitely sensitive to the slightest contact with solid bodies, yet they are far less sensitive than those of *Drosera* to prolonged pressure, a singular difference in evident relation to the habits of the two plants. Like the leaves of *Drosera*, however, those of *Dionæa* are completely indifferent to wind and rain. The surface of the blade is very slightly sensitive; it may be roughly handled or scratched without causing movement, but closes when its surface or midrib is deeply pricked or cut. Irritation of the triangular area on each lobe enclosed by the sensitive filaments causes closure. The footstalk is quite insensitive. Inorganic or non-nitrogenous bodies, placed on the leaves without touching the sensitive filaments, do not excite movement, but nitrogenous bodies, if in the least degree damp, cause after several hours the lobes to close slowly. So too the leaf which has closed over a digestible body applies a gradual pressure, which serves to bring the glands on both sides into contact with the body, and may also, as Balfour suggests, aid in absorption. Thus we see that there are two kinds of movement, adapted for different purposes, one rapid, excited mechanically, the other slow, excited chemically. Leaves made to close over insoluble bodies reopen in less than twenty-four hours, and are ready, even before being fully expanded, to shut again. But if they have closed over nitrogen-yielding bodies, they remain closely shut for many days, and after re-expanding are torpid, and never act again, or only after a considerable time. Even in a state of nature, the most vigorous leaves are very rarely able to digest more than twice, or at most thrice, during their life. The secretion is a true gastric juice containing formic acid, and like gastric juice has remarkable antiseptic powers. Lindsay fed leaves with such quantities of meat as to kill them with indigestion, yet showed that the meat inside the leaf remained perfectly fresh while portions hanging outside putrefied.

While evidence is thus afforded of the absorption of the products of digestion by the complete disappearance of fibrin, albumen, etc., placed upon the leaf of *Dionæa*, Fraustadt was able, by feeding leaves with albumen dyed with aniline-red, to color the contents and nuclei of the gland-cells.

The motor impulse, as in *Drosera*, is transmitted through the cellular tissue. Burdon Sanderson has demonstrated the existence of a normal electric current in the leaf of *Dionæa*, and the negative variation undergone by that current at the moment of closure of the leaf due to the conversion of electromotive force into mechanical work. This discovery, which is of the highest importance as showing the profound resemblance between the closure of the leaf of *Dionæa* and the contraction of a muscle, has been followed up and extended by Munk. C. de Candolle ascribes the closure of the valves to variations in the turgescence of the parenchyma of their upper surface.

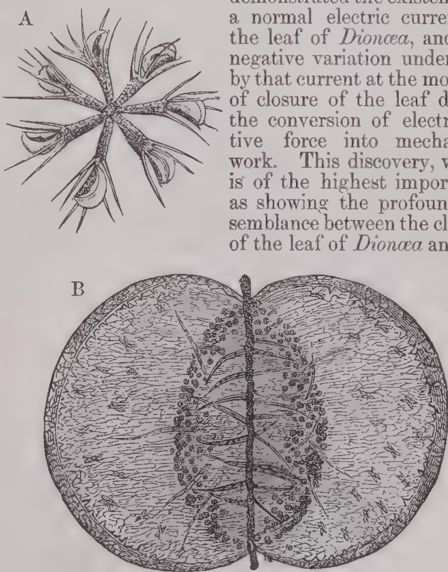

Fig. 8.—*Aldrovanda vesiculosa.*—A, whorl of leaves; B, leaf pressed open and enlarged, showing glands, sensitive filaments, and quadrifid hairs. (After Darwin.)

Aldrovanda vesiculosa.—This "minute aquatic *Dionæa*" floats freely, and is destitute of roots. Its whorled leaves have two lobes, with slightly inflected margins, which open only about as much as the valves of a living mussel-shell, and thus capture the more easily the small crustaceans and mollusks which may get between them. Part of the upper surface of each lobe next the midrib bears colorless glands (like those of *Dionœa*, but stalked), together with numerous long sensitive filaments which have both median and basal articulations; the outer thinner portion bears small quadrifid hairs. Darwin holds that the glands secrete and digest, while the quadrifids are destined to the absorption of decaying animal matter, the two regions of the leaf thus serving for very different purposes.

Drosophyllum lusitanicum.—This plant catches such vast numbers of flies in a state of nature that the Portuguese cottagers call it the fly-catcher, and hang up branches of it in their houses for this purpose. Its linear leaves are thickly covered with stalked glands which resemble in the main the tentacles of *Drosera*, save in that they are incapable of movement, and that their secretion is acid before excitement. The secretion too is less viscid, and freely leaves the gland to wet the insect, which, creeping onward, soon clogs its wings and dies. There are, moreover, many minute colorless sessile glands which only begin to secrete when stimulated by the absorption of nitrogenous matter, with which they seem to be mainly concerned.

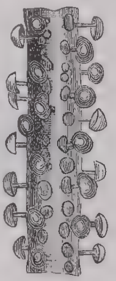

FIG. 9.—Part of leaf of *Drosophyllum lusitanicum.* × 7. Showing lower surface. (After Darwin.)

Roridula and *Byblis* resemble *Drosophyllum*, but their glands are of simpler structure than those of the latter, scarcely differing appreciably from the glandular hairs of other plants. Mr. Darwin has thrown considerable light upon the question of how far the glands of plants not adapted for capturing insects share the power of absorption exhibited by those of the *Droseraceæ.* Choosing a number of plants at hazard, he found that the glands of two species of *Saxifraga*, a genus distantly allied to *Drosera*, of a *Primula*, and of *Pelargonium* have the power of rapid absorption, and exhibit movements of aggregation in their protoplasm, whereas those of *Erica*, *Mirabilis*, and *Nicotiana* appear to have no such power. Heckel has made similar observations on the floral glands of *Parnassia palustris*, and on the leaf-glands of *Geranium sparmannia*, etc. The glandular hairs of at least some plants are known to be capable of absorbing ammonia, both in solution and in vapor, and probably some obtain animal matter from the insects which are occasionally entangled in the viscid secretion.

Pinguicula or Butterwort.—The large thick radical leaves of this genus have a very viscous surface and a pale color, and bear two sets of glands, the larger borne on usually unicellular pedicels, the smaller almost sessile. When a fly is captured, the viscous secretion becomes strongly acid, the naturally incurved margins of the leaf are excited to curve still farther inwards, and in short all the phenomena of secretion, aggregation, digestion, absorption, etc., may be observed which have been described in *Drosera.*

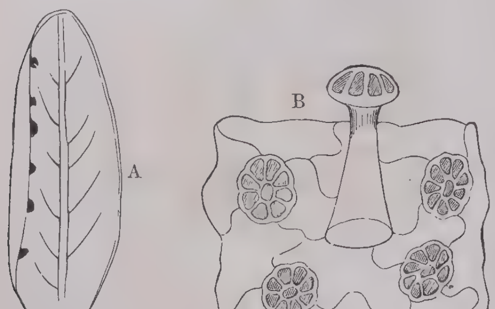

FIG. 10.—A, leaf of Butterwort (*Pinguicula vulgaris*), with left margin inflected over a row of small flies. (After Darwin.) B, glands from surface of leaf (× 300).

Utricularia.—The aquatic species of this plant are found floating in foul and stagnant water. Their much divided filamentous leaves bear bladders (fig. 11, A), averaging about $\frac{1}{10}$ of an inch in length, each of which bears six or seven long bristles around the mouth, which is fitted with a thin transparent valve, that opens inwards and is covered with peculiar glands. The interior of the bladder is lined by quadrifid hairs (fig. 11, B), like those described in *Aldrovanda.* Aquatic crustaceans, worms, insect larvæ, and other small animals easily enter by pushing inwards the posterior free edge of the valve, which is highly elastic. This instantly shuts against an interior thickened collar or projection around the mouth, and so renders escape impossible. The means by which the plant attracts its victims are unknown, but their success is very remarkable. Few bladders fail altogether, and many are found quite filled with crustaceans, as many as ten having been counted by Darwin within a single bladder. These bladders, however, have no secretion, and are quite unable to digest; they merely absorb the products of decomposition by means of their quadrifid hairs.

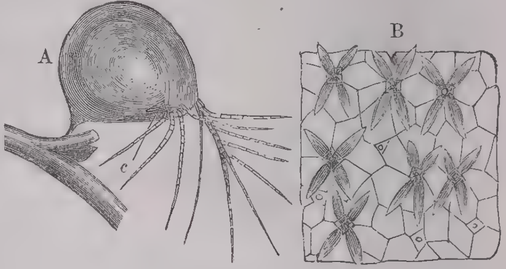

FIG. 11.—A, bladder of *Utricularia neglecta* (after Darwin), showing at *c* collar indistinctly seen through walls. B, quadrifid hairs from interior of bladder of *U. vulgaris* (× 300).

The terrestrial species (*e.g.*, *U. montana*), as also those of *Polypompholix*, bear numerous minute bladders of essentially similar structure along their creeping subterranean rhizomes, and these usually contain the decomposed remains of small terrestrial articulate animals. *Genlisea* has curious long-necked pitchers, lined with long downward-directed hairs, which at once aid an animal in its entrance and prevent its retreat.

Sarracenia.—Long supposed to be reservoirs of water for the birds, as was suggested by Linnæus, or refuges for insects from their pursuers, as was supposed by Catesby, the true function of the leaves of this curious plant has only been elucidated of recent years, mainly by the labors of Mellichamp and Hooker. The mouths of the long radical trumpet-shaped leaves are protected by a large spreading lid, the inner surface of which is abundantly smeared with nectar, and often gayly colored. Into one form of pitcher rain enters easily, into the other with difficulty. This with the mouth of the pitcher is furnished with numerous honey-secreting glands, and furnishes the attractive surface (fig. 12, A). A pathway too leads upwards from the ground along the broad wing of the pitcher, and is at least in some species also honey-baited; along this creeping insects are lured to their destruction. Below it is the conducting surface (B) of glassy epidermic cells, with short downward-directed points, which like those of *Genlisea* facilitate the descent, but impede the ascent of an insect. Then come the glandular surface (C), which is formed of smooth polished epidermis with numerous glands, that secrete the fluid contents of the pitcher, and finally the detentive surface (D), of which the cells are produced into long and strong bristles which point downwards and meet in the centre of the diminishing cavity so as to render escape impossible. The secretion wets an insect very rapidly, and appears to have remarkable anæsthetic effects. It seems to be completely destitute of digestive power, indeed rather to accelerate decomposition. The pitchers accumulate vast quantities of insects in the course of a season, and must thus abundantly manure the surrounding soil when they die. Moreover, the feast is largely shared by unbidden guests (commensals). Not to speak of insects which feed upon the pitcher itself, some drop their eggs into the putrescent mass, where their larvæ find abundant nourishment, while birds often slit open the pitchers with their beaks and devour the maggots in their turn.

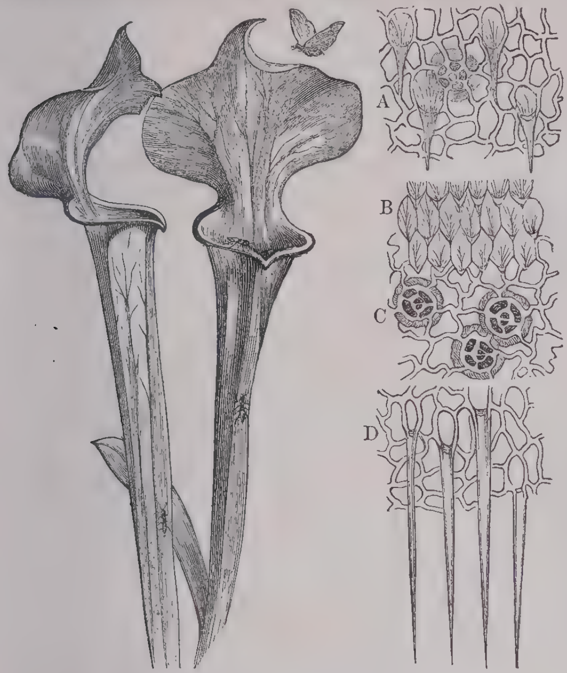

FIG. 12.—Leaves of *Sarracenia purpurea*. A, attractive surface of lid; B, conducting, C, glandular, and D, detentive surface; magnified. A and D are taken from *S. flava.*

Darlingtonia.—Of the two forms of pitcher in this genus the larger and ordinary form, that of the adult plant, is somewhat twisted, and instead of a lid has a large inflated hood overarching the small mouth. A large bilobed nectariferous and brightly colored expansion hangs down from this, and attracts insects, particularly moths. As in *Sarracenia*, the plant seems merely to absorb the products of their putrefaction.

Nepenthes.—The pitchers of this genus are borne at the ends of long tendril-like prolongations of the leaves, and are of considerable size, varying from an inch to a foot or more in depth. Again we have two varieties of pitchers, one belonging to the young state of the plant, short, broad, and provided with broad external wings, adapted for the capture of ground game, while the adult form, intended for winged game, is long, narrow, and often destitute of lateral appendages. The mouth of the pitcher is strengthened and kept open by a thickened rim, which, like the under surface of the lid, secretes honey, and is frequently produced inwards and downwards into a short funnel-shaped tube which prevents the escape of insects, or into a row of incurved hooks sometimes strong enough to retain a small bird. The younger form of pitcher has its whole interior lined by secreting glands; the other and more common form has an attractive, a conductive, and a secreting surface analogous to those of *Sarracenia*, but wholly different in histological details. The detentive surface is represented by the fluid secretion which is invariably present. This is developed before the pitcher opens, and has generally a faintly acid reaction; it contains, as shown by Voelcker, malic and citric acids, together with chloride of potassium, and carbonates of soda, magnesia, and lime. Hooker proved the digestive powers of the fluid, even on substances so resisting as cartilage; Rees and Will found that fibrin was dissolved even more rapidly by the secretion of the excited pitchers than in a test experiment with pepsin from the pig's stomach; and Lawson Tait, Vines, and others have obtained the ferment in a separate state. Tait indeed finds two substances, both possessing great antiseptic powers, and both being apparently, together with acid, essential to digestion—one a grayish-white precipitate with alkalies, which he terms "droserin," and which seems the analogue of pepsin; the other, "azerin," a transparent straw-colored substance precipitated by alcohol, he compares to ptyalin, the ferment of saliva. Droserin seems to be present in the secretion of all those insectivorous plants which possess the power of digestion, azerin perhaps in all without exception. The latter substance has the property of rapid deliquescence, so that it can only be preserved in hermetically sealed tubes, and its solution, like glycerin, quickly wets any body with which it comes in contact. A fly thrown into water never gets completely wetted, while one which falls into the secretion of any insectivorous plant is rapidly soaked and drowned by the fluid entering its tracheæ.

Cephalotus.—This plant bears ordinary leaves as well as pitchers. The latter somewhat resemble in general form those of *Nepenthes*, but are more complicated in histological details. Tait has proved the digestive action of their secretion.

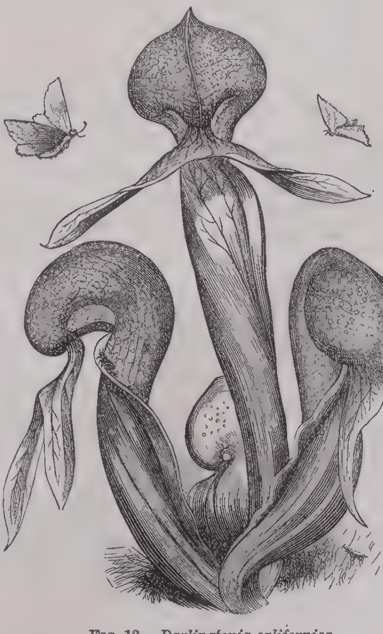

FIG. 13.—*Darlingtonia californica.*

Morphology of Pitchers.—Baillon, and indeed first of all Linnæus, have pointed out how by exaggerating the concavity of a peltate leaf like that of *Nymphæa* we obtain a pitcher of the type of *Sarracenia*. Intermediate forms are frequently shown by a variety of *Piperomia arifolia*. Hooker has given reason to believe that the pitcher of *Nepenthes* is not a transformed leaf, but a mere leaf-appendage answering to the water-secreting gland found at the end of many leaves. The apex of the leaf, instead of forming the lid as in *Sarracenia*, is represented by a filiform appendage (see fig. 16, F). Finally, Dickson has proved by comparison with monstrous forms that the pitcher of *Cephalotus* arises in a third and totally distinct way, by calceolate pouching from the upper surface of the ordinary spathulate leaves, the lid here arising from the proximal side of the pitcher-orifice.

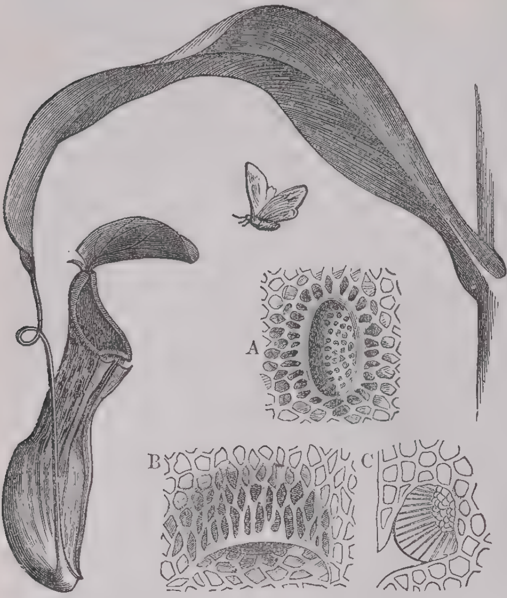

Fig. 14.—Pitcher of *Nepenthes distillatoria.* A, honey-gland from attractive surface of lid; B, digestive gland from interior of pitcher, in pocket-like depression of epidermis, opening downwards; C, transverse section of the same. A, B, and C magnified about 100 diameters.

Other Insectivorous Plants.—*Dischidia*, an Asiatic genus of *Asclepiadaceæ*, and *Martynia*, one of the *Pedalineæ*, have also been described as insectivorous, as well as *Caltha dionæfolia* and several Aroids. Even *Anomoclada*, a South American liverwort, and a fern (*Elaphoglossum glutinosum*) have been described by Spruce as capturing numerous insects. All these cases, however, require much further investigation. The connate leaves of *Dipsacus* frequently enclose water in which insects are drowned, and Francis Darwin has discovered protoplasmic filaments which are emitted by the cells of certain glands within these cups, and which appear to absorb the products of decomposition. A similar process has recently also been shown by Ludwig to occur in *Silphium*, an allied genus.

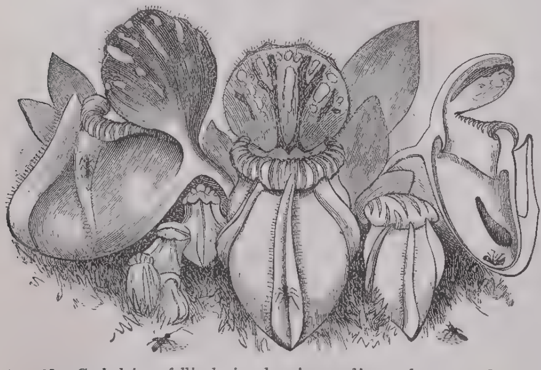

Fig. 15.—*Cephalotus follicularis*, showing ordinary leaves and pitchers, the right hand one cut open to show internal structure.

Conclusion.—When Mr. Darwin's work appeared, numerous objections were made to accepting his conclusions, on the *a priori* ground that digestion was too purely an animal function to be conceivable of plants. Morren demolished these by showing that digestion—the conversion of insoluble and indiffusible proteids, fats, and amyloids into soluble and diffusible compounds by means of appropriate ferments—is not confined either to animals or to carnivorous plants, but is a universal property of living beings, in fact the necessary preliminary of all assimilation. Not only are all the important animal digestive ferments represented among plants, but vegetable physiologists have made us acquainted with several ferments—synaptase, erythrozyme, myrosine, etc.—which have no known analogues in the animal kingdom. It is merely the exudation, not the existence, of the ferment, then, which is remarkable in carnivorous plants, and this Darwin suggests might begin by an exosmose accompanying the absorption of animal matter by any plant possessing viscid glandular hairs, and, once set up, would be perfected by natural selection. Insectivorous plants too are not the only ones which exhibit peculiarities of nutrition. The true parasites absorb the juices of the plants which they infest, and, not to mention the fungi, many of which subsist partly or wholly on animal matter, the phanerogamous saprophytes (*Neottia*, *Monotropa*, etc.) live by absorbing the partially decomposed materials of other plants; and from the absorption of vegetable to that of animal matter the transition is easy. The reciprocal case too occurs in the animal kingdom; animals possessing chlorophyll have been shown to nourish themselves like plants, without feeding, by decomposition of carbonic acid and the formation of starch in sunlight, and thus carnivorous plants—trespassers into the animal kingdom—are paralleled by vegetating animals. Thus, then, we have only to change our standpoint, and look, not at the anomalous plant or animal, but at the essentially similar cells, and the yet more essentially similar protoplasm of which both are composed, to see that their apparent anomalies are but additional proofs of the unity of nature.

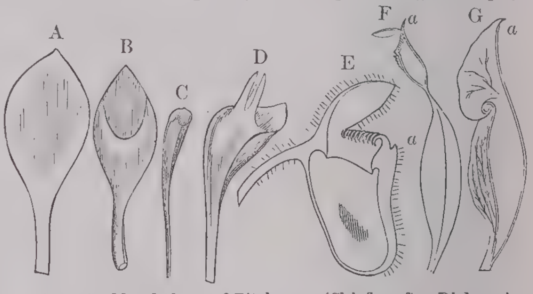

Fig. 16.—Morphology of Pitchers. (Chiefly after Dickson.) A, ordinary leaf of *Cephalotus*; B, monstrous leaf with spoon-shaped depression; C and D, other abnormal forms more deeply pouched, showing formation of pitcher; E, ordinary pitcher of *Cephalotus*; F, pitcher of *Nepenthes*; G, pitcher of *Sarracenia*; *a*, apex of leaf.

But a more serious criticism affected the completeness of Darwin's work. Though Knight in 1818 had thought plants of *Dionæa* on which he placed morsels of beef grew more luxuriantly than others not so treated, many observers have since failed to see any improvement on insectivorous plants when regularly fed, or any disadvantage when prevented from obtaining animal food altogether; while others have even asserted that animal food was hurtful, having injured or killed their plants by feeding. In the latter case the explanation was of course that the feeding was excessive, but to meet the objections of the former a very careful research was undertaken by Francis Darwin. He took six plates full of thriving plants of sundew, and divided off each by a transverse bar. Then, choosing the least flourishing side of each, he placed, on June 12, 1877, roast meat, in morsels of about $\frac{1}{50}$ of a grain on the leaves, and renewed the dose occasionally. The plants on the fed sides were soon clearly greener than those on the starved sides, and their leaves contained more chlorophyll and starch. In less than two months the number of flowerstalks was half as numerous again on the fed as on the unfed sides, while the number and diameter of the leaves and the color of the flowerstalks all showed a great superiority. The flowerstalks were all cut at the end of August, when their numbers were as 165 to 100, their total weight as 230 to 100, and the average weight per stem as 140 to 100 for the fed and unfed sides respectively. The total numbers of seed capsules were as 194 to 100, or nearly double, and the average number of seeds in each capsule as 12 to 10 respectively. The superiority of the fed plants over the unfed was even more clearly shown by comparing their seeds, the average weights per seed being as 157 to 100, their total calculated number as 240 to 100, and their total weight as 380 to 100. The fed plants, though at the commencement of the experiment in a slight minority, at the end of the season exceeded the unfed by more than 20 per cent., while the following spring the young plants which sprang up on the fed side exceeded those on the other by 18 per cent. in number and by 150 per cent. in total weight, so that, in spite of the relatively enormous quantity of flowerstalk produced by the fed plants during the previous summer, they had still been able to lay up a far greater store of reserve material.

It is to be remarked that the beneficial effect of feeding, although distinct in the vegetative system, is much more remarkable in the reproductive, a fact which explains the unfavorable opinion of previous observers.

These results were also independently arrived at by three German observers, Rees, Kellerman, and Von Räumer, who used aphides instead of roast meat. The question of the utility of the carnivorous habit may thus be considered as no less indisputable than its existence.

Bibliography.—Besides Darwin, *Insectivorous Plants*, 1875, and Hooker, *Brit. Assoc. Report*, 1874, p. 102, the reader may with advantage consult the following authorities. From them he can easily obtain complete references to the minor papers, which are too numerous for mention here. General Subject:—Planchon, "Les Plantes Carnivores," *Rev. d. Deux Mondes*, February, 1876; Dodel-Port, *Illustrirtes Pflanzenleben*, Zurich, 1880; Morren, *La Théorie des Plantes Carnivores et Irritables*, 2d ed., Liége, 1876; Cramer, *Ueb. d. (P. GE.)

INSECTS.

THE INSECTA, or INSECTS, form the largest class of that division of the animal kingdom formerly called *Articulata*, but for which the more expressive term *Arthropoda* (joint-footed) is now more generally employed. This term includes, besides *Insecta*, the classes *Crustacea*, *Arachnida*, and *Myriopoda*.

The chief diagnostic characters of an Insect, as combinedly distinguishing it from a Crustacean, an Arachnid, or a Myriopod, are as follows:—Legs usually (never more than) six in number; two antennæ; ordinarily two pairs of more or less membranous wings; head, thorax, and abdomen distinctly separated; respiration effected by means of internal tracheæ, which communicate with the air by lateral openings termed spiracles or stigmata, or by external plates or filaments (these ordinarily only in the preparatory conditions of aquatic forms), which absorb air and convey it to the tracheæ. A reference to the articles on the other classes of *Arthropoda* will indicate in what way these diagnostic points are modified in them.

As in all organized beings, the limits of the class are not strongly defined, for, although it is not difficult to indicate an insect, speaking broadly, there are certain small groups that do not satisfactorily fall into the class as limited by strongly marked lines of demarcation. These will be especially alluded to hereafter.

Number of Species of Insects.—At the head of this article it is stated that the *Insecta* form the largest group of the *Arthropoda*; it might probably be said with justice that they far outnumber all the other members of the animal kingdom combined. It is certain that at the present time 80,000 presumably distinct species of beetles have been described, and it is safe to assume that the number of known species of other orders is greater, thus giving a total of about 200,000. And yet we are only on the threshold of a knowledge of the forms that actually exist in nature. many enormous groups of minute forms being still only very partially studied. In fact, it may be confidently anticipated that some day the number of known forms will not fall far short of 1,000,000.

Antiquity of Insects.—Fossil indications have been discovered in the Devonian series, and in the Carboniferous they become rather more numerous; but, with few exceptions, these all belong to those orders in which the metamorphoses are incomplete, and there is no evidence that any anthophilous insects (such as *Lepidoptera* or *Hymenoptera*) were then in existence. Ascending the geological scale to the Mesozoic age, the representatives of the older groups become very numerous, and often of gigantic size. *Coleoptera* are fairly well indicated; and the flower-loving *Lepidoptera* and *Hymenoptera* make their appearance, but in very small numbers. In the Tertiary rocks remains become sometimes very abundant, and of all orders; and in the post-Tertiary or Quaternary period these remains consist largely of those of species now existing. One of the most interesting features in fossil entomology is the well-known occurrence of myriads of insects entombed in the fossil resin known as amber, preserved in the most beautiful manner, and belonging for the most part to genera now existing, but differing specifically. In alluding to this it is well to mention that the insects found in gum copal and other recent resins are, on the contrary, of existing species. As in other animals, and also plants, the fossil remains prove that the distribution of heat and cold on the earth was once very different from what it now is: a fossil beetle of rather large size was discovered by our last Arctic Expedition almost at the highest northern point attained.

Geographical Distribution.—It may be asserted that no part of the earth's surface is without insects. They have been discovered in the Arctic and Antarctic regions at the highest point reached, and even showy butterflies of several species enliven the dreary solitudes of almost everlasting ice, as was abundantly proved by the naturalists of the "Alert" and "Discovery," who found them almost up to 83° N. lat. But, as a rule, the larger and more brilliant forms occur within the tropics. Yet it must not be assumed, as is sometimes erroneously done, that the majority of tropical insects are large and brilliant, and the smaller and more obscure forms comparatively less numerous. Recent investigations by competent observers show that the latter are at least as abundant in the tropics as in temperate regions, and that it is the wealth of large forms that has caused the others to be overlooked.

The attempts at subdivision of the globe into zoological regions, so successful with regard to mammals, and in a smaller degree with birds, have not been so entirely satisfactory with regard to insects, more especially as concerns the separation of the Palæarctic and Nearctic regions (see DISTRIBUTION); still there is often a very marked localization in particular groups, which divide themselves specifically to an infinite extent within very circumscribed areas, and are found nowhere else. The results obtained from minute investigation of insular faunæ have derived much of their value from insects, and have occasioned much valuable philosophical speculation on the origin both of the islands themselves and of their faunæ and floræ. Space will not permit of detailed allusion to the apparent affinity shown by the insect inhabitants of regions now very widely separated, such, for instance, as that of Western Europe with Western (rather than Eastern) North America, of Australia and New Zealand with Chili, of Chili and the southern extremity of South America with the Palæarctic region, etc.

As special points of distribution may be mentioned the occurrence of insects in hot springs, in brine, in the deepest caves (these are usually blind), below low-water mark, and even on the surface of the ocean (the genus *Halobates* in the *Hemiptera*) very far from land.

The power of many insects to acclimatize themselves rapidly when accidentally introduced into new regions is very marked, and adds to the difficulty often experienced in considering what species are really endemic and what introduced, especially in islands. Some of the common and noxious British species thrive enormously when introduced into Australia and New Zealand; and there is every reason to believe that the grape-vine pest (*Phylloxera*) was originally an importation from America.

Duration of Life.—The maximum duration of the life of a perfect insect is probably attained in bees and ants, the females or queens of which are known to live at least seven years; the minimum is found in some species of May-flies (*Ephemeridæ*), in which twenty-four hours is perhaps the limit. But the length of life of a perfect insect is sometimes in direct opposition to that of the same insect in its preparatory stages, and some of the *Ephemeridæ* that live at most but a few days in their aerial form have taken three years to complete their growth in their sub-aquatic stages. Temperature also has a marked effect on some species. The common house-fly, for instance, will complete its whole life-cycle from embryo to fly in a few days in the heat of summer, but requires very much longer in cold weather.

Economic Entomology.—Within the limits of an encyclopædia article it is impossible to give even a sketch of this subject. Those who desire an exhaustive résumé cannot do better than consult Kirby and Spence's delightful *Introduction*, even although it may be now somewhat out of date. Some especially noxious species—such, for instance, as the grape-vine pest, the Colorado beetle, and the Rocky Mountain locust—had not then been alluded to as occasioning damage, or were even altogether unknown. As concerns American species, Riley's *Reports on the Noxious, etc., Insects of Missouri* are mines of information. Amongst insects that are of direct benefit to man the hive-bee and the silk-worm moth stand pre-eminent, and the cochineal and lac insects are scarcely of less importance. No substitutes for silk, honey, and beeswax have been or are likely to be discovered; but, on the other hand, chemical discoveries have now occasioned the disuse of some insect products that were formerly valuable articles of commerce, and in this category nothing is more remarkable than the manner in which the oak-gall of commerce has given way to inorganic substances in the manufacture of ink. As food for man, insects play a very unimportant part, and they can scarcely be said now to form part of the diet of the more highly civilized races, notwithstanding an attempt lately made in America so to utilize the masses of the destructive Rocky Mountain locust. Yet locusts themselves (with other large insects) are eaten raw or cooked by the inhabitants of more than one part of the globe, and the large fleshy grubs or larvæ of beetles and other insects are as much esteemed as delicacies by the natives of some countries as the *Cossus* (the precise identity of which appears involved in some uncertainty) was by the luxurious Romans. The aborigines of Australia make a cake of the pounded bodies of a night-flying moth (*Noctua spini*), termed the Bugong moth; the natives of the Lake region of Central Africa make a kind of bread of the multitudes of small dead insects (chiefly *Ephemeridæ* and *Diptera*) that collect on the shores; in Central America the eggs of a large water bug supply materials for a kind of bread.

Noxious insects are legion, and cannot here be alluded to even in the most general manner. The number of those that cause injury to man by direct attacks is comparatively small; it is by their attacks on the produce of our fields and gardens that insects assert their importance. But it should not be overlooked that the especial province of insects is to act as scavengers, and very frequently they are not the initiating cause of damage, which is rather to be sought in a previously unhealthy condition of the trees or plants; they simply step in to complete the work of destruction commenced by disease or by a low state of the vital functions.

Insects and the Fertilization of Plants.—Such is the importance of insects in the economy of nature, and as conferring indirect benefit on man, in this particular, that this subject might have been alluded to under the preceding heading. That the action of insects in fertilizing plants was often necessary had long been known. But it is owing to the patient and laborious researches of living naturalists (amongst whom the names of Darwin, Hermann Müller, and Lubbock stand prominently forward) that the vast importance of the subject has come to be understood. They have proved incontestably that in a multitude of plants the condition of the reproductive organs is such that self-fertilization is impossible; but what is of greater importance is the proof afforded that, although many plants are perfectly capable of self-fertilization, the weight and number of the seeds or fruit are often vastly increased when cross-fertilization is effected, and that this is mainly done by the action of insects, the wind and other causes playing only a minor rôle. It may be truly said that such is the correlation between plants and insects that the majority of the former would more or less gradually disappear from the earth's surface were the latter to be destroyed. In New Zealand the red clover has been introduced and flourishes, but all hopes of spreading it there have to be abandoned; the plant never perfects its seeds, owing to the absence of humble bees, which appear absolutely necessary for its fertilization.

Parasitism.—Among the varied relations of insects to other classes of the animal kingdom and their mutual relations, no subject is more interesting than is that of parasitism. It occurs in almost all the orders, but in very different degrees. Whole groups are naturally epizoic, others entozoic, while a few (such as fleas and bed bugs) can scarcely be arranged in either of these divisions, inasmuch as, although in one sense epizoic, it appears probable that they may occasionally be able to go through the whole of their life-cycle without contact with the animals to which they otherwise appear especially attached. As true epizoa the whole group of true lice, *Anoplura* (which are probably degraded *Hemiptera*), and bird lice (*Mallophaga*, a group of uncertain affinities) are especially familiar. These cannot exist without their hosts, and their whole life is passed on them, each mammal or bird having its especial parasite (or more than one), which affects it only, or is at any rate confined to it and allied species. Such also are certain degraded forms of *Diptera*, including the bat parasites (*Nycteribia*), the bird flies (*Ornithomyia*), and others. Such also is a curious creature (*Platypsylla*) parasitic upon the beaver, the affinities of which are so little marked that it has been formed into a distinct order (*Achreioptera*) by Westwood, placed in the *Hemiptera* by Ritsema, and declared to be a true beetle by Leconte. Such also is a curious little moth (*Epipyrops*, Westwood), an external parasite upon certain homopterous insects; another moth (*Tinea vastella*) lives in its larval state on the horns of living animals; and many others might be cited.

As entozoic insects, the large dipterous family *Œstridæ* is especially characteristic, all its members living at the expense of *Mammalia* in very varied manners, the stomach, throat, frontal air passages, the subcutaneous system, and even the genital organs being attacked by various species, but only as larvæ, the perfect insects being winged and strong flyers. Furthermore, a genus of *Diptera* (*Batrachomyia*) belonging to quite another family (*Mucidæ*) is said to attack frogs. It is scarcely just, however, to class as true parasites certain insects whose larvæ have been discharged still (living) from the nostrils, intestines, or urethra of man. Many such cases have been perfectly authenticated, but the insects have been such as certainly do not of necessity require such conditions, and these latter are not natural habitats. Accident introduced them, and they were fitted to exist, at any rate for short periods, in the interior of the human body. But the largest class of insect parasitism is that which exists between insects themselves, as exhibited in an enormous number of certain families (*Ichneumonidæ*, *Evaniidæ*, *Proctotrypidæ*, *Chalcididæ*, etc.) of *Hymenoptera*, etc. These are essentially parasitic in their preparatory stages, and the parasitism is of the class that may be termed entozoic. The eggs are laid either in or on the bodies of the larvæ (chiefly) of other insects, and even in the eggs, the young larvæ of the parasites feeding mostly on the adipose tissue of their hosts, often enabling the latter to undergo most of their transformations (but very rarely that to the perfect insect). To such a class belong also many dipterous insects, chiefly belonging to the *Tachinidæ*. Hyper-parasitism exists in many minute species of *Chalcididæ*, which do not directly affect the hosts themselves, but which feed in the bodies of other parasites.

Luminosity.—This is another subject that should have more than passing notice bestowed upon it. Modern scientific travellers have not succeeded in confirming Madame Merian's well-known statements with regard to the luminosity of the so-called lantern-flies (*Fulgora*), hence these have to be eliminated from the category of luminous insects. It is among the *Coleoptera* that the phenomenon especially occurs, and in them is almost confined to certain skip-jack beetles (the genus *Pyrophorus*), and probably the entire family of glow-worms (*Lampyridæ*). The luminosity is confined to certain distinct patches, differing in position and number according to the species and also according to sex,—usually most observable in the female, although this does not appear to be always the case. The property is distinctly under the control of the insect, and is often exercised in an intermittent manner at stated intervals, when the insects are not under the influence of extraordinary excitement. It is probable that luminosity exists in some *Diptera*, and also in the larvæ of certain exotic *Lepidoptera*, a recent traveller having assured us that in South America a larva of this order has luminous patches along either side, so that when in motion it has been compared to a lighted-up railway train. Some occasional instances of luminosity appear to be accidental, probably owing to the insects having been feeding upon, or otherwise in contact with, decaying phosphorescent matter. With regard to the nature of the luminous substance no very precise results have been arrived at by investigators. That it is phosphorus in some form or other appears certain, and the latest experimenter (Jousset de Bellesme) asserts as his belief that it is no other than phosphoretted hydrogen gas stored up in the cellular tissue, and in direct communication with the nervous and respiratory systems.

Galls.—These well-known insect-productions are alluded to chiefly in order to call attention to the mystery that surrounds their growth. Galls are occasioned by the presence of the larvæ of certain species in nearly all orders of true insects, though it is amongst the *Cynipidæ* in *Hymenoptera* and the *Cecidomyiidæ* in *Diptera* that they are most characteristic. And they may be in almost any position on a plant, according to the species of gall-maker. The most striking, however, are clearly modified leaf or flower-buds.

The mystery surrounding galls is their cause. The indirect cause is the puncture of the insect, and the presence of its eggs or larvæ, but no explanation has been offered of the reason why this presence sets up the growth termed a gall. Two insects of differing species will deposit their eggs in the same position: in the one case no abnormal growth follows; in the other some peculiar irritation sets up a tumor, often enormous in size. Two insects, also of different species, but both gall-makers, do the same: in both cases a tumor ensues, but its form is totally different in the two. A most noticeable recent discovery is that by Dr. Adler (since confirmed by others) to the effect that in certain European *Cynipidæ* dimorphism to a remarkable extent occurs, and that certain genera are only conditions of others, the two forms of insects, and the totally different galls occasioned by them, being alternate in appearance.

External Structure.—Taking any large insect, we recognize in it three more or less distinctly separated divisions, the head, thorax, and abdomen. Taking the majority of insects, and especially of their larvæ, we recognize thirteen segments or somites, counting the head as one, the thorax as consisting of three, and the abdomen as nine. From a classificatory point of view, it is probably convenient to retain this idea, though in the abdomen of a dragon-fly (for instance) there are 10 quite distinct segments. But, seen in the light of embryology and morphology, a different aspect is put on. The abdomen in the embryo of some insects clearly consists of 11 segments. Moreover if each appendage of the head be considered as a modified limb, we get in some insects as many as 7 segments in this portion of the body alone. Thus although 13 segments is a usual and convenient number as regards the structure of an insect, this number must be vastly increased if we consider the animal in regard to other divisions of the Arthropod series. In the abdomen the actual number is sometimes very much reduced, owing to several of the segments becoming obsolescent, coalescent, or retracted.

The exoskeleton, or outer covering, is more or less hornlike in its nature. But its elements are by no means similar to those of either horns or bones. It is composed to a varying extent of phosphate of lime, with the addition of a peculiar substance termed *chitine*, especially characteristic of, though not strictly confined to, the *Insecta*. According to recent analysis, the constituents of chitine are said to be as follows:—

Carbon	45·69	Nitrogen	7·00
Hydrogen	6·42	Oxygen	40·89

The head, or anterior of the three main divisions of the body, of a perfect insect is of very varying form and structure, both as regards outline, the condition of its attachment to the trunk, and the details of its special appendages. No account of these variations can be given here; they will be briefly alluded to in the classificatory portion of this article. The various organs and appendages may be stated as follows. On each side of the anterior portion are inserted two long and usually multi-articulate processes termed "antennæ," which are tubes containing nerve-prolongations and tracheæ, and undoubtedly associated in a high degree with the special senses; but, notwithstanding all the controversy on the subject that has existed and still exists, we do not yet know clearly what is their special function. They have been considered organs of touch, of hearing, of smell, or simply as balancers assisting and directing flight. No one who has watched the proceedings of many insects (and especially of ants), when meeting others of their kind, can doubt that they act in some way (but perhaps not in all insects) as means of intercommunication, and thus take a high rank as important structures. They are, as a rule, much less developed in those insects having very large eyes; and in the larvæ of those that undergo a complete metamorphosis they are usually rudimentary only, notwithstanding their often enormous development in the perfect insects produced from the same larvæ.

The compound eyes are two in number (though each is occasionally divided into two portions), usually of large, sometimes of enormous size, and each consisting of very numerous facets, which but indicate the faces of so many independent angular tubes separated by layers of pigment. In the larval state the eyes are ordinarily simple, and each eye is usually a congregation of separate eye-spots. Besides the compound eyes, there are two or three (or no) small simple eyes, "ocelli" or "stemmata," each with a simple nerve, and never present in the larvæ or (probably) pupæ.

The organs of the lower surface of the head are of a most complicated nature, and are excessively modified according as the insect takes nutriment by biting or by sucking. Below the eyes is the "front;" this is succeeded by a piece termed the "clypeus" (or "epistome" or "nasus"), which is followed by the "labrum" or upper lip. On either side are the "mandibles" (usually dentate within) articulated to the cheeks, and below these a second pair of jaws, compound in structure, and consisting of a hinged base, afterwards frequently dividing into two portions, the "maxillæ" and maxillary lobes, and provided externally with articulated appendages known as the maxillary palpi. Below the mouth is the "labium" with its labial palpi, articulated to the "mentum" or chin-piece; lying within this lower mouth-covering is the "lingua" or tongue. The same general arrangement is present throughout all insects, and also in the larval and pupal stages; but the differing conditions of the food cause extreme modification, not only between differing groups or orders of the perfect insects, but also in the metamorphic stages of the one and the same species. In some insects there are additional small structures, such as the "paraglossæ."

The "thorax" is the next main division. It is composed of three distinct portions, the prothorax, mesothorax, and metathorax, all subject to excessive modifications; but the last is, on an average, the smallest; at any rate it seldom exceeds the intermediate, and is usually very much smaller. According to surface, each portion receives two different names; thus the upper side consists of the pronotum, mesonotum, and metanotum, the lower of the prosternum, mesosternum, and metasternum. It will be noticed also that each subdivision is again subdivided by more or less distinct grooves, especially above and on the sides, indicating its compound nature, and each of these has its special term, so that some authors go so far as to say that each thoracic division is formed of nine separate pieces (a text book on entomology, which this article cannot be, should be consulted as to these). In those insects in which the wing-power is great, the attachments of the muscles are strongly indicated externally.

The appendages of the thorax are the legs and wings. The legs are articulated members, of which one pair is attached to the sides of each subdivision. All true insects have but six actual legs, but in the larvæ of some orders there are simple fleshy prolegs on the abdominal segments, considered as representing the homologues of those abdominal legs so conspicuous in the *Myriopoda*. Of the true legs the anterior (or prothoracic) pair are directed forward, the two other pairs backward. Each leg consists of a basal joint or coxa (frequently not movable) inserted in sockets termed the acetabula; this is followed by a small joint termed the trochanter placed between the coxa and femur or thigh, which is ordinarily the largest joint, and is enormously developed in saltatorial insects. To this succeeds the tibia, followed again by the tarsus, which is ordinarily compound, but may consist of any number of joints from one to five. The tarsus is terminated by a pair (seldom one only) of claws, between which are more or less membranous arolia or plantulæ (much marked in the feet of *Diptera*, which climb polished surfaces, etc., by means of them), and also a pulvillus or cushion.

Wings are appendages of the mesothorax and metathorax (never of the prothorax), and, viewed simply as organs of locomotion, may be considered as expansions of the integument, though some morphologists object to this simple definition, and one at least (F. Plateau) regards them as tracheal extensions. Although in all orders there are cases in which they are never developed, the exceptions being so few as abundantly to prove the rule, yet the posterior (or "hind" or "under") pair may be absent, and the anterior (or "fore" or "upper") ample. So strongly are they attributes of a perfect insect, that in some cases in which neither pair is developed the creatures strongly incline to retain their larval form. Normally the first external indications may be said to appear in the pupal stage (but we will show that in insects with imperfect metamorphoses the line of demarcation between larva and pupa is not marked), and they only attain their full development some little time after the exclusion of the perfect insect. A wing consists of an upper and lower membrane (readily separable in a recently excluded insect, or afterwards by maceration), strengthened by more or less numerous strong ribs, more or less connected transversely, termed nervures or veins (neither term being very appropriate), which are chitinous tubes (containing special tracheæ), through which the blood circulates. The varying condition of the wings will be alluded to in the systematic portion of this article, as also to some extent the scheme of neuration, one of the most important factors in systematic entomology, but rendered unsatisfactory in consequence of the utterly different nomenclature employed by writers on special orders, though doubtless the general scheme is capable of being homologized.

The last of the three great divisions of the body is the abdomen, which consists of a number of segments (normally nine), having an upper (dorsum) and lower (venter) chitinous surface, which two surfaces (in the most characteristic condition) are connected by a membranous lateral line, with lateral stigmata or spiracles. But almost every conceivable modification is presented both in its attachment to the thorax, its general outline, and the number of segments present. Of the appendages of the abdomen it is necessary to say but little. In a perfect insect there are no abdominal legs, and rarely any indications of breathing plates (so usual in some groups of aquatic larvæ). The appendages are therefore almost entirely connected with the sexual apparatus, which vary enormously, and occasionally there are terminal articulated thread-like tails, strongly simulating antennæ both in form and structure.

Nervous System.—This may be said to consist of a more or less double cord lying along the ventral portion of the body, connected at intervals by thickened masses termed ganglia. But the large mass in the head is termed the brain, in contradistinction to the others. The brain usually consists of a bilobed mass giving off nerve masses to the eyes, and threads to the other cephalic appendages or organs; recent researches prove that, at any rate in some cases, the brain has convolutions analogous to those of the higher animals. Immediately below the brain is a large ganglion, usually termed the infra-œsophagal, connected with the mouth organs and digestive functions. Then follow, in the thorax and abdomen, a series of ganglia, each of which gives off numerous lateral threads. But the number of these ganglia varies very greatly, not only in insects of different orders, or in species of the same order, but also in the larvæ, pupæ, and perfect insects of the same species; and it is impossible to enter here into the most rudimentary analysis of these variations. It has been said that normally there should be a ganglion for each segment (or for each movable segment) of the body, and to some extent this would appear to hold good, for, in those insects in which some of the segments coalesce, a similar arrangement is seen in the system of ganglia, but this would not appear to be a universal law, and in some the abdominal ganglia are virtually obsolete. Similar variations exist in the extent to which the double central column becomes united or remains divided. In addition to this column, a simple sympathetic nerve is also distinguished, without ganglia, but giving off threads to the respiratory and other systems. This lies above the main ganglionic chain. In minute structure the nervous cord of the *Insecta* is analogous to that of higher animals. The simplicity of the nervous system has caused it to be believed that insects do not suffer pain in the sense of that experienced by higher animals, and their behavior when subjected to treatment that should cause intense pain, in the ordinary sense of the word, appears to warrant such an opinion; but the existence of such a condition cannot be held to justify wanton cruelty. Those who desire minute information on the nervous system should especially consult Newport's article "Insecta" in Todd's *Cyclopœdia of Anatomy and Physiology*, and a series of articles by E. Brandt, now appearing in the publication of the Russian Entomological Society.

Respiratory System.—Respiration by tracheæ is one of the main characteristics of an insect. Tracheæ are tubes ramifying in the interior of the body, the walls of which are composed of two membranes with a spiral thread between, and extending into the wings and other appendages; but in the perfect insect the main tracheæ are subject to modification, and are more or less expanded into vesicles to suit the requirements of creatures with great powers of flight, or of strong movement in other ways. The manner in which air is communicated to these tracheæ, in order that the necessary oxygen may be obtained from it, is two-fold in its nature. In insects that live in free air the latter is received through lateral openings termed spiracles or stigmata, which vary in number in different insects, but there is usually one on each side of most of the segments. A spiracle usually consists of a longitudinal slit in a membrane, protected by delicate mechanism, and also by special muscles, which can close it hermetically if necessary. Many aquatic insects also breathe through spiracles, and in these cases a quantity of air is collected (or entangled) in delicate pubescence on the surface of the body, the insect coming to the surface to obtain a fresh supply at intervals. But in the majority of aquatic insects, and especially of their larvæ or pupæ, air is obtained by means of external threads or plates, expansions of the integument, the function of which is to absorb air from water and convey it to the tracheæ by means of delicate ramifications of the tracheal system in their substance. The number and position of these external appendages (or branchiæ) is as varied as are the conditions under which the insects live; in some only a single elastic tube is present, which can be protruded to the surface of the water, and its length adapted to the varying depth of that element; in some (as in many dragonflies) the plates are in the rectum, and the air is obtained by the forcible taking in and expulsion of water by means of powerful anal valves (which serve also for locomotion). It is obvious that those larvæ that exist parasitically in the substance of the body of other larvæ, etc., must still obtain air, and it is presumed that this is sometimes effected at the expense of the respiratory system of their hosts. It has long been known that rudimentary branchiæ exist in aerial insects, and, though this was at one time supposed to be an attribute of one or two forms only, it is now known to occur frequently. According to the researches of Gegenbaur and Palmén, those branchiæ exist side by side with the ordinary spiracles; hence they conclude that there is no direct connection between the branchial system of the larva and the spiracles of the imago. It is still perhaps an open question whether these branchiæ in the imago serve any functional purpose.

Alimentary and Digestive Systems.—The food of insects is either solid or liquid, and the parts of the mouth are modified, according to requirements, into two main conditions, termed mandibulate and haustellate; but the latter term is somewhat vague, inasmuch as the modifications are by no means homologous in all haustellate insects, although the structure is subservient to the same function. Again, in both divisions the food may be either vegetable or animal in its nature, and according as this may be the parts of the digestive system are modified. The most simple digestive system consists merely of a tube extending from mouth to anus, with no very distinct division into parts. But in insects the arrangement is considerably more complex, yet varying enormously. The most complete system consists of œsophagus, with the salivary glands (modified into silk-producing glands in *Lepidoptera*, etc.), crop or proventriculus, gizzard, stomach, small and large intestines, and an arrangement of small canals termed the Malpighian tubes. Some authors distinguish also other divisions of the intestines answering to those of higher animals. By some the term proventriculus is applied to the crop, by others to the gizzard. The gizzard is usually absent in haustellate insects; but, as most of these are truly mandibulate in their larval stage, much modification is undergone during metamorphosis. The digestive secretion of all parts of the system appears to be essentially alkaline, and assimilation goes on from all (excepting perhaps the lower intestine) *pari passu* with digestion, the latter being commenced in the crop. The Malpighian tubes are a set of long slender vessels (varying much in number) situated in the lower portion of the system at the junction of the small and large intestines. Their function has been warmly contested amongst physiologists, many considering them biliary organs, while probably an equal number maintain they are solely urinary, and a few hold that both these functions may be attributed to them. The recent researches of Plateau and others are in favor of their being solely urinary. Von Siebold has asserted that the biliary system consists of certain cells in the walls of the stomach. It is possible the whole intestinal canal is at times called upon to play a rôle quite independent of digestion and assimilation; it may be made subservient to metamorphosis through being distended with air, thus assisting the rupture of the integuments for the escape of the imago; but this can probably only obtain in insects with incomplete metamorphoses.

Circulatory System.—Almost as much uncertainty exists, or has existed, as to the true nature of this system as in other points of internal structure and physiology. Originally it was believed that no circulatory system existed, an idea that was speedily dissipated. If we examine a larva of which the integuments are tolerably transparent, we perceive, even without dissection, a large vessel running along the dorsal portion of the creature just beneath the integument, and we perceive also that it distinctly pulsates. This is the "dorsal vessel" or "heart," and it terminates anteriorly in a cephalic aorta. Examined more minutely by dissection, it is seen to consist of a number of chambers and constrictions, each chamber having a lateral valvular opening on either side, through which the blood is received into the vessel by regular currents and conveyed to the cephalic aorta, whence it escapes into the body in currents which have no vascular walls, and is again received into the dorsal vessels from lateral currents,—such, at least, is the most generally received opinion. Certain it is that the blood (which is ordinarily a colorless liquid) circulates through all parts of the body, even to the antennæ, legs, and wings, and the circulation can be well observed in the wings of some insects in which these organs are unusually transparent, in that case distinctly following the course of the nervures. But many physiologists have believed that the blood is conveyed over the body by means of the tracheæ, some distinguishing certain tracheæ to which this function alone, and not that of respiration, is proper. The majority of these, however, state that the blood simply flows between the two integuments of which the walls of a trachea are composed, and to this system the term "peritracheal" has been given. According to the results obtained from the experiments of the most recent observers, we prefer to doubt the existence of this peritracheal circulation. The relative frequency of pulsations varies much according to the insect and its state of activity or excitement. They disappear almost entirely in insects in a state of hibernation, and are much reduced in the pupæ of those that undergo complete metamorphoses.

Muscular System.—The muscles are attached to the inner side of the chitinous integument, and lie just beneath it. They are composed of numerous parallel fibres without any tendinous sheaths, but the fibres are apparently sometimes united at their extremity into a kind of tendon, which has been considered as only an extension of the chitinous integument. According to their position and function, they act variously, as do those of higher animals, and have received similar names. Their number is often enormous, and when we consider the great powers of flight, or of locomotion by other means, possessed by many insects, it is not difficult to understand that their strength must be proportionately great. Lyonet's celebrated treatise on the anatomy of *Cossus* remains a masterpiece of research on this subject, and in England Lubbock's recent memoir on the subcutaneous muscles of *Pygæra bucephala* is equally remarkable, and should be studied by those desiring minute information on the complex muscular system.

Generative System.—In all insects the sexes are separate. True hermaphrodites do not exist, though individual monstrosities, in which the form, coloration, and even internal organization of both sexes are combined, are not rare. The external organs are placed at or near the extremity of the abdomen, and are usually accompanied by secondary or accessory appendages often of most complex structure, serving to ensure complete contact during the sexual act, and probably also to some extent excitatory. In the dragon-flies, however, the intromittent organ of the male is in the under side of the second abdominal segment, which explains the extraordinary position of the sexes when coupled. In the male the testes are very varied in form, ordinarily separated, but sometimes united into one mass, each of the two halves of which has its special duct. But the separate form is by far the most usual. As in higher animals, there are the usual parts, the *ductus ejaculatorius*, the *vesiculæ seminales*, and the *vasa deferentia*, the conditions of which vary infinitely in different insects. Whether the intromittent organ is always traversed by an inner canal or not is a little doubtful. Ordinarily such is no doubt the case, but in others it would appear probable that the *ductus ejaculatorius* does not end absolutely in the organ, and that a groove on the surface of the latter receives the sperm. Some such arrangement must certainly exist in dragon-flies, in which the testes and the opening of the duct have no direct connection with the intromittent organ. In the female the ovaries occupy much of the abdomen that is not taken up by the intestinal canal. Each consists of a very varying number of tubes, branching off externally, in which the eggs are contained; these eggs are conveyed by oviducts, and before extrusion receive the fertilizing fluid stored in the spermatheca, which latter may be simple or compound; they pass out by the vagina. In close connection with these parts in the female is the poison gland and sting found in some insects. In the gravid female of *Termes* the ovaries become enormously distended, so that the entire insect may be said to consist of little else than eggs. The rudiments of the sexual organs may be detected in the larva when in a very young state, and the sex of the future perfect insect determined,—a sufficient answer to those who assume that sex can be controlled by the nutriment furnished to the larva. It was formerly considered that, pairing once effected, the male died almost immediately, and the female followed after having deposited her eggs. Recent observations go to prove that this is to a large extent erroneous, that pairing may be effected several times by both sexes (the female laying her eggs intermittently), in effect that polygamy and polyandry exist.

There are certain anomalous conditions of the generative system that may be conveniently noticed here, under different headings.

Neuters or Workers.—In bees, wasps, and ants, and also in *Termes* (or white ants), the majority of the members of a colony is made up of individuals which as a rule have no reproductive powers. In the first three, these are aborted females, and it has been proved (at any rate for ants) that occasionally these workers lay eggs, which, however, always produce males, the production of a queen depending apparently upon special feeding in the larval stage. In *Termes* the conditions are different. There are both workers and soldiers, both incapable of reproduction, but not exclusively consisting of aborted females, since both sexes are represented. Also in *Termes* there are what have been termed complementary males and females, distinct from the pair that were once supposed to be the exclusive founders of a new colony; of these the females lay comparatively few eggs, their ovaries not acquiring the extraordinary development of those of the true queen.

Viviparous Insects.—Oviparous generation is the rule in insects; but there are certain departures from the rule. In the *Aphides* it is well known that both the oviparous and viviparous exist in the same species. In *Lepidoptera* there is a well-authenticated instance of an Australian insect closely allied to the clothes-moth bringing forth larvæ already hatched. A similar condition is asserted to exist in a species of cockroach. In *Coleoptera*, Schiödte has noticed that two species of *Staphylinidæ*, living in the nests of white ants in Brazil, are viviparous, as is likewise *Oreina* in *Chrysomelidæ;* so also are the *Strepsiptera.* In *Diptera* flesh-flies of the genus *Sarcophaga* are known to be viviparous. But the most extraordinary instance is in certain minute flies, to be noticed below, of which the larvæ produce living larvæ.

Alternation of Generations, Parthenogenesis or Agamogenesis.—In the bee, ant, many gall-flies, some *Lepidoptera* and (as is now known) also some *Coleoptera*, and insects of other orders, females are capable of producing fertile eggs without any contact with the male, and the produce of these eggs is frequently male. This property varies considerably in details. In the case of the bee or the ant, it would appear that one impregnation suffices for the life of the queen (which may last for seven or eight years), but the power of producing females does not probably extend beyond the immediate influence of the impregnation. In some hymenopterous gall-flies a true alternation probably sometimes occurs, combined with dimorphism: but absolute parthenogenesis, in which females are produced generation after generation, is the common condition in many lepidopterous insects. This process is effected by internal budding. In the *Aphides* the conditions are still more remarkable, owing to the existence of both winged and apterous forms of both sexes, and of both oviparous and viviparous generation; but it is not proved that the same individual insect is capable of producing both forms. In the case of the minute fly (*Miastor metroloas*) mentioned above, the production of larvæ from larvæ is continued throughout the winter and spring, until in June the brood goes through its ordinary metamorphosis, and results in mature males and females, and so the cycle recommences. Of all the marvels in the history of insects, this is the most astonishing; no wonder that the assertions of R. Wagner (the discoverer) were met with incredulity from the best physiologists until abundantly confirmed by others, and in other species.

Metamorphoses.—Hundreds of volumes have been written on this fascinating subject, one or more of which are in almost every library; hence there is no necessity for giving more than a rudimentary outline here. All true insects may be said to undergo a metamorphosis. Such a condition is absent in the small groups known as *Thysanura* and *Collembola;* and, although these are here retained amongst *Insecta* as a matter of convenience, the writer is disposed to agree with Lubbock that they are outside the pale of true insects. Metamorphosis may be broadly grouped into two main divisions—(1) that in which the larva changes into a pupa which, as a rule, is inactive, and which never eats, and (2) that in which there is no true pupa state, the animal continuing active, and eating, from the egg to the perfect insect. In the former the larva changes its skin, or moults, several (often many) times before it changes to the pupa, the last moult (or ecdysis) happening when it is in what may be called the pseudo-pupal condition (which may last from a few hours to several months) immediately before the pupa state is assumed; this division is usually characterized as "metabolic." In the latter ecdysis goes on continuously at intervals from the egg to the winged-insect, and the form of the larval condition much resembles that of the perfect, the wings budding out gradually as the creature approaches maturity; the term "hemimetabolic" is applied to this division. In the first division the conditions are rather more varied than in the second. In the pupa of some *Diptera* the larval skin hardens, and within this the true pupa is formed (such a pupa is termed "coarctate"); in other *Diptera* the pupa is not contained within the larval skin (which much resembles a true cocoon), but is free and even sometimes active, the various appendages not being connected with the body, as is usually the case in that of a lepidopterous insect. The pupæ of *Hymenoptera* and *Coleoptera* are also much in the same condition, but they are not strictly active. Many writers have attempted to draw a broad distinction between such a pupa as that of a moth and that of an ant-lion or caddis-fly, cited here as extremes, because in the latter the members are free, and the pupa is really active shortly before the change into the perfect state, and thus the metamorphosis is supposed to be in some respects intermediate between that of true *Metabola* and true *Hemimetabola.* But such distinctions are more apparent than real. In many of the small moths the limbs and other appendages are scarcely consolidated with the body, but simply concealed in sheaths of which the ends at any rate are free. Also in the second (or hemimetabolic) division distinction has been drawn between the larva of a May-fly and that of a bug (as instances), because the changes from an absolutely apterous condition to one in which the wings are rudimentary and from this to the perfect state are more marked in the latter. This is probably due to the number of moults being less; the form with rudimentary wings is in no way a true pupa.

The metamorphosis of the internal organs, and even of the mouth parts, is much more marked in the *Metabola* than in the *Hemimetabola.* Respiration is maintained by means of spiracles or branchiæ, as in larvæ.

"Hypermetamorphism" is a term applied to certain conditions in which the larva at one period of its life assumes a very different form and habit from those of another period. Such a condition exists in several *Coleoptera*, such as *Meloe* and *Cantharis*, in which the larva is at first very active, with long legs, slender form, and anal setæ, and attaches itself to the bodies of bees, afterwards becoming almost apodal, short, and stout, and living in the bees'-nests. Other *Cantharidæ* live in the egg-tubes of *Orthoptera.* In *Sitaris* a still more remarkable intermediate condition has been observed: the larva after having attained its second condition assumes that of the coarctate pupa of a fly, from which it changes again to a state more analogous to the second condition before finally transforming to a pupa. This kind of metamorphosis has been closely observed by Newport, Fabre, Lichtenstein, Riley, and others. Brauer has recorded a somewhat similar condition in the larva of *Mantispa* (*Neuroptera*), which is at first free and very active, and afterwards becomes nearly apodal and obese, and lives parasitically in the nests of spiders. Advanced evolutionists hold the idea that larvæ are only acquired conditions.

Classification.

It is necessary to reduce what may be termed the systematic portion of this article to the smallest possible limits. The various orders are noticed under separate articles, and similar articles are devoted to the consideration of many of the more prominent, interesting, and familiar insects. All we can do here is to allude briefly to classification as a whole, with indications of the higher groups under each order. We also have nothing to do here with *Crustacea*, *Arachnida*, and *Myriopoda*, now considered as distinct classes, although American writers have recently again included the last two in *Insecta* as orders, placing the more subordinate groups (or orders in the general acceptation of the term) as suborders. Still more impossible is it for us to enter into an examination of the history of classification; those of our readers who are specially interested in this subject cannot do better than consult vol. iv. of Kirby and Spence's *Introduction to Entomology*, where a most full and painstaking "history of entomology" is to be found up to the date (1826) at which it was published; or they may consult with equal advantage Westwood's *Introduction to Modern Classification*, and Burmeister's *Manual of Entomology* (Shuckard's English translation). The different classifications proposed by authors mainly resolve themselves under three headings,—the "metamorphotic" (of which Swammerdam may be considered the founder), the "alary" (or wing-system, due to Linnæus), and the "cibarian" (or mouth-system, originating with, or at any rate elaborated by, Fabricius). The metamorphotic system divides insects into those that undergo complete and incomplete metamorphoses; the alary is based upon the presence of two or four wings, or their absence altogether; the cibarian depended upon the conditions of the mouth organs, and more especially as to their being fitted for biting or sucking (mandibulate or haustellate). But experience proved that each of these systems had its defects; there were always some groups, of more or less importance and extent, that would never fit satisfactorily into any of the proposed systems. To remedy this varying means were adopted, such as a combination of the several systems into what has been termed the "eclectic" system, the erection of numerous orders for certain aberrant groups, and that most ingenious idea of MacLeay, the author of what is termed the "circular" system.. We are disposed to consider that of all systems the one that combines the greatest amount of convenience with the nearest approach to being natural is the metamorphotic, and this we shall accordingly follow here. It is not intended to acknowledge the subsidiary orders, excepting the *Collembola* and *Thysanura*, which are probably scarcely true insects, but which it is necessary to place here, were it only to avoid the risk of their being overlooked altogether, inasmuch as the writers on the other classes of *Arthropoda* are not likely to recognize them as coming within their scope.

The stumbling-block of all systems has been the Linnæan order *Neuroptera*, inasmuch as its members combine the characters of most of the other orders, and ingenious American writers have attempted to overcome this difficulty by considering it a collection of "synthetic types." In adopting metamorphosis as the basis of classification, we prefer to take another course, and to follow Erichson, who (in 1839) boldly transferred all those *Neuroptera* with incomplete metamorphoses to the *Orthoptera* as a suborder, although, in dealing with the *Neuroptera* in the light of a specialist, division into several orders appears the more natural course.

The sequence of orders we propose to follow is as under:—

Metamorphoses complete (*Metabola*).	HYMENOPTERA.	
	COLEOPTERA.	
	DIPTERA.	*Genuina.* *Pupipara.* *Aphaniptera.*
	LEPIDOPTERA.	
	NEUROPTERA.	*Trichoptera.* *Planipennia.*
Metamorphoses incomplete (*Hemimetabola*).	ORTHOPTERA.	*Pseudo-Neuroptera.* *Genuina.*
	HEMIPTERA.	*Heteroptera.* *Homoptera.*
No metamorphoses (*Aberrant Insecta*).	COLLEMBOLA.	
	THYSANURA.	

The obvious innovation in this arrangement is the position assigned to the *Diptera*, rendered necessary by the intimate relationship of *Lepidoptera* and *Trichoptera*, but in a metamorphotic sense no particular outrage on more generally adopted systems is occasioned, and we see no alternative other than that of widely separating the two subdivisions of *Neuroptera*.

HYMENOPTERA.—In accordance with the system adopted by many modern writers, this order heads the scale as containing amongst its members those insects that appear to be endowed with the highest intellectual faculties. But at the same time it must be remembered that if the economy of the *Termitidæ* in the *Pseudo-Neuroptera* had been as fully investigated as has that of bees, wasps, and ants, it is probable that the importance of this idea might be considerably weakened. The main characteristics are as follows:—

Wings four (frequently absent altogether in ants, etc.), membranous, naked, transparent, with open reticulation and very few transverse nervules. Mouth mandibulate. Metamorphosis complete, but the pupa has its members free. Larva mostly apodal, but in the saw-flies much resembling that of *Lepidoptera*.

A convenient subdivision into three great groups is generally adopted, viz., *Aculeata*, *Entomophaga* (or *Pupivora*), and *Phytophaga*.

The **Aculeata** may be again divided into four:—*Mellifera* (or Bees), *Fossores* (Wasps, etc.), *Heterogyna* (Ants and allies), and *Tubulifera* (Ruby-tailed Flies), but the last is perhaps more generally considered as forming a special division. In these the females (and workers, when present) are provided with a sting at the apex of the abdomen, connected with a poison gland. The abdomen is petiolate. The antennæ are mostly thirteen-jointed in the males and twelve-jointed in the females. In the bees the mouth parts are greatly modified, so as to form a suctorial apparatus, by the elongation of the maxillæ, labium, and lingua, the small palpi being borne at its end. The neuration of the wings is tolerably complete. The legs are much modified, according to requirements, such as pollen-gathering, burrowing, etc. The larvæ are apodal, hatched in cells constructed by the parent insects, the food usually provided by them being either honey or other insects. The habits of the group are frequently social (in this case neuters or workers are present); many are parasitic on insects of their own group (in the broad sense), and in many instances the parasites strikingly resemble those species in the nests of which they live (as in the familiar instance of *Bombus* and *Apathus*). Each division includes several families (to which we cannot allude here), and the group as a whole includes some of the most familiar insects, such as bees, wasps, and ants.

The **Entomophaga** are invariably true parasites in the larval stage (excepting the *Cynipidæ*), the perfect insects depositing their eggs in or on the larvæ or eggs of other insects, and their larvæ living upon the adipose tissue or contents of the eggs. There are no true sting and poison gland, but the female usually has the end of the abdomen provided with a long slender ovipositor, with which she can (in some cases) pierce the skin if roughly handled (but no inflammatory symptoms follow). The antennæ are usually long, slender, and multiarticulate. The abdomen is strongly petiolate. The neuration of the wings is variable (often almost absent). The main divisions are *Ichneumonidæ*, *Proctotrypidæ*, *Chalcididæ*, and *Cynipidæ*, chiefly founded on the neuration, which in *Chalcididæ* (and in a lesser degree in *Proctotrypidæ*) is almost absent. Many members of this group are of extreme interest in consequence of their economy, and especially some extremely minute species (in *Proctotrypidæ*) that infest the eggs of other insects, some of which can swim by means of the wings in search of the eggs of aquatic insects. The *Cynipidæ*, although agreeing in main points of structure with the other divisions, are totally different in habits, and the term *Entomophaga* as applied to them is erroneous (a few, however, are parasitic upon aphides). They lay their eggs in the tissues or buds of plants, and there results therefrom a swelling termed a gall, inside which the larvæ feeds, either solitarily, or many in one gall in separate cells.

True Phytophagous *Hymenoptera* (or **Terebrantia**) comprise the two divisions known as *Tenthredinidæ* and *Siricidæ*. In these the abdomen, instead of being petiolate, is sessile; the female is provided with a double saw in the *Tenthredinidæ*, and with a borer in *Siricidæ*. The antennæ have seldom more than ten joints. The neuration of the wings is complete. The larvæ differ from those of all other *Hymenoptera* in possessing well-developed thoracic legs, and in addition (excepting in the *Siricidæ*) a varying number of abdominal prolegs, and are so like those of *Lepidoptera* as often to require a practised eye to distinguish them therefrom. All are phytophagous, but their habits are very varied; in fact, all the conditions known in *Lepidoptera* are probably here present also. Some species cause galls. Some (such as the Turnip Saw-Fly) occasion great damage. The *Siricidæ* are wood or stem borers; the familiar *Sirex gigas* often appears in the midst of large towns, through the larvæ or pupæ having been brought in with pine timber.

COLEOPTERA.—This is probably the largest, and certainly the best studied, of all the orders.

Four-winged insects, but the upper pair of wings are modified, hard and horny in texture, and are termed "elytra," lying longitudinally over the meso- and metathorax and abdomen, and when closed divided by a line or suture (occasionally the elytra are united, and in this case the second pair of wings is usually absent, and the insects are incapable of flight; more rarely the wings are absent altogether, both the elytra and hind-wings). Mouth mandibulate. Antennæ seldom more than 11-jointed (often much less). Metamorphosis complete; the pupa having its members free. Larva extremely variable as to form; usually with thoracic legs, sometimes apodal.

Latreille divided the enormous amount of materials comprised in this order into four great groups according to the number of joints in the tarsi. Thus the *Pentamera* have five joints in all the tarsi; the *Heteromera* have five in the anterior and intermediate tarsi, and four in the posterior; the *Tetramera* have four in all the tarsi, the *Trimera* three in all. More minute investigation and better knowledge have proved, however, that this system is essentially artificial, and in part founded on misapprehension; and it is the custom amongst many modern entomologists to ignore these great divisions, and to consider the order as composed of about 75 families, without collecting them into larger groups. It would be impossible to notice here each of these families in detail, and the old system, still regarded with favor by some of our most intelligent coleopterists as the most useful, will be followed.

The general structure is so marked that but little controversy has been occasioned. A beetle is recognized as such universally, notwithstanding the great diversity of details that exists. The only disputed elements are the *Strepsiptera* (Bee-parasites) and *Platypsylla* (an epizoic parasite on the beaver). The diversity in the larval condition is much greater, and as extremes may be cited the larvæ of the *Staphylinidæ* (in which there is little difference in form and structure from those of the imago, excepting the absence of wings) and the apodal maggots of the *Curculionidæ*. In the pupal condition this divergence mainly disappears.

The **Pentamera** are usually considered to comprise the following superior subdivisions. *Adephaga* alone possess an inner palpiform lobe to each maxilla; the larvæ are predaceous, and feed on other insects and on flesh generally; they include the *Cicindelidæ* (Tiger-Beetles) and *Carabidæ* (these two groups often termed *Geodephaga*), which are terrestrial, and the *Dytiscidæ* and *Gyrinidæ*, familiar aquatic groups, with the addition of *Amphizoa*, an anomalous American genus, recently referred to *Dytiscidæ*. *Palpicornia* have short clavate antennæ, and comprise a number of small and mostly aquatic genera. *Brachelytra* (including *Staphylinidæ*, known as Rove-Beetles or Devil's Coach Horses) are known by the very short elytra (usually much shorter than the abdomen), and form an exceedingly numerous group of often minute insects, of which the larvæ are predaceous, and differ but little in form from the imago; with these the curious and aberrant *Pselaphidæ* are usually united. *Clavicornia* have clavate antennæ, and are sometimes termed *Necrophaga*, from the habit many of the species have of feeding upon dead and decaying animal matter; the forms are very numerous, and include the well-known Burying Beetles (*Necrophorus*) and the destructive *Dermestidæ* (in which is the Bacon-Beetle); *Parnidæ* are aquatic; *Paussidæ* are wonderfully curious creatures with singularly formed antennæ, living in ants' nests: in this division are now placed the almost microscopic *Trichopterygidæ*, most of which are not larger than small grains of sand, and remarkable for their narrow ciliated hind wings, and also other groups sometimes placed in the *Trimera*. *Lamellicornia* have the apex of the antennæ pectinate or provided with lamelliform plates: they include the Stag-Beetles and the very numerous Dung-Beetles, amongst which is the *Scarabæus* of the Egyptians, together with the numerous Chafers. *Sternoxi* have the prosternum produced and pointed, and mostly filiform antennæ, with ordinarily an elongate oval form: in this division are the beautiful *Buprestidæ* and the familiar *Elateridæ*, the latter known as Click-Beetles, and able to spring by means of the process of the prosternum acting on a peculiar structure of the mesosternum: the larvæ are all vegetable feeders, and have the legs only slightly developed; those of *Elateridæ* are known as Wire-Worms, and are often very destructive; some of the exotic *Elateridæ* are brilliantly luminous. *Malacodermi* are a group of mostly soft-bodied insects very variable in form and habits; the prosternum is not produced, and the antennæ are usually pectinate or serrate: included in it are the *Telephoridæ* (Soldier-Beetles), *Lampyridæ* (Glow-Worms), *Cleridæ* (often parasitic in the nests of bees), the wood-eating *Ptinidæ* (in which is *Anobium*, or the Death-Watch), and *Bostrychidæ*.

The **Heteromera** are a large group of forms connected together by the tarsal structure, but otherwise of the most diversified nature; in fact it may be said that, so far as outward appearance is concerned, there are forms in it that might be readily mistaken as belonging to almost all the other principal groups, so protean are they both in structure and in habits. Two principal points of structure have been used for separating them into two great divisions. In one of these they have been divided into *Globicoxæ* and *Conicoxæ*, according to the form of the anterior coxæ; in the other the two divisions are termed *Atrachelia*, in which the head does not form a neck, and *Trachelida*, in which the head is narrowed into a neck. To some extent both these points of structure are correlated; we adopt the latter; but it must be remarked that the protean nature of the group as a whole is equally exemplified in its primary subdivisions. They appear to be invariably terrestrial, and for the most part phytophagous. The *Atrachelia* are mainly composed of a large number of genera of which *Tenebrio* (the Meal-Worm) may be taken as a type, and *Blaps* (the Churchyard Beetle) is also amongst its members. In the *Trachelida* the forms are more varied, and include some of the most remarkable instances of anomalies of form and structure, and even of metamorphosis, that exist amongst *Coleoptera*. Here are placed the *Cantharidæ* (Blister-Beetles, etc.), so remarkable for the hypermetamorphosis that exists in the larvæ, and parasitic in the nests of bees and locusts; the extraordinary genus *Sitaris* (equally hypermetamorphotic), a parasite in bees' nests; *Meloe* (the Oil-Beetles, the history of which reads almost like a romance, the very young larvæ being active little creatures living on the bodies of bees, but afterwards becoming obese and almost footless, and feeding on the bee larvæ in the nests); and *Rhipidius*, parasitic on cockroaches. As a crowning point of eccentricity the extraordinary *Strepsiptera* (or *Stylopidæ*) seem likely to find their resting place here, after having been considered a distinct order, as *Diptera*, as *Hymenoptera*, and as *Neuroptera;* but even yet it is probable their position may be warmly disputed. These anomalous creatures are parasitic in the bodies of bees, and the female, which is vermiform, and without antennæ, legs, or wings, never leaves its host, and is viviparous. The male has very large eyes, and extraordinarily short antennæ; the anterior wings (or elytra) are represented by small narrow processes, not unlike the halteres of *Diptera;* the posterior wings are folded in repose, but when expanded are extraordinarily broad, whitish in color, and almost without nervures. The metathorax occupies the greater part of the body; the abdomen is terminated by a short stout process. The very young larvæ are minute, active, and not unlike the young larvæ of *Cantharis* and *Meloe* in form, and escape from the body of the mother by a slit in the neck; they are conveyed into the nests of their hosts, and penetrate the larvæ of the latter, where they undergo hypermetamorphosis. Although originally supposed to be exclusively parasites on *Hymenoptera*, one species has recently been detected in the body of an homopterous insect.

Tetramera.—Although the beetles of this great division have apparently only four-jointed tarsi, it was long ago demonstrated by Westwood that there is actually a very minute joint between the lobes of the third joint, so that they are actually pentamerous, but the concealed joint is probably functionless; thus the terms *Pseudo-Tetramera* and *Crypto-Tetramera* have been proposed in lieu of *Tetramera*. The chief groups are the *Rhyncophora*, *Xylophaga*, *Longicornia*, *Phytophaga*, and *Clavipalpi*. All are vegetable feeders. The *Rhyncophora* (or Weevils) have the head produced into a rostrum, varying enormously in length, and in its lowest condition scarcely appreciable. The larvæ are footless grubs, feeding almost universally in the interior of the stems or seeds of plants, and occasionally causing galls. Some exotic members of this group are amongst the most beautiful of insects. A peculiarity exists in the antennæ, which are attached to the rostrum, and usually elbowed, the basal joint being ordinarily very long (and termed the "scape") and the rest shorter, the terminal joints usually forming a club (the portion between the scape and the club is termed the "funiculus"). *Rhyncophora* have been very variously subdivided. Schönherr separated them into *Orthoceri* and *Gonatoceri*, according to the absence or presence of an elbow to the antennæ; Westwood has three families, *Bruchidæ*, *Attelabidæ*, and *Curculionidæ*, founded on the antennæ and palpi; Lacordaire's groups are *Adelognathes* and *Phanerognathes*, founded on the covered or uncovered mentum. Adopting Westwood's system, we have three families. *Bruchidæ* have only a short flattened snout, unelbowed antennæ, and filiform palpi;

they are probably universally seed or nut feeders in the larval stage. *Bruchus granarius* causes great destruction to grain; species of the genus *Caryoborus* affect palm-nuts, some even living in the so-called vegetable-ivory nuts; *Anthribidæ*, which form a subfamily of *Bruchidæ* according to Westwood, live in dead wood. *Attelabidæ* have the antennæ unelbowed, the palpi conical, and the rostrum long and curved; the genera *Brenthus* and *Attelabus* form the types of two subfamilies differing chiefly in the form of the club of the antennæ; the first of these is almost entirely extra-European, and its members appear to feed on dead wood; the second includes the brilliant species of *Rhynchites* (the larvæ of which roll up leaves and feed on them, or live upon fruits) and the minute species of *Apion*, of which the larvæ variously attack seeds, the interior of the stems of plants, etc. *Curculionidæ* have elbowed antennæ and conical palpi, and are further subdivided into two main groups according to the length of the rostrum, each again forming numerous smaller groups; the family contains many of the most familiar weevils, and some of the most destructive; the habits are extremely diversified: *Sitophilus* feeds on grain, *Calandra* in the stems of palms, sugar-cane, etc., *Balaninus* on nuts, *Hylobius* on the wood of pine trees, and a multitude of other instances of peculiar habits might be cited. It must be remarked that other main groupings of *Rhyncophora* considerably modify both the sequence and family position of many genera to an extent that cannot even be glanced at here. *Xylophaga* form a small group sometimes united with the *Rhyncophora*, consisting of small wood-boring beetles, in which the rostrum may be termed obsolete, and the insertion of the antennæ is close to the eyes. Some of the members of this group (of which *Tomicus* and *Scolytus* are familiar examples) are supposed to cause great damage through their larvæ feeding beneath the bark of trees; but it is possible they only appear when an unhealthy condition has been set up from other causes. The *Longicornia* may be mainly distinguished by their elongate elegant form, long antennæ, which are generally filiform, but often pectinate, serrate, or ornamented with tufts of hair, the head not rostrate and armed with powerful jaws, the femora often clavate, and the tarsi having the basal three joints cushioned beneath. The larvæ mostly feed on dead or dying timber, boring into its interior, and but seldom on living healthy wood, the females being provided with an ovipositor; these larvæ are fat, with very strong mandibles, and extremely short legs; in some species several years elapse before they attain their full growth. The most modern classification recognizes three families, *Prionidæ*, *Cerambycidæ*, and *Lamiidæ*. The *Prionidæ* have the sides of the prothorax margined, and usually toothed, and comprise the largest known beetles in length, even if not in bulk. *Cerambycidæ* have the head porrect, and the prothorax not margined; some authors separate from these a family *Lepturidæ* as of equal value. *Lamiidæ* have the head vertical. The *Phytophaga* form a large group of beetles feeding essentially, in all their stages, on the leaves of plants (hence the name). They are usually of short and thick form, with filiform, moniliform, or serrate (never clavate) antennæ, the head ordinarily immersed in the prothorax and without rostrum, and the elytra covering the sides of the abdomen; the mandibles comparatively weak; the femora often enlarged. The larvæ are usually external feeders, with well-developed legs, and often very curious in form. Much diversity in the classification of *Phytophaga* exists, and as to the number of families and the value of their characters. By Latreille they were divided into *Eupoda* (*Parameca*, Westwood) and *Cyclica*, of which the most prominent character is in the external form, the *Eupoda* having the head and thorax narrower than the abdomen, whereas in the *Cyclica* the base of the elytra is not broader than the hinder part of the thorax, hence the form is more rounded. Another grouping is according to the insertion of the antennæ at the sides, or on the middle, of the front. The number of families varies from four to nine according to different authors. A glance at the prominent forms, according to later ideas, is here given. *Crioceridæ* (by some divided into *Crioceridæ*, *Donaciadæ*, and *Sagridæ*) belong to the *Eupoda*, and include the well-known Asparagus Beetle (*Crioceris asparagi*), the genus *Donacia* (and allies), which is aquatic in its earlier stages, and the brilliant exotic genus *Sagra* (remarkable for its enormously thickened hind femora), the larva of which forms galls on the stems of plants and lives therein. *Cryptocephalidæ* (including *Clythridæ*) are remarkable for the habits of the larvæ, which form hard cases of excrement (?) in which they live. *Chrysomelidæ* are a group of often beautiful insects, mostly remarkable for their nearly hemispherical form; they include, *inter alia*, *Timarcha* (the Bloody-nosed Beetle), the well-known genus *Chrysomela*, and the Colorado Potato-Beetle (*Doryphora* or *Longitarsus*); most of them distil an acrid fluid; the larvæ are short and obese, feeding exposed, and the pupæ often have the remarkable peculiarity of being suspended by the tail. *Halticidæ* are noted for their thickened hind femora and their jumping powers; though small in size, some of the members (*e. g.*, the Turnip-Flea) are most destructive. *Cassididæ* (or Tortoise-Beetles) usually have the sides of the elytra expanded; the larvæ have the very singular habit of concealing themselves under a covering formed of their own excrement, which is sustained by means of a forked appendage at the extremity of the body. Other families (such as *Hispidæ* and *Galerucidæ*) must be passed over. The last division of the *Tetramera* is the *Clavipalpi*, often placed with the *Trimera*, and forming a connecting link therewith. They are a small group, with the last three joints of the antennæ forming a compressed club, and the last joint of the maxillary palpi also broadly clavate. The family *Erotylidæ* mainly constitutes the group; the larvæ probably all live upon fungi. In proof of the wide divergence of opinion as to the relationship of special groups, it may be mentioned that one author places certain genera of this group amongst the *Clavicornia* of the Pentamerous division.

The last of the great divisions of *Coleoptera* forms the **Trimera**. As in the *Tetramera*, it was discovered that the term is not strictly applicable, and that a minute joint is concealed between the lobes of the second joint of the tarsi, hence they have been called *Pseudo-Trimera* and *Crypto-Trimera*. Some authors have made this group a place of refuge for many almost isolated forms, the natural position of which it is difficult to suggest. At present, however, only a small number of more homogeneous materials are usually located here, and these are divided into *Aphidiphaga* and *Fungicola*. The *Aphidiphaga* comprise the familiar Lady-Birds (*Coccinella*) and allies; these have the last joint of the maxillary palpi hatchet-shaped, have short-clubbed antennæ, and have the body remarkably hemispherical. They appear to feed chiefly on other small insects in both larval and perfect stages, and aphides are especial articles of diet with them; but the writer has seen a larva of *Coccinella* with its head deeply immersed in the juicy body of a recently-formed pupa of its own species. *Fungicola* have the last joint of the maxillary palpi filiform, with longer antennæ, and, as a rule, less hemispherical body. They contain a number of mostly small and little familiar forms, and, as their name indicates, are often found in fungi, on which they no doubt principally subsist.

DIPTERA.—Only the anterior (mesothoracic) wings present, membranous, usually naked, with varying longitudinal nervures and but few transverse nervules. Posterior wings replaced by knobbed filaments termed "halteres." Mouth consisting of a rostrum formed chiefly by the extended labium, forming a canal in which the other usual organs, modified into lancet-shaped pieces, are contained, the whole forming a sucker; only the maxillary palpi developed. Thorax consisting almost entirely of the greatly enlarged mesothorax, the two other divisions very small, and scarcely separable from the mesothorax. Tarsi 5-jointed; the end joint with a pair of more or less disciform pulvilli. Metamorphosis complete.

Although it is the generally received opinion that the halteres are the representatives of the posterior wings, there have been those who regard them rather as connected with respiration or hearing, and by some they have even been considered as belonging to the base of the abdomen rather than to the thorax; this latter idea results from the difficulty of defining the true limits of the metathorax. At the base of each anterior wing is a small membranous portion termed an "alulet," not absolutely connected with the wing itself, but which must be considered an adjunct, and certainly not representing a posterior wing.

Diptera form one of the most extensive orders. The *Genuina* are commonly divided into two great groups, according to the structure of the antennæ, and termed *Nemocera* and *Brachycera* respectively; but it has long been seen that these divisions are not natural, especially with regard to metamorphoses, and Brauer proposed division according to whether the larval skin at the last moult opens by a slit down the back or in a curvilinear manner, a proposal he has since extended by demonstrating that those two divisions—*Orthorhapha* and *Cyclorhapha*—are rendered the more natural by the pupal condition being correlated with differences in the larva and perfect insect, and eventually it is probable his views will be generally adopted. Another basis for division is according to whether the pupa is free (sometimes active, but not taking nutriment) or enclosed within the hardened skin of the larva ("obtected" or "coarctate"). The division into *Nemocera* and *Brachycera* is here followed.

In the **Nemocera** the antennæ are long and slender, and composed of a considerable number of small joints, which are often verticillate or plumose. They include the families *Culicidæ*, *Chironomidæ*, *Psychodidæ*, *Cecidomyiidæ*, *Mycetophilidæ*, *Tipulidæ*, and *Bibionidæ*, but some authors make a more minute subdivision. All these, and a multitude of others, fall into Brauer's suborder *Orthorhapha*, and the pupa is obtected. Here come some of the most familiar and bloodthirsty members of the order, such as Gnats (or Mosquitos), Midges, Gall-Midges, "Daddy Long Legs," etc., and some of them cause incalculable mischief to the agriculturist. In those species in which the earlier stages are aquatic, the pupa is active.

The **Brachycera** have the antennæ short and thick, not more than three-jointed, but the terminal joint has a bristle (*arista*), which is sometimes articulate. These again have been divided into *Hexachætæ*, *Tetrachætæ*, and *Dichætæ*, according to the number of setæ concealed in the mouth. They are "cyclorhaphous," and the pupa is coarctate. It is not possible to enumerate here all the families, nor to allude to the extreme diversity of habit and structure that exists. House-Flies, Blow-Flies, Flesh-Flies, Bot-Flies, and Gad-Flies, the beautiful *Syrphidæ* (many of which devour aphides in the larval state), the parasitic *Tachinæ*, the plant-eating *Phytomyzæ*, etc., all belong to this division.

The **Pupipara** are a small group distinguished especially by the fact that the larvæ and pupæ are developed in the body of the mother, and the head is sunk in the thorax; they have even been considered a distinct order termed *Homaloptera*. All are parasitic. They include *Ornithomyia* (Bird-Flies), *Melophagus* (the Sheep-Tick), the extraordinary wingless genus *Nycteribia*, parasitic upon bats, and the perhaps still more extraordinary genus *Braula*, a minute creature known as the Bee-Louse. Brauer terms them *Cyclorhapha pupipara*.

With the *Diptera* (as a distinct section) it is now the all but universal practice to include the **Aphaniptera** or Fleas, at one time considered as forming a distinct order. They differ from true *Diptera* in their laterally compressed form, well-defined thoracic divisions, absence of wings (which are represented only by scales), aborted antennæ, developed labial palpi, etc. The mouth of the imago is (as is too well known) formed for suction, and its parts can be homologized with those of the true *Diptera*. The larva is slender and worm-like, and is mandibulate, in all probability feeding on the scaly débris or scurf from the skins of the animals attacked; it is not found on the animals themselves, but in their beds or other resting-places. The pupa is inactive. For all practical purposes the *Aphaniptera* include only two genera—*Pulex* and *Sarcopsylla*, the Flea and the Chigoe or Jigger. Many mammals and some birds have each its own peculiar species of flea, or more than one, and the size of the tormentor is often in an inverse proportion to that of the tormented, the flea of the mouse being of gigantic proportions. The chigoe is notorious in tropical America for its habit of penetrating the skin of man, especially on the feet, the abdomen of the insect swelling and causing troublesome ulcers. Formerly it was believed that the eggs were deposited in the ulcers and that the larvæ fed therein, but more recent observations tend to prove that the habits are much those of ordinary fleas.

LEPIDOPTERA.—Four membranous wings (frequently rudimentary, or sometimes wanting, in the female) clothed with flattened striated scales; neuration open; transverse nervules few; at the base of the anterior margin of the posterior pair is frequently a bristle used for connecting the two pairs in flight. Mouth haustellate, the maxillæ being much elongated and very slender, forming two closely-applied pieces, which together make the suctorial apparatus by means of which the nectar of flowers is pumped up for food; in some groups this apparatus is rudimentary. Labial palpi strongly developed, the maxillary ordinarily rudimentary (but more developed than the other pair in a few small groups). Prothorax very narrow, with a pair of lateral organs termed *patagia*. Legs slender; tibiæ spurred. Metamorphosis complete, all the appendages of the pupa enclosed in common covering with the body, but leaving the parts visible (occasionally, in some of the lower groups, the extremities of the appendages are free). Larva (termed a caterpillar) with six thoracic legs, and with a varying number (never more than 4 pairs) of fleshy abdominal and two anal prolegs (rarely the larva is apodal). With few exceptions, they are phytophagous.

These insects are familiarly known as Butterflies and Moths, and the order contains the most beautiful insects that exist, and forms the most popular and attractive of all for collectors. The scales of the wings (and other parts of the insect) are really modified hairs. Each is a flattened sac, striated on one side, containing variously colored pigments, the arrangement of scales of different colors causing the beautiful markings and patterns so universal; but metallic colors are due also to interference caused by minute inequalities of the surface, combined with the contained pigment.

The classification of *Lepidoptera* is still in a state of much uncertainty. By collectors they are fancifully divided into *Macro-* and *Micro-Lepidoptera*. A more familiar division is into Butterflies and Moths,—the former being termed *Rhopalocera* (or *Diurni*), the latter *Heterocera* (or *Nocturni*).

The **Rhopalocera** are especially distinguished by their clubbed antennæ. The following great groups are tolerably well marked (but each has been much subdivided):—viz., *Papilionidæ*, *Nymphalidæ*, *Erycinidæ*, *Lycænidæ*, and *Hesperiidæ*. Some split the division into two, according as the pupa is suspended by the tail only, or has a thread round the body as well (these groups are termed *Suspensi* and *Succincti* respectively); the *Nymphalidæ* are especially characteristic of the first of these. In the *Nymphalidæ* the anterior legs are not fully developed in either sex; in the *Erycinidæ* and *Lycænidæ* this occurs only in the males. The *Hesperiidæ* have the club of the antennæ terminated by a hook, and the position of the wings in repose differs ordinarily from that in the other groups; the pupa is enclosed in a rudimentary cocoon, and may even be subterranean.

The **Heterocera** are subdivided roughly into *Sphingidæ*, *Bombycidæ*, *Noctuidæ*, *Geometridæ*, *Pyralidæ*, *Tortricidæ*, *Tineidæ*, and *Pterophoridæ*; but much more minute subdivision is adopted by specialists. In these the form of the antennæ is very variable (as the name implies), and the bristle on the posterior wings is usually (not always) present. The *Sphingidæ* (which comprise some of the largest and most robust moths) usually have the antennæ fusiform towards the tips. *Bombycidæ* generally have the antennæ of the male strongly pectinate, and those of the female simple or nearly so; the larvæ with four pairs of abdominal prolegs (and the anal pair); but this is a group of extremely heterogeneous materials, if taken in its widest sense; it includes the Silk-Worm Moths as familiar examples, and many extraordinary forms, amongst which may be mentioned the curious *Psychidæ*, in which the larvæ manufacture portable cases wherein they live, and in which the females are apterous. Perhaps allied to this group, or intermediate between it and the *Sphingidæ*, is the curious and abnormal collection of pretty insects termed *Castniadæ*, at one time considered to be butterflies, and even yet included with them by some authors. The haustellum is rudimentary in the true *Bombycidæ*. The *Noctuidæ* are stout-bodied moths, mostly (but by no means always) of nocturnal habits; the antennæ greatly varying, but not thickened; the bristle on the posterior wings present; the haustellum present (in one genus, *Ophideres*, it is strong enough to pierce the skin of oranges). They are mostly divided into two groups according to the number of the prolegs in the larvæ (four, or only three, abdominal pairs), and the neuration of the posterior wings. The larvæ are usually nearly smooth (those groups with hairy larvæ are by some transferred to the *Bombycidæ*), and the pupæ subterranean. *Geometridæ* are especially distinguished by the presence of usually only one pair of abdominal prolegs, occasioning a peculiar form of locomotion, termed "looping;" antennæ varying; bristle of posterior wings present; the wings usually expanded when at rest. With apparent relations to these is the small group *Uraniidæ*, consisting of beautiful papilioniform insects, still by some placed with the butterflies. *Pyralidæ* form a special group of varying, and for the most part rather small, insects, with simple (or nearly simple) antennæ; long slender legs; the bristle of the posterior wings present; long palpi; larvæ with three to five pairs of abdominal prolegs, and mostly smooth and glossy in appearance. *Tortricidæ* are small insects of nocturniform mien when at rest (the wings being horizontal and not expanded); antennæ simple; bristle of posterior wings absent; haustellum short; palpi short; larvæ with four pairs of abdominal prolegs. Many of the species of this group do immense damage to trees and garden plants. The *Tineidæ* is an immense group of mostly small (often very minute) insects, with extremely varying structure and habits. They may always be distinguished from the *Tortricidæ* by the long palpi (the maxillary pair being sometimes strongly developed and exceeding the labial); the fringes of the wings are usually very long. Some of these minute forms are excessively beautiful. The group as a whole is made up of very incongruous materials. *Pterophoridæ* are a small group at once distinguished by the wings being split up into linear divisions, hence they have been termed "plumes." By some they are not considered distinct from the *Pyralidæ*, with which there is considerable structural affinity.

NEUROPTERA.—Four membranous and for the most part densely reticulate wings, more or less clothed with hairs, but without true scales; very frequently the hairs are on the neuration only. Mouth mandibulate. Metamorphosis complete, but the pupa has its members free.

In the outline of classification (at p. 148) proposed to be adopted in this article, it is stated that the *Neuroptera* as there indicated are considered as forming a single order, more as a matter of convenience than from any conviction of the homogeneity of the two divisions.

The **Trichoptera** (or Caddis-Flies) form a very natural and sharply defined group distinguished by their rudimentary mouth-parts, with the exception of the two pairs of palpi, which are strongly developed, the maxillary pair being the longer, and with often the greater number of joints; the antennæ setaceous; wings with comparatively simple neuration and but few transverse nervules, ordinarily covered with hair (which sometimes simulates scales); larvæ (known as Caddis-Worms) with well-developed thoracic legs, and anal crotchets, but without prolegs, living in tubes covered with extraneous materials; pupa lying free in the case, or occasionally in a special cocoon, only active just before its metamorphosis; habits (with one or two exceptions) aquatic.

It is considered by the writer that there is direct relationship of the *Trichoptera* with the *Lepidoptera*, and this idea acts as the key to the scheme of classification adopted. They are divided into seven families, viz., *Phryganeidæ*, *Limnophilidæ*, *Sericostomatidæ*, *Leptoceridæ*, *Hydropsychidæ*, *Rhyacophilidæ*, and *Hydroptilidæ*, chiefly according to the structure of the maxillary palpi. In the *Rhyacophilidæ* and *Hydropsychidæ* the larvæ inhabit fixed cases, in the others the cases are free, and carried about by the inmates; in the *Rhyacophilidæ* the pupa is enveloped in a special cocoon. The neuration shows strongly-marked homology with that of *Lepidoptera*.

The **Planipennia** (or true *Neuroptera* according to modern ideas) have strongly-developed mandibulate mouths; for the most part moniliform or filiform (often clavate) antennæ; the wings ordinarily densely reticulate, with very numerous transverse nervules, the membrane hairless or nearly so. The larva is more divergent from the Lepidopterous type. The pupa is ordinarily in a cocoon; it is active just before its transformation. A convenient subdivision is into *Panorpidæ*, *Sialidæ*, and *Megaloptera*.

The *Panorpidæ* (Scorpion-Flies, etc.) are remarkable for the mandibles, etc., being situated at the end of a long beak, formed by the much-elongated clypeus above and the lower lip beneath. The wings have open reticulation, and the larva is more vermiform than in the succeeding groups, so that the relationship to the *Trichoptera* is close. They are carnivorous both in imago and larva, and the latter is subterranean. *Panorpa* is remarkable for the cheliform termination of the abdomen, *Bittacus* for its tipuliform aspect, *Boreus* for its nearly apterous condition.

The *Sialidæ* form a heterogeneous group of small subdivisions with setaceous antennæ (which are sometimes pectinate); strongly developed prothorax; the third or fourth joints of the tarsi cordate. They are again divided into two sections (or families), of which *Rhaphidia* and *Sialis* may be taken as the types. The former (Snake-Flies) are especially remarkable for the enormously elongated prothorax (the anterior legs at its posterior extremity); the larvæ sub-cortical. The latter comprise mostly large insects with strong (but not greatly elongated) prothorax and ample wings, the larvæ of which are aquatic, and provided with lateral branchial plates; the genus *Corydalis* is remarkable for the enormously elongated mandibles of the male (but not in all species).

Megaloptera contain many groups of insects, with mostly moniliform (or clavate) antennæ; densely reticulate broad wings; varying prothorax; tarsal joints not dilated. The number of subfamilies is large. The most prominent forms are the *Mantispidæ*, with their long prothorax (the anterior legs at its anterior end), the larvæ of which live in the nests of spiders (and also tree wasps), and in *Mantispa* undergo a kind of hypermetamorphosis; the *Nemopteridæ*, with their linear posterior wings; the Ant-Lions, with their clavate antennæ and trap-forming larvæ; the *Chrysopidæ* and *Hemerobiidæ*, known to feed on aphides in their larval stage,—the former often emitting a disgusting odor; and the very curious little *Coniopterygidæ*, covered with a whitish waxy secretion, and differing from all others in the extremely simple neuration. In *Osmylus* and *Sisyra* the larvæ are aquatic; and those of the latter have been found in the interior of the fresh-water sponge.

ORTHOPTERA.—Typically with four densely reticulate unequal wings (or apterous), whereof the anterior are more or less coriaceous, the posterior folded under them, and membranous; in the most typical groups they are deflexed, and closely applied to the body longitudinally in repose. Mouth mandibulate. Metamorphosis incomplete.

Having adopted metamorphosis as a basis for classification, it became necessary to view this order after the manner universal amongst German systematists, and to include in it many groups that are ordinarily accepted as neuropterous, the only plan possible without the erection of independent orders for their accommodation. The result is that more absolute homogeneity from a general point of view is attained, and we have to deal with an order made up of otherwise most incongruous elements, but somewhat relieved by the sharpness with which the great groups are defined. Regarding the two great divisions, *Pseudo-Neuroptera* and *Orthoptera genuina*, as a whole, the main distinction really consists in the fact that in the former the four wings are equally membranous, whereas in the latter the anterior pair are more or less coriaceous; another difference is in the head, which in the former is horizontal, whereas in the latter it may be described as vertical; but this distinction only applies to the typical groups. Thus there is really little more difference than exists between the two great divisions of *Hemiptera*, now almost universally placed in one order.

Naturally allowing the **Pseudo-Neuroptera** the first place as following on from the true *Neuroptera* (though some would say the Dragon-flies are really the typical *Neuroptera* of Linnæus), these must be first considered. Adopting the descending scale, the main groups may be glanced at as follows:—

The *Odonata* (Dragon-flies; constituted an order by Fabricius) may be considered the most highly organized, with regard to their powerfully mandibulate mouth, strong, densely reticulate wings, etc. The special peculiarities of this group (including the extraordinary structure of the mouth in the preparatory stages, and the anomalous position of the genital organs in the male) have been fully discussed in the article DRAGON-FLY (*q.v.*).

The *Ephemeridæ* (see EPHEMERIDÆ) follow. After these come the *Perlidæ*, aquatic insects in their preparatory conditions, remarkable for the comparatively weak development of the mouth parts (shared with the *Ephemeridæ*) in the perfect state, the four wings longitudinally horizontal and overlapping, the stout quadrate or oblong prothorax, the frequent presence of two articulated tails, the long setaceous antennæ, etc. This group is also remarkable as being the first in which the persistence of external branchiæ in the imago was detected (a peculiarity since found to be of frequent occurrence in them, and extending to other orders). They are known familiarly as Stone-Flies, and form a large portion of the stock-in-trade of an angler.

The *Embidæ* constitute a very small group, which in general form much resemble *Perlidæ*, but have, on the other hand, affinities with the white ants. The larvæ live habitually under stones in little galleries, and a recent discovery appears to prove that they feed on roots.

Termitidæ (or White Ants, placed by some authors in the true *Orthoptera*) are social insects living in immense communities, and forming nests on the ground or on trees. In some respects there is analogy between these and social *Hymenoptera*, and the diversity of condition in a single species is even greater. Winged forms of both male and female exist (the wings being shed at a certain time), and there are also commonly apterous forms known as workers and soldiers, whose office it is to build the dwellings and protect the inmates, the soldiers having the head provided with a powerful horn or elongated mandibles. Each condition has its own special immature form, so that it is probable no more specially polymorphic insects exist. The wings are carried horizontally and overlapping in repose; the prothorax is well developed, and the tarsi are four-jointed. Recent observations tend to show that specially prepared food (comminuted wood) is provided for the larvæ.

Psocidæ are a small group of small insects remarkable for their swollen face, setiform antennæ, narrow prothorax, and large mesothorax, four-jointed maxillary palpi, and rudimentary labial palpi, two or three-jointed tarsi. The wings are deflexed (often absent), with ordinarily very open neuration. These insects live on fungi and débris and also occasionally on dry animal substances, as in the case of the Book-Louse, ordinarily so abundant in neglected collections of insects, and erroneously supposed to occasion a ticking like that of *Anobium*.

There remain two groups the position of which has occasioned much controversy, but which are now often placed here, not, perhaps, because the affinities are very marked, but more to accommodate them with a resting-place in a division of *Insecta* the characters of which are so very elastic.

The first of these are the *Thysanoptera*, considered a distinct order by Haliday, the founder of the name, and by Burmeister placed in his order *Gymnognatha* as a distinct group termed *Physopoda;* by some authors they are placed in the *Hemiptera*. It is true that the mouth forms a short rostrum with only bristle-like mandibles, but the presence of distinct palpi would appear definitely to invalidate the position in *Hemiptera*. The wings are four in number, lying horizontally on the back and crossing at the tips; they are very slender, membranous, without nervures or nearly so, and strongly ciliated, or they may be wanting in some species, even in the perfect state. These insects are familiarly known as *Thrips*, and sometimes occasion much damage to various kinds of plants by sucking the juices, which the almost haustellate nature of the mouth enables them to do. They are mostly very minute insects, and have been divided into many sections and genera on structural characters.

The second of the above-mentioned groups is the *Mallophaga* (or Bird-Lice), which it is convenient to separate from the *Anoplura* (or true Lice) on account of the structure of the mouth, which is mandibulate and also carries palpi. On account of the absence of metamorphoses, some place them (with the *Anoplura*) as outside the pale of the *Insecta*, but they may be regarded as degraded *Pseudo-Neuroptera*. They for the most part live on the feathers of birds (each bird having its particular parasites), but a few also on mammals.

What may be termed **Orthoptera genuina** consist of groups for the most part very sharply defined.

The *Blattidæ* (or Cockroaches) form the order *Dictyoptera* of Leach. These are insects of flattened form, with four horizontal wings (or apterous), of which the anterior pair are considerably coriaceous, but with distinct neuration; the head small; tarsi five-jointed. The eggs are not laid separately, but are contained in a common capsule which is carried about by the female at the extremity of her abdomen. There are many genera and species, of which latter the abundant *Periplaneta orientalis* is the most familiar.

Forficulidæ (or Earwigs) form the order *Euplexoptera* of Westwood and the group *Dermatoptera* of Burmeister. Externally they much resemble *Coleoptera* of the family *Staphylinidæ* in form (but with pincer-like appendages at the extremity of the abdomen), the anterior wings being abbreviated and coriaceous, separated by a suture, and concealing the ample but folded posterior wings (but some forms are apterous); the tarsi three-jointed. The eggs are deposited in cavities in the earth, and are guarded (at any rate in some) by the mother.

Mantidæ are mostly large elongate insects with strongly developed raptorial anterior legs (hence the insects are carnivorous). The prothorax very long; tarsi five-jointed; wings often ample or frequently wanting; all reticulate, but the anterior pair slightly more coriaceous. The earlier states greatly resemble the perfect insect without wings. The eggs are contained in a kind of case formed of a secretion voided with them, in which they are arranged in rows, the whole mass being attached to twigs, etc.

Phasmidæ (Spectres, or Walking-Sticks) have considerable external resemblance to the former, but the anterior legs are not raptorial, and the insects are phytophagous. The wings (when present) are usually much shorter than the abdomen. Most of the species mimic (as do those of the last family) leaves or twigs, often to such a degree that it is hard to imagine one is regarding an insect.

Gryllidæ form the first of a division termed *Saltatoria* (as opposed to *Cursoria* or *Gressoria*), from the structure of the hind legs fitting them for jumping. The antennæ are long and setaceous; tarsi three-jointed; anterior wings lying horizontally over the folded posterior. The males mostly produce sound by a special structure at the base of each anterior wing acting on the posterior. This family is made up of materials presenting considerable diversity, but may be grouped roughly in two, according as the anterior legs are formed for digging (Mole-Crickets) or for running (Crickets).

Locustidæ have the antennæ very long and slender; the tarsi four-jointed; the anterior wings longitudinally deflexed. The female ordinarily has a broad curved ovipositor suitable for forming grooves in bark, or earth, in which the eggs are deposited. They are mostly phytophagous, but in some cases carnivorous also. The males are usually very noisy,—with special sound-producing organs at the base of the anterior wing.

Acrydiidæ differ from the last chiefly in the antennæ, which are shorter and thick, and in the three-jointed tarsi. The female has no produced ovipositor. They are phytophagous, and the eggs are mostly laid in earthen tubes. This family includes (according to modern classification) the true Locusts, notwithstanding the application of the term to the last-mentioned. Sound is produced by friction of the hind thighs against the nervures of the anterior wings.

The *Orthoptera* have here been treated in a somewhat more detailed manner than other orders, on account of the bearing of the materials on the classification of insects in general, and the sharply differentiated nature of these materials in particular.

HEMIPTERA.—This order consists of insects of very varying structure. Primarily there are two great divisions, known as *Heteroptera* and *Homoptera*, by some considered distinct orders. The points in which they agree consist especially in an imperfect metamorphosis, and the structure of the mouth, which latter is of a very simple nature, consisting of an elongated articulate tube formed by an extension of the labium into a suctorial organ, concealed in which are bristle-like mandibles and maxillæ, and probably rudiments of maxillary palpi. The tarsi have from one to three joints.

In the **Heteroptera** (or true Bugs) the anterior wings are horizontal, and composed of two distinct parts, the basal portion (or corium) being coriaceous, and the apical portion (or membrane, often undeveloped) being membranous with distinct longitudinal neuration, which latter is only faintly indicated in the coriaceous portion. In repose the membranous portion of one wing overlaps that on the other. The posterior wings are concealed under the anterior, folded, membranous, and with only few nervures. Apterous forms are not uncommon, and sometimes the posterior wings are wanting. This division is again divided into two, *Gymnocerata* and *Cryptocerata*, in the former of which the antennæ are composed of few elongate slender joints, while in the latter the joints are still fewer, short and thick, and ordinarily concealed under the head. Modern writers have erected a multitude of small subdivisions which cannot be enumerated here. The *Gymnocerata* are broadly divided into the following families, viz., *Scutelleridæ*, *Pentatomidæ*, *Coreidæ*, *Berytidæ*, *Lygæidæ*, *Capsidæ*, *Tingididæ*, *Reduviidæ*, *Emesidæ*, and *Saldidæ*, founded on different points in the structure of the antennæ, rostrum, scutellum of mesothorax, tarsi, etc. They are terrestrial, and suck the juices of plants or animals. The entire family *Reduviidæ* are probably blood-suckers, and members of other families as above given are notorious for a similar habit, amongst which may be particularly noticed the genus *Acanthia* (including the Bed Bug); but the greater part are plant bugs. Most of them are remarkable for emitting a peculiar and often disgusting odor. The *Cryptocerata* are entirely water bugs, often of extraordinary form, and sometimes gigantic in size. They include the families *Hydrometridæ*, *Gerridæ*, *Galgulidæ*, *Nepidæ*, and

Notonectidæ. They prey upon animals. One genus (*Halobates*) is remarkable for its pelagic habits, being found on the surface of the ocean very far from land. Many others, such as *Notonecta* (Water Boatmen or Toe-Biters), *Nepa*, *Ranatra*, etc., are very familiar insects.

The **Homoptera** have the wings for the most part deflexed, and the anterior pair not separated into two parts. Often all the wings are membranous, with strong nervures; in others the anterior pair is coriaceous. The division regarded as a whole is very polymorphic. The true *Homoptera* have three-jointed tarsi. They may be divided into *Cicadidæ* (remarkable for the sound-producing organs at the base of the abdomen of the male), *Fulgoridæ* (known as Lantern-Flies, but now known to produce no light; having the head greatly prolonged in front), *Lystridæ*, *Cixiidæ* (comprising many little plant-hoppers), *Issidæ*, *Derbidæ*, *Flatidæ*, *Tettigometridæ*, *Membracidæ* (often of most extraordinary forms), *Cercopidæ* (included in which is the Cuckoo-Spit Insect), *Ledridæ*, and *Jassidæ*,—all vegetable feeders. The more aberrant *Homoptera* include well-marked groups. The *Psyllidæ* are small plant-sucking saltatorial insects with four membranous wings which lie longitudinally deflexed in repose, and with very narrow prothorax, and eight- to ten-jointed antennæ; they often occasion much damage; the larvæ are frequently covered with a cottony secretion. The *Aphidæ* are the familiar Plant-Lice, the winged forms of which have those organs membranous, and often extended in repose. The antennæ are five- to seven-jointed. The diversity in form and habits is enormous, and, as is well known, there are winged and apterous forms in the same species, and parthenogenetic generation of the most extraordinary nature; and the same species may be both oviparous and viviparous. Most of them void a sweet secretion from abdominal tubes, known as honey-dew, for which they are "milked" by ants. The destruction they occasion to plants is very great; as a now too familiar instance of this, the *Phylloxera vastatrix* of the grape-vine may be cited. *Coccidæ* (or Scale Insects) have the male two-winged, the female apterous, and living all her life as a fixed "scale" on plants, the organs being of the most rudimentary nature; the eggs lying under the scale in great numbers; the tarsi with only one joint; parthenogenesis occurs also in this group; the male in its earlier stages lives under a special scale. The Cochineal Insect is one of the best known in this group. The little family *Aleurodidæ* consists of minute insects covered with a white waxy secretion. They have four almost nerveless wings in both sexes, two-jointed tarsi, the abdomen without secreting tubes, and do not live under scales.

In the *Hemiptera* it is now the fashion to include the **Anoplura**, or true Lice (some also place here the *Mallophaga*, or Bird-Lice), a degraded form of this order, without metamorphosis. Here it is preferred to let them rest in this article, even although some writers do not consider them true insects. The mouth parts certainly have indications of a rostrum, and there are no palpi, and, but for the absence of metamorphosis, there would be little difficulty in fixing the position here as without doubt. All, as is well known, are epizoic parasites on man and other *Mammalia*, each species being confined to a special host, while attempts have been made to prove that the Head-Louse (*Pediculus capitis*) varies according to the races of men to which it is attached. Perhaps the Crab-Louse (*Phthirius pubis*) is regarded with greater disgust than is bestowed upon any other living creature.

COLLEMBOLA and THYSANURA.—In the introductory notes to this article (p. 142) it is stated that "although it is not difficult to define an insect, speaking broadly, there are certain small groups that do not satisfactorily fall into the class as limited by strongly-defined lines of demarcation." The writer there had especially in view those lice known as *Mallophaga* and *Anoplura*, and the two groups indicated in the heading of this section, groups in which metamorphosis, the key of his ideas as to classification, and embodying an essential requisite in an insect according to common acceptance, is wanting. In the time of Linnæus, when we were only outside the threshold of knowledge, it may have been sufficient (and perhaps prudent) to include these groups in an order *Aptera*. But accumulation of knowledge soon dispersed that incongruous order. Such of its elements as could with justice be considered insects have been distributed amongst the various orders. We have not hesitated here to regard the *Mallophaga* as degraded *Pseudo-Neuroptera*, nor the *Anoplura* as equally degraded *Hemiptera*, notwithstanding that some veterans in entomological science may still dispute their position as true insects. There is a breaking-point to elasticity even in ideas of classification, and with regard to the *Collembola* and *Thysanura* we gladly avail ourselves of the assertion of Lubbock to the effect that they are scarcely within the pale of the true *Insecta*, notwithstanding the efforts made to locate them in that convenient refuge for the destitute, the *Pseudo-Neuroptera*. It is certain that the writers in the present work on other classes of *Arthropoda* will not accept them, and it becomes necessary that they should not be forgotten. If insects at all, they have in the process of evolution lost the chief attributes of insects, or have never acquired them. Generally both groups are accepted as *Thysanura*, or as forming two families—*Poduridæ* (= *Collembola*) and *Lepismatidæ* (= *Thysanura*).

In the **Collembola** the antennæ are short, thick, and few-jointed; the eyes are composed of groups of simple "eye-spots" (much as in the larvæ of true insects) varying in number; the mouth organs mandibulate, subject to modifications of a haustellate nature; the palpi quite rudimentary; the abdomen consisting of six segments, and ordinarily provided beneath with a saltatory apparatus (which may, however, be rudimentary); no caudal setæ. The body is often clothed with prismatic scales, not unlike those of *Lepidoptera*. Ordinarily they are minute animals, living in damp places, and sometimes found gregariously. An elongate form is the most general, but *Smynthurus* and *Papirius* are short and obese. Lubbock recognizes six families.

The true **Thysanura** are elongate creatures, not unlike the larvæ of *Ephemeridæ* in form. The antennæ are long, slender, and multi-articulate; the eyes large, compound, and contiguous (or absent); the mouth mandibulate; the palpi well developed; the abdomen consisting of ten segments, with long caudal appendages. Lubbock forms three families. In some of the genera the scales form beautiful microscopic objects; in others they are replaced by hairs. *Lepisma saccharina*—sometimes termed the "Silver Fish"—is a familiar example of *Thysanura*. The genus *Campodea* is especially interesting as being considered by some as the representative of the primitive form of insect, whence all others have been evolved.

Bibliography.—Bibliothecæ and Annual Records:—H. A. Hagen, *Bibliotheca Entomologica*, 2 vols., Leipsic, 1862-3, notices all that has been written on the subject up to date; "Berichte über die wissenschaftlichen Leistungen im Gebiete der Entomologie," in Wiegmann's *Archiv*, 1835–1880; *Zoological Record*, London, 1865–1881. Girard, *Les Métamorphoses des Insectes*, Paris, 1874, and the general handbooks noticed above. Classification and Special Entomology:—An analysis of the various schemes proposed by the principal systematists is to be found in the works noticed under the heading "General Handbooks," up to the date of

their publication; those by Kirby and Spence, Westwood, Burmeister, Packard, and Gerstäcker are most recommended. For a much condensed account, F. P. Pascoe's *Zoological Classification*, 2d edition, 1880, will be found useful. For information on special orders or groups of insects, reference should be made to the "Register" at the end of the second volume of Hagen's *Bibliotheca Entomologica*, or to the German *Berichte* and the English *Zoological Record*. (R. M'L.)

INSPIRATION is the Latin equivalent of *θεοπνευστία*, and is used to express the fact that holy men of old spake as they were moved by the Spirit of God. The idea is not exclusively Christian or Jewish; pagans have had their inspired speakers and writers and their ideas of inspiration, and these earlier pagan notions have had their effect on some of the forms which the Christian doctrine has assumed.

The classical languages contain many words and phrases expressive of this idea, *e. g.*, *θεοφόροι* (Æsch., *Agam.* 1150), *θεοπνεύστοι* (Plut., ii. 904 *sq.*; *cf.* 2 Tim. iii. 15), *θεοπρόποι* (*Iliad and Odyssey*, *passim*), *ἔνθεοι* (Plato, *Phædr.* 244), *μαινόμενοι*, *divino numine afflati*, *divino spiritu instincti*, *inspirati*, *furentes*. Artistic powers and poetic talents, gifts of prediction, the warmth of love, and the battle frenzy were all ascribed to the power of the god possessing the man inspired. And these words were taken over into Christian theological writing, and used to describe what Jewish and Christian divines have called inspiration. This transference of terms, which was unavoidable, produced, however, a certain confusion of thought; for pagans and Christians meant by inspiration two different things. When a pagan described inspiration, he did so by stating the marks of the state into which the inspired person fell when the fit seized him; a Christian theologian on the other hand was chiefly concerned with the result of inspiration. What the inspired person said or did or commanded was of less moment to the pagan philosopher than the fact that he was possessed, that he was passive in the hands of the inspiring deity, that he was no longer himself but the god who for the moment dwelt in him and used him as he might an inanimate instrument. But in Christian theology inspiration always has to do with the belief that God has "wholly committed to writing" His revelation, and the psychological character of the state of inspiration is of small account compared with the fact that inspiration, whatever it may be, has for its result that God's revelation has so been committed to writing that men have it permanently, fully, and in an infallibly trustworthy way. In pagan literature *θεόπνευστος* is applied primarily to men who have been possessed; in Biblical and ecclesiastical language its primary use is to denote the writings which are the result of inspiration. The words in the mouth of a pagan mean primarily the psychological state, in the mouth of a Christian they mean the characteristics of a book or set of writings.

The doctrine of inspiration in Christian theology contains very little reference to the psychological state of the persons inspired, and when it does enter into such details we may generally trace their presence back to the influence of pagan ideas or words; it has to do with the characteristics of the writings which have been inspired. In short, the problem of inspiration in Christian theology very much comes to this:—In the Bible we have God's revelation wholly committed to writing; what are we to infer from this about the Bible? And the varying answers given to this question form the history of the doctrine. Theology distinguishes between revelation, inspiration, and the canon of Scripture. Revelation is the objective approach of God to man, God entering into human life and history for man's salvation; Scripture is the record of this revelation, and inspiration provides that the record is complete and trustworthy; while the canon of Scripture gives the list of inspired writings.

It does not belong to an historical article like this to describe more minutely the doctrine of inspiration or its basis in Scripture and in the Christian experience; all that can be done here is to state as concisely as possible various answers made to the main problem involved.

1. *Jewish Theologians.*—Our knowledge of the opinions of ancient Jewish thinkers about inspiration comes chiefly from the Apocrypha, from Josephus, and from Philo Judæus. The writers of the Apocrypha do not give us any theory or doctrine of inspiration, but it may be easily gathered from what they say that they regarded the Scriptures of the Old Testament as the word of God, and therefore worthy of all reverence. It is in 1 Macc. xii. 9 that the expression *τὰ βιβλία τὰ ἁγία* is first used of Old Testament books; and it is evident that the Pentateuch or the books of the law were held in special reverence, but beyond this we do not find a doctrine of inspiration. Nor does Josephus formally state or discuss the dogma in his writings, but his language shows that he and his contemporaries believed that the Old Testament Scriptures were the word of God. The Old Testament he calls prophecy, and he declares that down to the time of Artaxerxes there was a regular succession of prophets which since then has ceased (*Contra Apion.*, lib. i. c. 8). It is Philo who first seeks to give a theory of inspiration, and he does so by bringing the reflections of Plato upon the pagan inspiration or *μανία* to explain the Jewish doctrine. Following Plato, Philo says that inspiration is a kind of "ecstacy," and he seems to imply that the degree of inspiration is greater in proportion to the unconsciousness or at least to the passivity of the man inspired. The prophet, he says, does not speak any words of his own, he is only the instrument of God, who inspires and who speaks through him (*De Specialibus Legibus*, § 8); but he says that there are degrees of inspiration, and that all portions of Scripture are not equally inspired, or at least have not the same depth of inspiration. Moses has the first place in the scale of inspired writers; he is *ἀρχιπροφήτης*, while others are *Μωυσέως*, *ἑταῖροι*, *μαθηταί*, *θιασῶται*, *φοιτηταί*, *γνώριμοι*; but this idea of degrees of inspiration, a conception borrowed from Plato, does not seem to prevent Philo from thinking that the very words of the Old Testament were all inspired of God (*Vit. Mos.*, 2, § 7). It was also a common opinion among the Rabbins of the early Middle Ages that the inspiration of the Old Testament required that, not merely the thoughts and words of Scripture, but even the vowel points and accents were themselves of divine origin; but this idea seems to have been compatible with the theory that there were three degrees of inspiration, the highest being the inspiration of the Pentateuch and the lowest that of the Hagiographa.

2. *The Church Fathers.*—The early Christian church seems to have simply taken over the Jewish views about the inspiration of the Old Testament; and, when the New Testament canon was complete, they transferred the same characteristics to the New Testament writings also. It is evident that the early fathers of the church wished to teach that the complete knowledge of the salvation of God revealed in Christ was to be found in the Holy Scriptures because they were the book of God, but it is difficult to gather any consistent doctrine of inspiration from their writings, and when they do speak of inspiration it seems as if they were thinking more of the psychological process going on in the mind of the inspired man than of the result in the character of an inspired book. It was perhaps difficult for men educated in the principles of heathen philosophy to avoid applying their early belief about the pagan *μανία* to explain or define the Christian idea of inspiration. At all events we find the doctrine of inspiration described under such metaphors as the Pla.

tonists were accustomed to use: the inspired writer was the lyre, and the Holy Spirit the plectrum; the writer was the vase, and the Spirit filled it; and Montanus could appeal to the almost unanimous idea of the church that prophecy implied both passivity and ecstacy. This view of inspiration was strengthened by the Apologists, who were accustomed to plead for the credibility of the inspiration of the Scriptures by appealing to the oracle of Dodona, to the supernatural character of the Sibylline books, and to the universally accepted fact of *μανία*. Origen, who so frequently anticipates later criticism, was one of the earliest theologians who really attempted to construct a theory of inspiration. He said that the Scriptures contain the plenitude of the Holy Spirit, and that there was nothing in the law nor in the gospel which had not come down to us from the fulness of the Divine Majesty. Inspiration, he declared, preserved the writers from any faults of memory, and made it impossible to say that there was anything superfluous in Scripture. He got over difficulties either by allegorical interpretations, or by declaring that God, like a teacher, accommodates Himself to the degree of civilization in various ages. But the church of the early centuries was hindered from considering the doctrine of inspiration on all its sides by two influences. Throughout the early church the common opinion prevailed that the Scriptures were of great practical importance and promoted the edification of believers. But the church scarcely set itself seriously to ask how the Scriptures edified believers and in what their practical importance consisted; yet these questions bore upon a right understanding of their inspiration. It seems evident, however, that ever since the early conflicts with Gnosticism the church was tempted to look upon Scripture as primarily a means of information, and not so much a means of grace. The Scriptures edified because they instructed, and were of importance because they gave information not otherwise attainable; and so inspiration, whatever else it was, came to be regarded as the means whereby that information was kept correct. It had been always held that the divine agent in inspiration was the Holy Spirit, but the precise function of the Spirit was not clearly defined. The early theologians, when discussing the inspiration of the apostles, forgot the writing in describing the writers, and enlarged on the powers communicated to them by the Spirit of God to guide the church, to work miracles, and to foretell the future. The promise of the Spirit, however, was not confined to the apostles; all believers were to share in it. Justin Martyr speaks of the miraculous powers of the apostles, and of the spiritual gifts of all Christians, as if the two were the same; and Tertullian, while he does draw a distinction between the inspiration of the apostles and that common to all believers, declares that the difference is one of degree, the inspiration of believers being only partial inspiration. Out of these conflicting tendencies there emerged in due time a double doctrine of inspiration. The Scriptures were inspired to teach infallible truth, and believers were inspired also with something of the same kind of inspiration to interpret this infallible truth. For though it was not distinctly stated, yet still there were intimations of what was to come. Whenever the Bible is looked on as altogether or even chiefly a means of knowledge, and not as a means of grace also, the intellectual aspect overcomes or drives into the background the conception of the Bible as a grace-giving power, and there is need of infallible interpretation as well as of infallible delivery of the propositions which convey the knowledge. In short, the doctrine was in such a state that at any moment it might crystallize into a theory that would practically deny to the ordinary believer the saving use of Scripture as a means of grace. The occasion was furnished by Montanism, which revived within the Christian church the old pagan idea of *μανία*, and applied it not to the original Scriptures but to the infallible interpretation of Scripture. The Montanist prophets claimed to be possessed of the Spirit as the Old Testament prophets had been, but this inspiration they used, not so much to give additional Scriptures, as to give authoritative exposition of the Scriptures already delivered to the church. Theologians rejected the Montanist *μανία*, denied that passivity and ecstacy were marks of inspiration, but none the less did the real essence of Montanist prophecy find its way into the church, for the result was a double doctrine of inspiration,—the inspiration of Scripture, which insured that the knowledge they communicated was correct, and the official inspiration of the church, which insured that the knowledge infallibly communicated was infallibly understood. This brings us to the scholastic period.

3. The *Schoolmen* accepted the doctrine of inspiration as it came to them from the fathers, and methodized it. They held that the Bible, which was the word of God and therefore inspired, was the source of doctrinal truth; and so this inspiration of the Bible came out in the fact that the doctrinal truths contained in it were infallibly true. The Schoolmen also recognized that a revelation which is primarily doctrinal, and that only, requires infallibility in interpretation as well as infallibility in delivery; and so the inspiration of the church was as important as the infallibility of Scripture. As time went on the infallible interpretations were collected, and side by side with an infallible Scripture was the infallible tradition or the official interpretation of Scripture. The logical Schoolmen, however, perceived, what was not so distinct to the fathers of the church, who were accustomed to think in pictures rather than in propositions, that if the Bible was altogether a communication of doctrinal truth there was much in the Scriptures which had not at first sight that appearance. The long histories, the tables of genealogy, did not contain doctrinal statements, or give rules of holy living. Were these portions inspired? The question does not require to be raised if we believe that inspiration implies simply that God has fully committed his revelation to writing, and that revelation is above all things God entering into human life and history for the salvation of his people; for then the whole course of the history, with all the facts as well as the doctrines, contains the revelation. But if we take revelation to be only the delivery of doctrines, the question arises and disturbs our theory of inspiration. The fathers solved every difficulty here by appealing to allegorical interpretation, for allegory will turn the driest statistical details into a moral or doctrinal code; but the Schoolmen were too dryly logical to be quite content with this explanation. They accepted the allegorical senses of Scripture, but many of them held, like Thomas Aquinas (*Summa* ii. 2, qu. 1, art. 6; qu. 2, art. 2), that there were two kinds of inspiration in Scripture, the *direct*, which is to be found where doctrinal and moral truths are directly taught, and the *indirect*, which appears in historical passages, whence the doctrinal and moral can only be indirectly evolved by the use of allegorical interpretation. Many different opinions, however, were held about the details of the doctrine. Gregory the Great called the writers of Scripture the *calami* of the Holy Spirit, to denote how entirely the Bible was the work of God; while Agobard of Lyons asserted that the inspiration of Scripture did not exclude the presence of grammatical errors. Thomas Aquinas was content to say simply that God is the author of Scripture (*Summa* 1, qu. 1, art. 10); but elsewhere he discusses at some length the psychological aspects of the inspiration of the prophets.

4. The *Reformers* placed the authority of Scripture above the decrees of popes and councils, above the opinions of the fathers, above the whole digest of official interpretations of Scripture which made tradition. They regarded Scripture as the judge in all controversies in matters of faith and doctrine, and as the source whence came every article of belief; but besides this they held that Scripture was a means of

grace, a principle of salvation, a means of awakening the new life in the hearts of God's people. This was the real gist of the Reformation doctrine of Scripture; this was the main part in the contribution which the Reformers made to the doctrine of the word of God. The fathers had spoken of the practical importance of Scripture and its power for edification, but they had placed these qualities in a secondary position, and in the scholastic period Scripture came to be regarded as little more than a quarry for doctrines. The Reformers insisted that all doctrines must come from Scripture; they held that the Scripture was the book of the all-wise God, and was therefore the touchstone in matters of religious controversy, but they also held that above all the Scripture was the sword of the Spirit, and that its main use was to pierce the heart and conscience. According to the Reformers, the revelation of God was fully committed to writing in the Scriptures, and the inspiration of Scripture lay in this fact; but they held that the special nature of inspiration must be derived from the purpose of God in this matter. God fully committed His revelation to writing, they argued, not merely to impart new knowledge to men, but also and principally to awaken His people to a new life; and this purpose must appear in the statement of the doctrine of inspiration. Thus the Reformation doctrine of inspiration, while capable of statement in terms somewhat similar, was really different from the patristic and mediæval theories, and it became more closely allied with the written Scriptures, and paid less attention to the writers. It taught that Scripture as a whole, and the parts of Scripture looked at as parts of the one whole, were designed to be a means of grace, to awaken a new life in God's people, through the work of the Spirit, and thus the doctrine of inspiration was at once brought into connection with and yet clearly separated from the spiritual illumination shared by all believers. It is allied because both the inspiration of Scripture and the enlightening work of the Spirit in the hearts of believers are parts of the plan of God whereby by His means of grace through the work of the Spirit He gathers believers into His kingdom; it is quite distinct, for by it God wholly commits his revelation to writing, and so makes the Scripture able to appeal with the very power of God to the hearts and consciences of men. In this way the doctrine of inspiration was advanced a stage beyond what it had before reached, and indeed was raised to a higher platform. It was now seen that inspiration secured that the Scriptures should be instinct with God's power for salvation, as well as full of the knowledge which God has pleased to communicate to man. And thus in the hands of Luther, Calvin, and Zwingli the doctrine of inspiration had for its correlative the doctrine of the *Testimonium Spiritus Sancti*; the two doctrines supported and explained each other. The second raised the first out of the region of mechanical dictation, the first prevented the second degenerating into a mystical enthusiasm. The Reformers were content to leave the doctrine of inspiration without much further definition, but they took the full advantage of the spiritual form of the doctrine to use great freedom with the letter of Scripture. Their successors acted otherwise.

5. The *Protestant Scholastic* for the most part treated the Reformers' doctrine of inspiration very much in the same way as the Schoolmen had treated the doctrine of the fathers. They did not deny the spiritual side of the doctrine; they maintained that Scripture was a means of grace, a power of God to salvation; but they did not bring this side forward much in their discussions about inspiration. They dwelt on the fact that inspiration secured accuracy, rather than on the fact that it brought with it spiritual power. They asked, When Scripture is the word of the all-wise God, what does this imply? And the answers were various. Gerhard held that it implied that the writers were the "pens," the "hands," the "amanuenses," of the Holy Ghost. We may with propriety, he says, call the prophets and the apostles "amanuenses Dei, Christi, manus et Spiritus sive tabelliones sive notarios." Calovius and Quenstedt say the same. Quenstedt holds that everything in Scripture comes from the infallible divine assistance and direction, from a special suggestion and dictation of the Holy Spirit; and he says that because Scripture is inspired it is of infallible truth and free from every error; canonical Scripture contains no lie, no falsehood, not the very slightest error either in fact or in word; whatever things it relates, all and every one of them, are of the very highest truth, whether they be ethical or historical, chronological, topographical, or verbal; there is no ignorance, no want of knowledge, no forgetfulness, no lapse of memory in Scripture. The framers of the *Formula Consensus Helvetica* went further, and declared that the Old Testament was "tum quoad consonas, tum quoad vocalia, sive puncta ipsa, sive punctorum saltem potestatem, et tum quoad res, tum quoad verba *θεόπνευστος*." On the other hand, Cappellus, led by his investigations into the antiquity of the Hebrew points, maintained that the inspiration of Scripture did not necessarily demand perfect accuracy in details; and he declared that such accuracy not only did not exist in such editions as we have now, but never did exist, for manuscripts show discrepancies which cannot be explained on the theory of wilful or involuntary mistakes of copyists.

The Socinians and certain Arminians, such as Episcopius, who started with the idea that the Bible is simply a communication of knowledge, and so revived the mediæval idea, also resuscitated the scholastic doctrine of partial inspiration. They did not admit the allegorical method of interpretation, and were therefore compelled to reject the "indirect inspiration" of Thomas Aquinas; but they held that inspiration was only required to communicate knowledge which the writer could not otherwise obtain, and they usually asserted that only the doctrinal parts of the Bible were inspired while the historical were not. Calixtus in the Lutheran Church held a somewhat similar opinion.

6. In more recent times the doctrine of inspiration has assumed various forms, many of which have but slight connection with either the Reformation or the mediæval theories. All admit that the inspiration of Scripture implies that the revelation of God has been committed to writing. Those who hold naturalistic views of revelation reduce inspiration to a peculiar aptitude for and sympathy with religious and moral truth. Others, although believing in the supernatural character of revelation, hold that there is no warrant to suppose anything specially supernatural about the committal of the revelation to writing, and believe that God left His revelation to be recorded in the natural course of providence by men who had perhaps a larger share than their fellows of the spiritual enlightenment common to all believers. Others again have revived the old Thomist doctrine that parts of the Bible are inspired and that parts are not. To meet such theories, orthodox theologians have invented the terms plenary inspiration and verbal inspiration, but the phrases are neither very exact nor very enlightening. Meanwhile it is interesting to observe that a number of modern theologians, among whom may be named the late Adolphe Monod of Paris, have sought to revive the old simple Reformation form of the doctrine divested of its 17th century subtilties.

(T. M. L.)

INSTERBURG (16,303), the chief town of a circle in government district of Gumbinnen, East Prussia, is situated at the point where the Angerap and Inster join to form the Pregel, about 55 miles east of Königsberg. It is the seat of an appeal and other courts, and of a reformatory for the district, and has a chamber of commerce, a hospital, a gymnasium, a real-school of the first class, and several other schools. Insterburg is an active manufacturing town, and, besides flax-spinning and iron-founding, carries on the manufacture of machinery, shoes, cement, leather, and furs, along with a considerable trade in cereals, vegetables, flax, linseed, and wood. Close to the town is a large stud-farm, and about 2 miles off is the old castle of Georgenburg. Including the garrison, the population in 1875 was 16,303.

Insterburg was founded in the 14th century as a castle and commandery of the knights of the Teutonic order. The commandery was removed in 1525, but the village which had sprung up round the castle received town privileges in 1583 from the margrave of Brandenburg. During the next century it made rapid advances in prosperity, owing to the settlement in it of several Scotch trading families. In 1679 it was besieged by the Swedes, in 1690 it suffered severely from a fire, and in 1710–11 from a pestilence.

INSTINCT is a term which does not admit of rigid definition, because, as ordinarily used, the meaning of the term is not rigidly fixed. But for the purposes of scientific exposition from a biological point of view the nearest approach we can make to such a definition is perhaps the following:—Instinct is a generic term comprising all those faculties of mind which lead to the conscious performance of actions that are adaptive in character, but pursued without necessary knowledge of the relation between the means employed and the ends attained. We must, however, remember that instinctive actions are very commonly tempered with what Pierre Huber calls "a little dose of judgment or reason." But although reason may thus in varying degrees be blended with instinct, the distinction between the two is sufficiently precise; for reason, in whatever degree present, only acts upon a definite and often laboriously acquired knowledge of the relation between means and ends. Moreover, adjustive actions due to instinct are similarly performed by all individuals of a species under the stimulus supplied by the same appropriate circumstances, whereas adjustive actions due to reason are variously performed by different individuals. Lastly, instinctive actions are only performed under particular circumstances which have been frequently experienced during the life history of the species, whereas rational actions are performed under varied circumstances, and serve to meet novel exigencies which may never before have occurred even in the life history of the individual.

Origin of instincts.

All instincts probably arose in one or other of two ways. (1) By the effects of habit in successive generations, mental activities which were originally intelligent become, as it were, stereotyped into permanent instincts. Just as in the life-time of the individual adaptive actions which were originally intelligent may by frequent repetition become automatic, so in the life-time of the species actions originally intelligent may, by frequent repetition and heredity, so write their effects on the nervous system that the latter is prepared, even before individual experience, to perform adaptive actions mechanically which in previous generations were performed intelligently. This mode of origin of instincts has been appropriately called the "lapsing of intelligence." (2) The other mode of origin consists in natural selection, or survival of the fittest, continuously preserving actions which, although never intelligent, yet happen to have been of benefit to the animals which first chanced to perform them. Thus, for instance, take the instinct of incubation. It is quite impossible that any animal can ever have kept its eggs warm with the intelligent purpose of hatching out their contents, so we can only suppose that the incubating instinct began by warm-blooded animals showing that kind of attention to their eggs which we find to be frequently shown by cold-blooded animals. Thus crabs and spiders carry about their eggs for the purpose of protecting them; and if, as animals gradually became warm-blooded, some species for this or for any other purpose adopted a similar habit, the imparting of heat would have become incidental to the carrying about of the eggs. Consequently, as the imparting of heat promoted the process of hatching, those individuals which most constantly cuddled or brooded over their eggs would, other things equal, have been most successful in rearing progeny; and so the incubating instinct would be developed without there having been any intelligence in the matter.

That many instincts must have been developed in this way is rendered evident by the following considerations: (1) Many instinctive actions are performed by animals too low in the scale to admit of our supposing that the adjustments which are now instinctive can ever have been intelligent. (2) Among the higher animals instinctive actions are performed at an age before intelligence, or power of learning by individual experience, has begun to assert itself. (3) Considering the great importance of instincts to species, we are prepared to expect that they must be in large part subject to the influence of natural selection. As Mr. Darwin observes, "it will be universally admitted that instincts are as important as corporeal structures for the welfare of each species under its present conditions of life. Under changed conditions of life it is at least possible that slight modifications of instinct might be profitable to a species; and if it can be shown that instincts do vary ever so little, then I can see no difficulty in natural selection preserving and continually accumulating variations of instinct to any extent that was profitable. It is thus, I believe, that all the most complex and wonderful instincts have originated."

But here it is of importance to note that there is no reason why instincts should be restricted to one or other of these two modes of origin. On the contrary, there seems to be every reason to suppose that many instincts may have had, as it were, a double root—intelligent adjustment and natural selection blending their influences to a joint production. For example, the grouse of North America display the curious instinct of burrowing a tunnel just below the surface of the snow. In the end of this tunnel they sleep securely; for, when any four-footed enemy approaches the mouth of the tunnel, the bird, in order to escape, has only to fly up through the thin covering of snow. Now in this case the grouse probably began to burrow for the sake of protection, or concealment, or both, and if so, thus far the burrowing was probably an act of intelligence. But the longer the tunnel the better would it have served the purposes of escape, and therefore natural selection would almost certainly have tended to preserve the birds which made the longest tunnels, until the utmost benefit that length of tunnel could give had been attained. And similarly the origin of many other instincts may be satisfactorily explained by thus supposing the combined operation of two causes—intelligent adjustment and natural selection—where there is a difficulty in explaining their origin as due to either cause alone. And if even in fully formed instincts we often find "a little dose of judgment or reason," we can have no cause to doubt that in the formation of instincts by natural selection such small admixtures of judgment or reason may often greatly assist the process, while, conversely, it is even more evident that an instinct which is developing from the habitual performance of an intelligent action might be greatly assisted by natural selection favoring the individuals which most frequently or most promptly performed that action.

Variability.

It is necessary to the above interpretation of the origin of instincts that the latter should not be immutably fixed. A few words may therefore be added to show that the view commonly entertained as to the unalterable character of instincts is erroneous. As a matter of fact, instincts are eminently variable, and therefore admit of being modified as modifying circumstances may require; their variability gives them plasticity whereby they may be moulded always to fit an environment, however continuously the latter may be subject to gradual change.

For the sake of brevity we may confine our attention to a single instinct, and for the sake of procuring a good test we may again take as our example the instinct of incubation. This affords a good test because it must be regarded, not merely as one of the most important, but also as one of the oldest of instincts, and therefore one which for both these reasons we should deem least likely to exhibit variability. Yet we find it to exhibit variability in every imaginable direction. Thus the complicated effects of domestication and artificial selection on some of our breeds of poultry appear to have almost completely destroyed this instinct, while in other breeds it remains intact, if indeed it has not even been intensified. Among the latter breeds experiment shows that the natural period of incubation may be indefinitely prolonged by substituting "dummies" for eggs, while the following experiment, which we owe to Mr. Spalding, shows "how far the time of sitting may be interfered with in the opposite direction. Two hens," he says, "became broody on the same day, and I set them on dummies. On the third day, I put two chicks a day old to one of these two hens; she pecked at them once or twice, seemed rather fidgety, then took to them, called them to her, and entered on all the cares of a mother. The other hen was similarly tried, but with a very different result; she pecked at the chickens viciously, and both that day and the next stubbornly refused to have anything to do with them." Similarly the period of maternal supervision after the chickens have been hatched admits of being greatly modified, as is proved by some experiments made and published several years ago by the present writer. In one of these experiments there was given to a Brahma hen a pea-fowl's egg to hatch; the hen was an old one, and had previously reared several broods of ordinary chickens. A pea-chicken requires a much longer period of maternal care than does an ordinary chicken, and for the wonderfully long period of eighteen months the old Brahma hen continued to pay unremitting attention to her supposed offspring. Through all this time she never laid any eggs, and eventually the separation seemed to take place from the side of the peacock. In other cases, however, where the conditions of the experiment were exactly parallel, the pea-chickens were abandoned by their Brahma mothers at the time when the latter ordinarily abandon their chickens. But not only will a hen thus take to a brood of birds so unlike her natural chickens as are pea-fowl, and adapt her instincts to their peculiar needs; she may even take to young animals belonging to a different class, and adapt her instincts to their still more peculiar needs. Thus the writer gave to a hen, which for several weeks had been sitting on dummies, three newly-born ferrets; she took to them almost immediately, and remained with them for more than a fortnight, when they were taken away from her. During the whole of this time she had to sit upon the nest, for, of course, the young ferrets were not able to follow her about as young chickens would have done. Two or three times a day she would fly off her nest, calling upon her brood to follow; but, on hearing their cries of distress from cold, she always returned immediately, and sat with patience for six or seven hours more. She only took one day to learn the meaning of these cries, and after that she would always run in an agitated manner to any place where the crying ferrets were concealed. Yet it would not be possible to conceive a greater contrast than that between the shrill piping note of a young chicken and the hoarse growling noise of a young ferret. It is of importance to add that the hen very soon learnt to accommodate herself to the entirely novel mode of feeding that her young ones required; for, although at first she showed much uneasiness when the ferrets were taken from her to be fed, before long she used to cluck when she saw the milk brought, and surveyed the feeding with satisfaction. But she never became accustomed to the attempt of the ferrets at sucking, and to the last used now and then to fly off the nest with a cackle when nipped by the young mammals in their search for the teats.

Hereditary transmission.

Enough then has been said on the variability of instinct to show that there is supplied to natural selection abundant opportunity for the development of new and more highly wrought instincts from previously formed and less elaborated instincts. But in order to show that this opportunity has been utilized it is not enough to show that hereditary instinct may be modified by individual experience; it must also be shown that such a modification when successively repeated through a number of generations itself becomes inherited. Now, although the evidence on this point is necessarily scanty, it is sufficient for the purpose here required. The evidence is scanty because there are only a very few cases in which human observation has, as it were, the opportunity of watching the continuance of effects of recently acquired or altered experiences over a number of generations; but in the few cases in which we have this opportunity we find good evidence that new or changed experience, when continued over a number of generations, is bequeathed to future generations as a legacy of intuitive knowledge, and that any newly acquired adjustive actions may in time be similarly transmitted as instinctive actions which no longer require to be separately learnt by each individual. Perhaps the best instance that can be quoted is that of the many species of birds, and some mammals, which when first found by man on oceanic islands were perfectly tame, but whose descendants now show a dread of man which is, in the most rigorous sense of the word, instinctive.

The only other instances in which we have an opportunity of actually observing the transmission of newly acquired mental habits are those in which such habits have been artificially taught to domesticated animals. It so happens that these instances are very few in number, but it is not too much to say that, in all the cases where such habits have been taught for a long series of generations, some tokens of their hereditary transmission may now be observed. Thus, to quote Mr. Darwin, whose accuracy on such a subject is not likely to be disputed by any one, "it cannot be doubted that young pointers—I have myself seen a striking instance—will sometimes point and even back other dogs the very first time they are taken out; retrieving is certainly in some degree inherited by retrievers; and a tendency to run round instead of at a flock of sheep by shepherd dogs. If we were to behold one kind of wolf when young and without any training, as soon as it scented its prey, stand motionless like a statue, and then slowly crawl forward with a peculiar gait, and another kind of wolf rushing round instead of at a herd of deer, and driving them to a distant point, we should assuredly call these actions instinctive. Domestic instincts, as they may be called, are certainly much less fixed than natural instincts, but they have been acted on by far less rigorous selection, and have been transmitted for an incomparably shorter period, under less fixed conditions."

Now these three habits, or mental attainments, are the only ones that have been systematically taught to any animals for a number of generations, and the fact that they all show a marked tendency to become intuitive may be taken as lending a greater amount of confirmation to the present theory of the origin of instincts than we might on *a priori* grounds be led to expect. The only other facts bearing upon this point are those which are thus tersely rendered by Mr. Darwin. "How strongly these domestic instincts, habits, and dispositions are inherited, and how curiously they become mingled, is well shown when different breeds of dogs are crossed. Thus it is well known that a cross with a bull-dog has affected for many generations the courage and obstinacy of greyhounds, and a cross with a greyhound has given to a whole family of shepherd dogs a tendency to hunt hares. These domestic instincts resemble natural instincts, which in like manner become curiously blended together, and for a long time exhibit traces of the instincts of either parent."

Special difficulties.

The above doctrine as to the nature, origin, and development of instincts serves very satisfactorily to explain nearly all the enormous number of instincts with which we are acquainted. There are, however, several special cases where there is still some difficulty in applying the above doctrine as a full and satisfactory explanation of the observed facts. This article may therefore fitly conclude with a brief enumeration of these cases.

1. The so-called "migratory instinct" is one that is still shrouded in much obscurity. The main difficulty with regard to it is to account for the "sense of direction," whereby the animals are guided to their destinations. Thus, for instance, many migratory birds fly at night, when it would seem impossible that they can be guided on their way by the sight and memory of landmarks. Moreover, it is asserted on good authority that among some species it is the habit for the young brood to fly separately by themselves, or apart from the older birds, and therefore to travel over enormous tracts of land and sea without either guidance or previous experience of the way; such is unquestionably the case with the young of the cuckow. Lastly it is certain that several species fly across immense tracts of ocean, where it is impossible that they can be guided on their way by landmarks. Several theories have been propounded to account for these facts; but, as none of them are satisfactory, we need not here occupy space with their enumeration.

2. Closely allied to, if not identical with, this so-called "sense of direction" as manifested in migration, is the faculty whereby various species of animals which may not be migratory in their habits are enabled to find their way over greater or less distances. This has been called the "homing" faculty, and is chiefly manifested by various species of domesticated mammals. It is very generally believed that it is also manifested by carrier-pigeons; as a matter of fact, however, there is no trustworthy instance on record of one of these birds having found its way back over a tract of country with which it was previously unacquainted. In order that a carrier-pigeon should find its way home, it is necessary first to teach the animal, by flying it at a series of points along the route, the landmarks of the country which it is afterwards to traverse. But, although the "sense of direction" may be a figment as regards the carrier-pigeon, there can be no doubt that it is a fact as regards many species of our domesticated mammals. Thus the evidence is unequivocal with regard at least to dogs, cats, horses, sheep, pigs, and cattle. Judging from hitherto unpublished correspondence received from Australia and South America, there seems to be practically no limit to the distance over which these animals may be able to return; and, what is of more importance, there can be no doubt that these animals, when finding their way home, do not require to traverse the exact routes by which they came; on the contrary, they generally seem to select the shortest or the straightest course, however circuitous the way may have been by which they were taken; or, if their outward journey is over two sides of a triangle, their homeward journey will probably be taken over the third side. The sense by which they are guided therefore cannot be, as has been suggested by more than one eminent naturalist, the sense of smell; and for the same reasons it cannot be either the sense of sight or that of hearing. More plausible is the hypothesis that the faculty consists in an automatic process of "brain registration," every change of direction in the outgoing journey leaving behind it a record in the cerebral nervous system, and therefore in the mind of the animal, so that as a total result the general direction of the starting place is retained in the memory,—just as we are ourselves able in a smaller degree to preserve our general sense of direction when winding through the streets of a town. One great difficulty attaching to this view appears to be that the animals in question are able to find their way home over land even when they have made their outward journey by sea, for it is evident that the difficulties of "brain registration" must in such cases be indefinitely increased, not only by the many meaningless movements of a vessel at sea, but still more by the fact that the changes of direction made by the vessel, being made in long and easy curves, and without muscular effort on the part of the animals, are movements which we can scarcely suppose to be appreciated by the cerebral organization of the animals. On the whole, therefore, with regard to the faculty of "homing," as with regard to the analogous if not identical faculty exhibited in migration, it can only be said that further investigation is required in order to explain that which, in the present state of our knowledge, must properly be regarded as inexplicable.

3. Mr. Darwin has pointed out a serious difficulty lying against his theory of the origin of instincts by natural selection, and one which, as he justly remarks, it is surprising that no one should have hitherto advanced against the well-known doctrine of inherited habit, as taught by Lamarck. The difficulty is that among various species of social insects, such as bees and ants, there occur "neuter" or asexual individuals, which manifest entirely different instincts from the other or sexual individuals, and as the neuters cannot breed it is difficult to understand how their peculiar and distinctive instincts can be formed by natural selection, which, as we have seen, requires for its operation the transmission of mental faculties by heredity. The only possible way in which this difficulty can be met is the way in which it has been met by Mr. Darwin, viz., by supposing "that selection may be applied to the family as to the individual." "Such faith may be placed in the power of selection that a breed of cattle always yielding oxen with extraordinarily long horns could, it is probable, be formed by carefully watching which individual bulls and cows, when matched, produced oxen with the longest horns; and yet no one ox would ever have propagated its kind;" and similarly, of course, with regard to the instincts of neuters. As Mr. Darwin has argued out this difficulty at length, it seems unnecessary to say more with regard to it than that he has shown it to be not so formidable as to exclude his doctrine as fully explanatory of such cases, when we have already accepted his doctrine as explanatory of other cases.

4. There are two or three other special instincts of minor importance the explanation of which is not as yet completely clear. Thus it is not yet ascertained what hereditary influence it is that leads the Norwegian lemming periodically to migrate westwards, with the result that enormous numbers of the species are destroyed by drowning. But there can be little doubt that this influence, whatever it was, was originally of benefit to the species, for it would be a case standing out of all analogy if this instinct should from its first origin have been, as it now appears to be, detrimental. The only other instance that could be pointed to as wearing any such appearance is that which has been alleged, but on very doubtful evidence, with regard to the scorpion committing suicide by stinging itself to death when surrounded by a ring of fire. It may be here incidentally observed that the fact of all the innumerable multitude of animal instincts, with the exception of the two dubious cases just mentioned, being of obvious use to the species which manifest them, may properly be taken as the strongest possible evidence of the theory that ascribes all instincts to the operation of natural selection.

5. Lastly, we have an instinct which is pointed to by Mr. Mivart as one that cannot be explained by the influence of natural selection, or, as he would appear to suggest, by the operation of any other natural cause. This instinct is manifested by a certain wasp-like animal, and consists in this animal stinging spiders in the particular part of the cephalo-thorax which contains the principal nervous centre. The effect of stinging this nervous centre is that of paralyzing the spider without killing it, and the spider in this maimed condition is then stored up with the larvæ of the fly, to serve as their food when they quit the egg. It will be observed that there is here no question as to the utility of the instinct to the species which manifests it, and the difficulty to which Mr. Mivart points consists merely in understanding how the insect was in the first instance led to sting the spiders in precisely the right spot to produce the particular results required. The answer to this single remaining difficulty is that as yet the case has not been sufficiently observed with a view to a possible solution of the difficulty. It seems, for instance, not at all improbable that the striking of the spider's ganglion by the sting of the wasp is, as it were, wholly accidental, being determined only by the circumstance that both the ganglion and the sting are organs which occur in the median line of their respective possessors. Whether or not this is the explanation of the supposed difficulty, it at least seems clear that the latter is not one of any considerable magnitude. (G. J. R.)

INSTITUTE OF FRANCE, an association constituted under the name of the *Institut National* by the

French Republican Convention, in October, 1795, to occupy a similar position to that of the old academies suppressed by an Act of the Convention, 8th April, 1793 (see ACADEMY). The affix to the word "Institut" has undergone a variety of changes corresponding to changes in the form of the government of France. The Institute owed its existence chiefly to the efforts of three persons, Lakanal, Daunou, and Carnot, and, according to the terms of the law by which it was founded, its purpose was to "advance the sciences and arts of research by the publication of discoveries and by correspondence with other learned societies, and to prosecute those scientific and literary labors which shall have for their end general utility and the glory of the republic." It was composed of three classes—the first for sciences physiques et mathématiques, the second for sciences morales et politiques, and the third for littérature et beaux-arts. Originally it consisted of 144 members (the 48 nominated by the Convention electing 96 others), an equal number of associates in the provinces, and 24 foreigners of distinction who held the position of correspondents. Each class was divided into several sections, 6 members and 6 associates being assigned to each section. The first class was composed of ten sections, viz., (1) mathématiques, (2) arts mécaniques, (3) astronomie, (4) physique expérimentale, (5) chymie, (6) histoire naturelle et minéralogie, (7) botanique et physique générale, (8) anatomie et zoologie, (9) médecine et chirurgie, (10) économie rurale et art vétérinaire. The second class was composed of six sections, namely, (1) analyse des sensations et des idées, (2) morale, (3) science sociale et législation, (4) économie politique, (5) histoire, (6) géographie. The third class consisted of eight sections, viz., (1) grammaire, (2) langues anciennes, (3) poésie, (4) antiquités et monuments, (5) peinture, (6) sculpture, (7) architecture, (8) musique et déclamation. To the first class were thus assigned 60 members and as many associates, to the second 36, and to the third 48, the foreign correspondents being divided equally among the classes. No member was permitted to belong to more than one class; but any one might be present at the meetings and assist in the labors of the other classes. The Institute was installed at the Louvre in the building formerly occupied by the Académie Française, but in 1806 its locality was changed to the College des Quatre-Nations. The First Consul on the 23d January, 1803, decreed for it a new constitution, the leading features of which were—that the approval of the head of the Government was essential in the election of members; the suppression of the second class; and a redivision into the four classes of (1) sciences physiques et mathématiques, (2) la langue et la littérature Françaises, and (3) histoire et littérature anciennes, (4) beaux-arts. The first class was composed of the ten sections of the old first class, and an additional section of geography and navigation with 3 members, with power to nominate 100 correspondents. The second class was composed of 40 members not separated into sections. The third class was composed of 40 members and of 8 foreign associates, and had the power to nominate 60 correspondents. The fourth class, which was composed of 28 members and of 8 foreign associates, was divided into five sections:—peinture with 10 members, sculpture with 6, architecture with 6, gravure with 3, and musique (composition) with 3 members. It had the power to nominate 36 correspondents. All classes had power to elect a stipulated number of members from the other classes. After the Restoration Louis XVIII. on the 21st March, 1816, decreed the revival of the names of the old academies to the four classes of the Institute:—(1) L'Académie Française, corresponding to the old second class; (2) L'Académie royale des inscriptions et belles lettres, corresponding to the third class; (3) L'Académie royale des sciences, corresponding to the first class; and (4) L'Académie royale des beaux-arts, corresponding to the fourth class. On the 5th March, 1833, a fifth academy was added to the Institute,—L'Académie des sciences morales et politiques, corresponding to the second class suppressed by Napoleon. As restored, it was composed of 30 members, with a minimum of 30 and a maximum of 40 correspondents. It was divided into five sections, viz., (1) philosophie, (2) morale, (3) législation, droit public, et jurisprudence, (4) économie politique et statistique, (5) histoire générale et philosophique.

Each academy has its own special jurisdiction and work, with special funds and one or more perpetual secretaries, in addition to which there is a general fund and common library, which, as well as other matters connected with the Institute as a whole, are managed by a committee chosen in equal numbers from each of the academies. Matters of common interest to all the academies are discussed at a general meeting of the Institute, and a *séance publique annuelle* takes place on the 25th October, the anniversary of the organization of the Institute. All the expenses of the Institute and the academies are defrayed by an annual sum voted by Government. Each member of the Institute receives an annual allowance of 1200 francs, and each secretary of an academy a salary of 6000 francs. A notice of the several academies is given in the article ACADEMY. See also FRANCE, vol. ix. p. 454.

INSURANCE.

INSURANCE is the system or machinery by which it is sought to guard against the pecuniary consequences of certain accidents to which men are liable, such as the loss of property by fire or shipwreck, or the loss of future earnings through disablement or premature death. Insurance does not attempt to prevent these accidents, nor even to protect men against all the consequences of them. It deals only with the main pecuniary loss which such accidents are fitted to occasion, provides for it beforehand, practically distributes it among the persons who are more or less exposed to the same risk; and so, when the accident does light on any one of them, its pecuniary effects are neutralized or greatly mitigated.

The three chief developments of this system—Fire, Life, and Marine Insurance—are separately treated in the following articles. A very important application of the principle has been treated under the heading FRIENDLY SOCIETIES.

Besides the above branches of insurance, which have attained immense proportions in almost all civilized countries, there are many other applications of the principle which have been tried with greater or less success. The conditions which seem necessary to success (in addition to good administration) are chiefly these:—there must be a risk of real loss which it ought to be beyond the power of either the insurer or the insured to avert or to hasten; a large number of persons must be liable to the like risk; the accident contemplated must be likely to fall on a comparatively small number of the persons exposed to the risk of it; the probabilities of its occurrence must be capable of being estimated beforehand with some approximation to certainty; the loss apprehended must be so considerable when it does occur as to be worth providing against; and the cost of that provision must be comparatively so small as not to be prohibitive.

Accident Insurance.—Ordinary life assurance protects against the pecuniary loss arising to a man's family or creditors or others by his death, whether that arise from accident or disease; but it has been found that a separate insurance against the consequences of accident meets the requirements of a large class of persons. A company was established in London in 1849 for insuring against the consequences of railway accidents—the Railway Passengers Assurance Company. In return for a payment of 3d., 2d., or 1d. made by first, second, or third class passengers respectively, for insurance during a single journey, it undertook to pay £1000, £500, or £200 in case of death by such an accident, or a certain weekly allowance in respect of personal injury not resulting in death. In 1856 the business was extended to embrace accidents of all kinds, and there came into use a system of yearly payments proportioned to the degree of risk supposed to attach to various occupations or other conditions of life. Many other similar companies have since been established, and at the present time (1881) there appear to be about eleven such offices in the United Kingdom. The amount insured by them is estimated at nearly £100,000,000 sterling, and their yearly income is between £400,000 and £500,000. The claims absorb about 50 per cent. of the premiums, the remainder, after paying expenses necessarily large, being the profit. Various schemes are at present being organized, in consequence of recent legislation, to enable employers to insure against risk from injuries suffered by their work-people.

The business of insuring against accidents has been developed in Canada, Victoria, and New South Wales, as well as in France, Germany, Switzerland, and the United States. In the country last mentioned the premium income of the principal office engaged in this business was in 1879 close on a million of dollars.

Fidelity Guarantee.—The guarantee of employers against the fraud or insolvency of their servants has of late years become a considerable and useful department of insurance business. Private suretyship is attended by many evils, and a bond of indemnity by a joint-stock company, although it has to be purchased by a yearly payment, is now generally preferred. Such a bond is not granted without previous inquiry as to the character of the applicant and the checks which the employer is to use. Seven institutions in the United Kingdom undertake this description of business; some of them insure only against loss arising from embezzlement, while others protect the employer against any failure to make good the sums entrusted to an employé. The yearly premiums required range from 10s. to 60s. per cent. of the sum guaranteed.

Various Minor Forms of Insurance.—In those parts of the British Isles which are exposed to violent hailstorms offices have been established successfully for insurance against the loss which these often occasion. Efforts have been made also, not always with equal success, to protect farmers and other owners of horses and cattle against the loss arising from accident or disease among these animals. It has been attempted also to insure traders against loss from bad debts, and house-owners against loss of rent and against defective titles. No fewer than thirteen offices, mostly local in their operation, insure against loss from the breakage of plate-glass, and three against the loss from explosion of boilers. In former times, when men were liable to be drawn to serve in the militia but might purchase a substitute, a system of insurance was established to provide them with the necessary funds. These developments of insurance, however, are of an importance quite insignificant compared with the three great departments now to be dealt with.

I. Fire Insurance.

Fire insurance is a matter of practical interest to a far larger number of persons than either of the other two great departments of insurance—life or marine. There are few persons to whom, in the absence of insurance, the destruction of their dwellings or of their household goods would not be a serious calamity, while to the merchant or manufacturer the burning of his premises or stock or machinery might be ruinous. No age or country has been exempt from such fatalities, and no watchfulness has been able to prevent them. Some protection against the pecuniary consequences seems an essential condition of any extended system of manufactures or commerce.

Fire insurance, however, as an organized system, has had an origin comparatively recent. There are traces, indeed, in earlier times of enforced or voluntary contributions towards the relief of sufferers by fire, but it is only about the beginning of the 17th century that we hear of proposals being made for a more systematic provision, and it was not till after the great fire of London in 1666 that these proposals took practical shape. This seems at first to have been in the form of underwriting by individuals or by clubs, and some attempts were made to engage the corporation of London in a scheme of fire insurance; but in 1681 the first regular office for insuring against loss by fire was opened by a combination of persons "at the back-side of the Royal Exchange," and it was followed shortly afterwards by another. Of the insurance offices that still survive, only one, the Hand-in-Hand, dates from the 17th century (1696); five date from the first half of the 18th century, the Sun (1710), Union (1714), Westminster (1717), London (1720), and Royal Exchange (1720); while only three date from the second half of that century, the Salop (1780), Phœnix (1782), and Norwich Union (1797). The first fire office in Scotland was established in 1720, the first in Germany in 1750, and the first proprietary company in that country in 1779; the first office in the United States was established at Philadelphia in 1752, one of its early directors having been Benjamin Franklin; the first in France dates from 1816, and the first in Russia from 1827.

The growth of fire insurance business in Britain did not receive much assistance from Government. At a very early period, in 1694 under William & Mary, a stamp duty was imposed on fire policies (now reduced to the nominal rate of one penny), and in 1782, during the administration of Lord North, fire insurances were made liable to an annual duty at the rate of 1s. 6d. for each £100 insured. This tax, which was collected by the offices along with their premiums and accounted for by them to the exchequer, was increased in 1797 to 2s. per cent., in 1805 to 2s. 6., and in 1816 to 3s., at which rate it continued for about fifty years. It was strongly objected to as a discouragement to prudence, and as disproportionate in rate to the cost of insurance which it was tacked to; but as it was easily collected, and yielded nearly two millions a year (£1,714,622 in 1863), it naturally died hard. In 1864 it was partially remitted, and it expired finally in 1869. The returns of the duty enable us to measure in some degree the progress of fire insurance in the United Kingdom during the eighty-five years of its incidence. Some descriptions of property, such as agricultural produce, were exempt from duty and do not appear in the returns, nor do the sums insured on property situated out of the United Kingdom; but the amount insured by British offices on which duty was paid was

In 1783	about	£135,000,000	In 1840	about	£645,000,000
" 1800	"	200,000,000	" 1860	"	1,000,000,000
" 1820	"	427,000,000	" 1868	"	1,430,000,000

At the present time (1881) there appear to be about sixty offices established in the United Kingdom for insuring against loss by fire either alone or in conjunction with life or marine insurance. A few of these are of very recent origin. The number does not include several foreign companies doing business in Great Britain.

Excepting by the imposition of the duty now repealed, the British legislature has not interfered with the business of fire insurance. Any number of persons may at the present time engage in this business with or without capital, nor is there a necessity even for the publication of their accounts. By the Life Assurance Companies Act of 1870, a deposit of £20,000 is required on the establishment of a life office; certain returns also must be made to the Board of Trade for presentation to parliament, and these regulations apply to offices which conduct fire in conjunction with life insurance, as well as to purely life offices. One consequence is that, while the results of the fire insurance business of these compound offices are published regularly, those of purely fire offices need not be published, and several of the oldest and most important fire companies do in fact keep their accounts strictly private. There is no reason to suppose, however, that their experience differs materially from that of the compound offices whose figures are open to us. From the returns of thirty of these it appears that their aggregate income from fire premiums in the seven years 1870–76 was as follows:—

1870	£3,765,000	1874	£5,824,000
1871	4,733,000	1875	6,072,000
1872	5,366,000	1876	6,162,000
1873	5,600,000		

The increase in six years was therefore nearly two millions and a half of yearly income, the premiums in 1876 being about 63 per cent. more than in 1870. There are no means of ascertaining how far this increase arises from the insurance of property abroad, which is no doubt a considerable item, or from an increase in the quantity of insurable property within the United Kingdom, or in the proportion of it which is insured, or in the average rates charged for insurance, but no doubt all of these causes were at work. It may be mentioned here that the thirty offices to which the above returns relate have a subscribed capital of about 40 millions, and cash assets available for fire losses, not including their life assurance funds, amounting to 20 millions. They have therefore funds in hand equal to more than three years' income from premiums. Another return gives the premium income of forty-five British offices in the year 1879 as £8,271,000, their losses as £4,349,000, their expenses as £2,426,000, and their net profits irrespective of interest as about £1,500,000, or 18 per cent. of the premiums. The whole premium income of British fire offices is probably nearly 10 millions sterling, and the amount insured may be taken at from four to five thousand millions.

The returns of the London Fire Brigade enable us to approximate to the amount of insurances effected on property within the metropolitan area. In 1866 the sum insured was about 316 millions; in 1871, 440 millions; in 1878, 605 millions; and in 1879, 624 millions.

The essential principle of fire insurance is the distribution of loss. It does not aim, directly at least, at the prevention and only in a secondary way even at the minimizing of loss; but what it seeks to accomplish is that such losses as do occur shall not fall exclusively, and possibly with overwhelming effect, on the owner of the property destroyed, but shall be borne in easy proportions by a large number of persons, who are all alike exposed to the risk of a similar catastrophe. This work of distribution is capable of being effected in more ways than one. It might be undertaken by the state or by a municipality, and this plan has been tried in several countries, notably in the canton of Zurich. There it applies to buildings only, not to their contents. The Government insures, and raises the necessary funds for meeting losses by a ratable tax on the owners. Where, as in this case, the exact sum needed is raised and no more, the system is practically one of mutual insurance administered by the cantonal authorities. Such a system yields this collateral benefit that the authorities, and indeed all house owners, become interested in the prevention and extinction of fires, and in Zurich accordingly the construction of buildings is carefully watched and regulated; but the results do not indicate any remarkable measure of success. The rate of assessment in 1870 was nearly equal to 2s. 6d. sterling per cent. The difficulties of carrying out such a system with equity, especially in a great community, seem almost insuperable. To assess the cost fairly it would be necessary, not merely to value each individual building, but to measure the degree of risk it was exposed to from its construction, its surroundings, its uses, and its contents. To place in the hands of public functionaries the power to do this, as well as to adjust the amount of compensation to be paid in the event of a fire, would be a course attended with manifest evils. Still greater would be the difficulty of applying the same principle to household goods, merchandise, and machinery; and, if these must be insured on some other plan, there seems little to be gained by setting up a different system for the insurance of buildings alone.

There is, however, a natural temptation presented to particular classes or communities to speculate in the insurance of their own property, in the hope of making a profit, or at all events of saving for themselves what would go as profits to the companies which would otherwise insure them. Sometimes this temptation seizes the inhabitants of a particular town, sometimes the persons interested in some particular trade, sometimes an ecclesiastical body. A community which has taken out of the hands of joint-stock companies the supply of its own gas or water, and finds itself as well served as before, perhaps better served and more cheaply, is apt to think that it may insure itself against fire as well. But, besides the complications in the problem which have been already alluded to, and which require technical skill and extended experience for their equitable solution, there are few bodies or communities which possess a sufficiently wide area to make insurance profitable or even safe. If there had been such a system at Boston or Chicago or St. John when these considerable cities were ravaged by fire, the effects would have been still more disastrous to them than they were. Certain classes of property again seem liable almost to epidemic fires, from causes which are often not far to seek; and if, for example, the owners of any particular class of mills were to combine in a scheme of mutual insurance, they might find that, besides the great difficulty of agreeing on how each mill was to be rated, or on the compensation to be awarded on the occurrence of a fire, they were exposed to exceptionally numerous claims just when their own trade was most depressed, or when their relations with their work-people already loaded them with sufficient anxiety. Schemes of so-called mutual insurance are tried from time to time, but scarcely ever without being based on a subscribed or paid-up capital (the contributors to which have to be remunerated), or without looking for outside business to give breadth and ballast to the enterprise.

Accordingly the system of fire insurance which has virtually superseded all others, and has contributed most to the public benefit, is that which is conducted by joint-stock companies, offering to the insured the guarantee of their capital and other funds, and looking to make a profit by the business. It is a department of commercial activity eminently suited for joint-stock enterprise, requiring for its success, and indeed almost for its safety, that its transactions should be various in character and spread over wide areas of space and time, and be invested with a certain amount of publicity, and enjoy that prolonged existence which attaches more to corporate than to individual effort.

Fire insurance as a business consists in undertaking a certain risk more or less considerable in amount, in return for a comparatively small sum, received beforehand, called the premium. While the amount of risk undertaken is strictly limited to the sum insured, the degree of risk is an element extremely difficult to measure, and liable to much fluctuation. Whether of ten thousand houses or shops, or stores, or factories, ten will be more or less injured every year by fire or a hundred is a matter partly of experience, but partly also of conjecture and, as we say, of chance. Assuming that the proportion would always be the same under precisely the same circumstances, not perhaps every year but on an average of years, the questions remain whether the circumstances will always be the same, and whether if they be the one thousand cases on which we have made our own calculations are a sufficient basis for dealing with ten thousand cases. The slightest observation reveals an endless diversity in the risks undertaken, and, even if an absolute law could be reckoned on, the risks would require careful and accurate classification before the law could be deduced. But, in point of fact, the risks are always changing. If we take what from an insurance point of view is the simplest and safest "risk," a private dwelling house in a large town, the question suggests itself, How has this risk been affected by the age of the building, the character of the occupants, the introduction of gas or paraffin or lucifer matches, by the proximity of more dangerous property, and by the improvement or deterioration in the public supply of water and the public arrangements for extinguishing fires? Infinitely greater changes take place in the degree of risk attending warehouses and manufactories, and many of these developments are of an unexpected character. The great fire in Tooley Street, London, in 1861, was aggravated by a prodigious escape of burning tallow, which literally set the Thames on fire, and long defied all efforts to extinguish it. More lately at Leith a highly inflammable spirit recently introduced into trade exhibited similar characteristics. At Newcastle a fusion of nitrates of soda or potash mixed with burning timbers caused a prodigious aggravation of a fire; and at Glasgow and elsewhere the fine flour dust of a corn mill, when mixed with a certain quantity of atmospheric air, was unexpectedly found to be as explosive as gunpowder.

But the speculative hazard of fire insurance as a commercial enterprise is limited by a very important circumstance. The contracts, in the United Kingdom at least, are seldom made for a longer period than one year, and often for less, and need not be renewed on either side unless their safety and reasonableness are confirmed by experience, so that from day to day the insurance company is able in a measure to revise its terms, and to correct the errors arising from imperfect data or a too sanguine generalization. The business on the whole has been a profitable one. There have been comparatively few absolute failures of fire insurance offices in Great Britain, and none of any magnitude; nor do British companies regard it as any distinction that "they have always paid their losses in full." The returns of those companies whose accounts are published indicate general prosperity, and the quotations of the share market and other circumstances show that the companies whose accounts are not made public have had at least equal success. The thirty companies whose experience has been already quoted received in fire premiums during the seven years 1870–76 about 37½ millions sterling, and paid away for losses by fire about 22 millions, or 58·7 per cent. of the premiums received. After providing for expenses, there must have been a satisfactory balance of profit in proportion to the capital at risk.

The conditions of the contract between a fire office and the insured are regulated partly by the terms of the document known as the policy, which embodies them, and partly by law outside these terms, resulting from custom, from statute, or from legal decisions. We will endeavor to set forth as succinctly as possible some of these conditions, having regard chiefly to British contracts.

It is in the first place a contract of indemnity. The insured is guaranteed against loss by fire to the extent of the sum agreed on, but he is in no event to receive more than he has lost, or to make any profit by the occurrence of a fire. The sum named in the policy is not the measure but the limit of what he can recover. Nor does his policy cover all the loss he may sustain, for it will not in any case protect him against consequential damage, such as the loss of trade or of prospective profit; and if he desire to recover, not merely the value of a building, but the loss he will sustain through its being temporarily untenantable, he must insure specially against that risk. He must have some substantial interest in the property he insures, but it need not be that of ownership, for, if he might lose as tenant or mortgagee or in any other capacity, he may insure against that loss; and he may insure against the loss which others would sustain for whom he holds the property in any fiduciary character. It is loss by fire only that is insured against, not loss by a fall in the market value of property or by natural tear and wear. If property which was worth £1000 has come to be worth only £700, and is then destroyed by fire, it is £700 and not £1000 that is recoverable under the policy. In some cases loss by lightning and by explosions of gas are insured against, even where there has been no fire in the ordinary sense. It is the value at the time of the fire, or rather the difference in value which the fire has occasioned, that becomes the sum payable, provided it do not exceed the sum insured. It has been sometimes tried to have "valued policies" by which the sum to be paid in the event of the property being destroyed is fixed definitely beforehand; but the system has been felt to be open to grave objections; for, apart from the labor and cost of valuing a thousand properties in preparation for the total destruction of four or five, it is obvious that, if the value fixed is less than the real value, there is no advantage to the insured, but the contrary; and if it is greater than the real value, then no doubt the insured might make a profit by a fire, but this would offer an inducement to carelessness, if not to incendiarism. In the United States, however, several State legislatures have been so imprudent as to enforce the issue of "valued policies."

According to the general practice of insurance in Great Britain, the insured recovers his loss up to the amount of the policy, although the property may not have been insured to its full value. A different rule prevails on the Continent and elsewhere, and even in England under exceptional circumstances, and wherever several unconnected properties or parcels of goods are insured under one sum. In these cases the rule of "average" is applied, by which the insured recovers only such proportion of his loss as the total sum insured bears to the total value of the property covered. The effect of this rule is virtually to compel persons to insure their property to the full amount of its value, unless they are willing when any loss occurs to bear a share of the loss. Under either system, if property is not fully covered, the owner is to the extent of the deficiency his own insurer; but under the one plan his liability to loss begins only after that of the insurance company has been exhausted, under the other his liability and that of the company run parallel from the first. The difference is most material where the loss is only partial, and practically the English rule is equivalent to a considerable reduction of rate. There are weighty reasons for believing that it might be for the advantage both of the insurance offices and the public to introduce more widely the *pro rata* principle, with a corresponding reduction of the nominal scale of premiums, or even to enforce a participation of risk on the part of the insured.

The contract of insurance is one of good faith. The insured is bound to disclose all special circumstances of risk attaching to his property, and ought to have them described in the policy, otherwise its validity may be endangered. He is bound, moreover, to communicate any change of circumstances which may affect the degree of risk. Special hazards affecting particular kinds of property are often specially warranted against.

Companies do not insure against the loss occasioned by invasion, foreign enemy, civil commotion, riot, or any military or usurped power; and there are some kinds of property which they will not insure,—ready money, books of accounts (their value as documents), bank notes, stamps, bills, bonds, and other written securities.

The almost universal practice in England is to insure a separate sum on each distinct kind of property insured, as on a building and on its contents, on mercantile stock, and on furniture in private use. The same rule prevails with respect to all properties not involved directly in the risk of one fire. Thus two contiguous buildings or their contents may be insured for one sum if the buildings communicate with each other internally or have a common roof, but otherwise they must be separately insured.

Very important questions arise out of the circumstance that the same building or goods may be insured by different persons, with various offices, and under dissimilar conditions. Thus a house may be insured by the landlord, the tenant, and the mortgagee; goods may be insured by the owner, by a creditor holding a lien over them, and by the warehouseman or other person who may be responsible for their custody. Where the owner alone has effected insurances, these may be so varied in their character as to give rise to perplexing questions. A merchant may have insured with one office wines in a specified warehouse A; with another, wines and spirits in the same warehouse for one lump sum; and with a third, wines only, but in all or any of the warehouses A, B, and C, subject to the conditions of average. The questions that arise under such circumstances owe their solution as much perhaps to the honor and fair dealing of the several offices interested as to any settled rules of law, but the general practice may be shortly stated. As between a policy covering a specific parcel of goods or goods in a specified place and another embracing a wider range subject to average, the former is exhausted before liability attaches to the latter. As between a policy covering goods in A and B and another covering goods in A, B, and C, if a fire occurs in A or B liability attaches first to the more restricted policy, provided the more extended liability of the other is not merely nominal. On the other hand, if one policy insures stock and machinery together (but without the condition of average), and another insures one or both of these separately, liability attaches to both policies *pari passu;* but the former is placed at some disadvantage in being obliged to contribute ratably to its whole amount with certain limitations, as against each of the separate items of the other. Where the same property is insured under similar conditions with more than one office, it has been the aim of the companies to provide that the loss shall be borne by each in proportion to the sum insured, whether the several insurances may be in favor of the same person or of several persons having different interests. It is plain that if it were in the power of two persons, having each some sort of insurable interest in the same parcel of goods, so to insure them as that each might recover their full value, the goods might come to be paid for by the offices twice over, and it might become the interest of one or both of the persons that they should be burned. The "contribution clause" of policies is intended to guard against this. It has lately received an unexpected interpretation which limits its application to insurances in which the interests insured are identical, while protection against double payments is afforded by another principle, namely, that each person insures only his own special interest. The utmost possible interest which M, N, and P can have in any given property cannot exceed the present value of the property; each may recover what he himself has lost by its destruction, whether he be owner, or mortgagee, or depositary, but he deals separately with the office that insures him, without reference to what other insurances may have been effected by other persons having a different kind of interest in the same property. The application, however, of these principles is often matter of extreme difficulty, and has scarcely yet been definitely settled.

The adjustment of a loss when a fire occurs is not unattended with difficulty, even where there are no such complications as those just referred to. To ascertain the quantity, the quality, and the value of property injured, and the degree of injury, is often a work of no little anxiety. Its destruction has swept away the readiest proof which could have been given; or, where partial damage only has been sustained, it is often scarcely capable of exact measurement. The insured is naturally bound to state and prove his claim; and the office, while exposed on the one hand to exaggerated and even to fraudulent demands, may on the other endeavor to exact from an honest claimant details and evidence which it is scarcely possible for him to give. Fortunately for both parties to the contract, there are strong motives on either side tending towards a reasonable adjustment. In most cases the office is guided by the advice of an independent professional valuer, who, while attending to the interests of his employers, has a natural desire, even apart from his instructions, to conciliate the claimant, and to avoid landing the company he represents in troublesome controversies. Claims which cannot be adjusted in this way are usually submitted to arbitration, and it is a condition of most policies that both sides must refer the quantum of loss to an arbiter or arbiters. Few claims find their way into the courts of law, and those only where some principle is involved, or where the claim is thought to be fraudulently overstated, or where the still more serious objection is taken that the fire has been the wilful act of the insured.

Many troublesome questions are rendered more easy of solution by the condition that it is in the power of the company to reinstate property rather than to pay the value of it. The insured has not the option of requiring reinstatement. In general an office prefers to settle a claim by payment in cash, but an offer to reinstate may be a convenient as it is a perfectly fair reply to an exaggerated demand, and may adjust the pretensions of competing claimants. The insured is not entitled to "abandon" his property, and the company is not bound to take on itself the care or risk of damaged property; it is for the insured to make the most of the "salvage," and to deduct the value of it from his claim, but in practice it is sometimes found desirable to relieve him of this duty.

A part of the insurance system which has developed into great magnitude is the practice of reinsurance. No one company, however large its resources, deems it prudent to undertake a risk to an unlimited amount in connection with any one set of goods or one locality. An office might restrict its liabilities by refusing to insure to a larger amount than what it pleased to run the risk of, but the convenience of the insured and the interest of its own agents, to say nothing of other considerations, make it difficult for any office so to limit its responsibilities. It therefore issues a policy for the amount proposed to it, but reinsures a part with some other office or offices. Business to a very large amount is exchanged in this way, and there are some offices which professedly, and some which practically, live by the premiums paid over to them by other offices. The principal British offices have established a code of laws for the regulation of these transactions, and a court of arbitration for the decision of such questions as may arise among themselves in connection with them. They are often also matter of special contract between office and office. The system is of some benefit to the public. In the earlier periods of fire insurance, when a large sum had to be insured, a higher rate was charged; but this has long ceased to be the rule. A man who wishes now to insure a large amount has not only no extra rate to pay, but has not to take the trouble of arranging with numerous offices, or, if a fire occurs, of adjusting his loss with numerous offices.. He can usually, if he pleases, obtain a policy from one company for the full sum he needs to insure, and the company takes all the trouble and risk of distributing the liability, a distribution with which he has nothing to do. He may even benefit in another way, for when a loss occurs he has on the whole, perhaps, a better chance of being liberally dealt with than if he had to make a direct claim on many offices.

What has been said hitherto has had reference chiefly to one side of the fire insurance contract—the obligations undertaken by the company. The consideration they receive in return is the payment made by the insured called the "premium." The premium is calculated at so much per cent. of the sum insured, and is usually paid once a year, at one or other of four quarter days; but many insurances are effected on mercantile property and on ships for periods less than a year—ten days, one, three, or six months—the rate in such a case being higher than an aliquot part of the yearly rate; and insurances may be effected for seven years by a payment of six times the yearly rate, and for other periods at a proportionate discount. Insurances effected for a year, and stated to be renewable, practically remain in force for fourteen or fifteen days after the expiry of the year; that is, they may be renewed by payment of the premium within these "days of grace," and if a fire occurs in the meantime the company will be liable. This will not happen, however, if an intention not to renew has been manifested on either side.

The rate of premium varies with the supposed risk, and in Great Britain runs from 1s. 6d. per cent. yearly, the rate for first-class dwelling-houses and ordinary private furniture, to six or seven guineas per cent. The highest British rates are what are charged for some descriptions of corn-mills and sugar refineries, and for Turkey-red dye-works. Large classes of property are insured at the ordinary "hazardous" rate of 2s. 6d., or "extra hazardous" rate of 4s. 6d., but certain descriptions of property are specially and more elaborately rated. This has been done to a considerable extent by common agreement amongst the offices, and the arrangements are known as the "tariff system," which requires here a few words of explanation.

We may suppose the question to arise, What ought to be paid for insuring a cotton-mill, or a flax or woollen mill, or a weaving factory, or a wharf or warehouse in some large city? The experience of any one office scarcely affords adequate data, and a rate based on the combined experience of many offices has a greater chance of being at once safe and fair. The problem, indeed, is a more complicated one than what has been already said would indicate. The property to be insured may consist of several distinct buildings and the contents of them: one building may be devoted to operations involving in a high degree the risk of fire; in another the processes carried on may be more simple and safe; a third may be used only for the storage of materials having little tendency to burn. These several buildings may be more or less connected with each other—under the same roof, under different roofs but with internal communications, contiguous but without any communications, detached but still within reach of fire. Of two mills one may work on fine materials, the other on coarse; in one the machinery may be driven twice as fast as in the other; in one the most hazardous processes may be carried on in the heart of the building, in the other they may be so treated and so guarded as to involve the rest of the property in no peculiar danger. Fairly to measure these various hazards it has been found necessary that the experience and skill at the command of many companies shall be combined, and that the rates shall be the result of consultation and a common understanding.

Now it is clear that no office will contribute its skill and experience to such a common stock if the effect is to be that other offices may avail themselves of the information in order to undersell it. Consultation about rates and a common understanding necessarily involve a reciprocal obligation to charge not less than the rates thus agreed on; in other words, a tariff of rates is developed to which each office binds itself to adhere. The system tends to restrain and moderate the competition for business which inevitably and to some extent properly exists among the companies, and its value to them is manifest. But it is also of service to the insuring public. At first sight it might seem that free competition would suit the public best, and that a combination among the offices must tend to keep up rates, and to secure for the companies excessive profits, but a little consideration will show that this is a mistake.

It is an unquestionable truth, though one often lost sight of, that all losses by fire must ultimately be borne by the public. The insurance companies are the machinery for distributing these losses, nothing more. If the losses fell on them, their funds, large as they are, would speedily be exhausted, and the service which they render to the public would come to an end. To those who require insurance against loss by fire it must be a manifest advantage that they should have many sound and prosperous offices ready to accept their business, and no less able than desirous to earn or to retain the public favor by fair and liberal conduct. A necessary condition of this state of things is that the rates of premium paid for insurance should be remunerative to the offices, and the main object of the tariff system is to secure such remunerative rates.

This it endeavors to do by two methods,—by an agreement as to what rates are to be charged, and by affixing such a penalty to dangerous constructions, substances, and processes as to induce, if possible, a lessening of the danger. In other words, and reversing the order, it seeks to diminish the risk of fire, and to secure adequate payment for what risk remains. There can be no doubt as to the benefit the public derive from the former of these, in having pointed out to them, not on the authority of one office, still less on hesitating and contradictory authority, but with all the weight arising from the combined experience of numerous companies, that this or that method of construction, this or that combination of materials, this or that mode of conducting a manufacturing process, is attended by imminent hazard of fire, and in having the lesson enforced by a heavy pecuniary penalty. On the supposition that the offices are correct in their estimate of risks, the effect, and indeed the intention, of their rule is not so much to put money into their own coffers as to lessen the danger, and to save themselves in the first instance, and the owners of property ultimately, from the consequences of preventible fires.

These rules, as will readily be seen, must have powerful influences on trade and manufactures. Many individual warehouses and mills are, with their contents, insured for very large sums, £10,000, £20,000, £50,000, £100,000, and more. An additional charge of 5s. or 10s. per cent. in respect of a supposed increase of risk may mean a payment by the owner of several hundred pounds a year, and may operate as a complete veto on some arrangement or some machine which it might otherwise be desirable to resort to. The occurrence of a few severe fires in one town, followed by an increase of insurance rates, may have, and indeed has had, the effect of driving some branch of trade away to another locality, the seat of greater caution or better fortune. It is therefore obviously desirable that so important an influence should be exercised, not precariously or capriciously, but according to the combined wisdom and experience of those associations which may be supposed to understand the subject best, and which obtain their experience in the way that makes it perhaps of most value, by paying for it.

It is equally for the public benefit that rates of insurance should be fixed on some common scale. Suppose the system of unrestricted competition to be tried, the first effect will be a general and great reduction in rates. But it may be said, "So much the better for the insured; if the offices can afford this reduction of rate, it will only be a fair result of competition; if they cannot afford it, they will be the losers, but the public will gain; will the effect not be simply to reduce the rates to the paying point, and no further?" This would be all very well if the paying point could be absolutely ascertained or determined in any way beforehand, but the rate comes first and the losses come afterwards. In other businesses prices are based on some certainty as to the cost of production, but in selling fire insurance the cost is not known till after it has been sold. In a free competition it is the sanguine man's views which regulate the market price, and the rates therefore cease to be remunerative. The consequences are that some offices disappear altogether, others take fright in time to avoid ruin, though not to escape serious loss, persons who might establish new offices are deterred from doing so, the business gets the character of being a highly speculative and hazardous one, requiring extravagant profits to induce men to carry it on at all, and the public have to bear the cost. Unrestricted competition therefore is not for their advantage.

The combination we are considering has another beneficial effect; it serves to distribute the burden of losses fairly. If it is a just thing that cotton-spinners should bear all the losses that arise in cotton-mills, and not leave them to be borne by the owners of private dwelling-houses, or *vice versa*, it is well that the loss by each class of risks should be measured fairly. But, while the experience of any one office, taken by itself, furnishes a very imperfect criterion, each contributes its quota of knowledge and experience to the common stock, and the public get the benefit both of broad and trustworthy data, and of that peculiar and intimate acquaintance with each different class of property or process which the conductors of one company or another are sure to possess.

On the other hand, it is beyond question that no association of the kind will ever hold together a large body of independent societies except under the pressure of some necessity. No conventional or excessive rates can be maintained for any length of time. Some member of the union is sure to perceive that popularity and profit may be gained by introducing a lower rate, if a lower rate is manifestly sufficient, or a new company starts into existence to remedy the grievance. It is to be remembered, too, that the directors and shareholders who control the offices are likewise insurers, quick to raise the question of how far the rates they have to pay as individuals are justified by the risks run; and if it cannot be shown that these rates are a true measure of the risk, offices are soon constrained by a sense of justice or by self-interest or by pressure from without to mitigate them. In short, the association is a union bound together by necessity and tempered by competition.

Adequately to measure the risk of loss by fire demands not merely reference to an extended experience but a watchful regard to current changes. While the profits of fire insurance business fluctuate considerably from year to year, and seem even to follow cycles of elevation and depression, the tendency on the whole appears to be towards a growth of risk, although excessive competition among offices prevents the rates from rising in proportion. Among the causes are the prodigious increase in the use of lucifer matches; the introduction into commerce of such articles as jute and esparto grass and mineral oils, which are either highly inflammable, or have by themselves, or in combination with other substances, a tendency to generate combustion; the great speed of machinery; and the vast accumulation of property exposed to the risk of one conflagration, owing to the larger size of mills and warehouses and their concentration in particular localities. The very development of the insurance system may conduce to heighten the risk by lessening the motives to carefulness. It is difficult to form an estimate of the average rate of premium paid for property in the United Kingdom, but it is probably not much above or below 4s. or ·2 per cent. yearly.

When insurance companies were first established, and for a long time afterwards, they undertook not only to reimburse the insured for losses, but to extinguish fires. In one of the earliest prospectuses put forth (in 1684), there is the promise that "watermen and other laborers are to be employed at the charge of the undertakers to assist at the quenching of fires." A writer in 1690, describing the ingenious and useful invention of a fire insurance office, says, "They have a great many servants in livery with badges, who are watermen, and other lusty persons dwelling in several parts of the city, who are always to be ready when any sudden fires happen, which they are very laborious in and dexterous at quenching;" and De Foe, in an essay published in 1697, refers to the same subject. In 1708 when the Sun Fire Office was first projected, it was proposed that all persons insured with it should have a mark representing the sun nailed up against their houses, that the men whom it employed to extinguish fires and save property might direct their efforts specially for the benefit of the houses so distinguished. Marks of this sort were afterwards generally adopted by the offices, and are often to be seen even at the present day, though they no longer serve their original purpose. For more than a century and a half the insurance offices provided and kept up fire-engines at their own expense, not only in London, but in many provincial towns, where frequently no other means of extinguishing fires were available. At first each office provided its own engine, and much rivalry prevailed among the several brigades; but in London ultimately the offices combined to support in common a very effective and very costly fire brigade. This arrangement, however, came to be regarded as objectionable from public points of view, as it had long been distasteful to the offices themselves; and in 1866 the offices handed over their whole establishment to the Metropolitan Board of Works, by whom it has been greatly enlarged and extended, the cost being provided for partly by a contribution from the offices, partly out of the Consolidated Fund, and partly by the rates.

The views of the insurance offices on this subject have undergone a material change, and they have ceased to regard it as any part of their duty to extinguish fires, or to bear the cost of extinguishing them. That ought to be undertaken by the public through municipal or other local authorities, and it is understood that the law regards it as their duty to do so. Parliament is always ready to confer the necessary power of assessment; but there is a disposition on the part of municipal bodies to exact from the insurance offices, directly or indirectly, as much of the expense as they can. Considerable contributions are in this way levied in Liverpool, Manchester, Glasgow, and other towns, but the system is eminently to the disadvantage of the public. Whatever the offices are compelled to pay forms a portion of their general expenditure, which they must recover from the public, at least the insuring part of it, in the form of premiums. The amount would be more equitably levied by means of a general assessment, and would be more likely to be advantageously expended. The business of fire insurance is to meet the losses which happen by fire, not to prevent them; if losses are heavy, the rates of premium must follow; if by care and well-organized appliances losses are diminished, the competition among the offices will inevitably reduce the rates of premium. In other words, if the public themselves bear the cost of these appliances, they obtain the benefit of it in a reduced cost of insurance; if they transfer the burden to the offices, they have in the end to bear it themselves in the form of increased insurance rates. If there were, as there ought to be, an efficient fire brigade in every town and village, it is obvious that the insurance offices could neither bear the cost nor undertake the care of them, and the best arrangement would be that they should be wholly under local management and wholly at local expense.

But, while it is the business of the public authorities to extinguish fires, the insurance offices regard it as within their province to promote in other ways the safety of the property endangered, and accordingly in London, Liverpool, Glasgow, and other cities they have established at their own expense salvage corps, which act in alliance with the fire brigades, but whose special duty it is, not so much to quench a fire, as to diminish as far as they can the damage which may be occasioned to the property whether by the fire or by the water used to extinguish it.

It only remains to add, with reference to fire insurance in the United Kingdom, that public attention has from time to time been directed to the serious question of how far the crime of arson may be regarded as a consequence of the insurance system, and what can be done to prevent it. There can be no doubt that wilful fire-raising, with a view to defraud insurance offices, is not only a very common offence, but is probably on the increase. In 1867 the subject was inquired into by a committee of the House of Commons, and evidence was submitted to show that between 1852 and 1866 the proportion of fires which were suspicious, doubtful, and unaccounted for, had gradually increased from 34½ to 52½ per cent., while well-informed persons testified that the number of fires in insured property is greater in proportion than in uninsured. There is a general agreement that in the interests of the public the origin of all fires should be made the subject of organized inquiry, but there is a difference of opinion as to the proper machinery and as to the incidence of the expense. Of existing functionaries the coroner in England and the procurator-fiscal in Scotland seem the natural persons to conduct the needful investigations, but in neither case is the subject free from difficulties, which in England are enhanced by the want of a public prosecutor. Several attempts have been made to legislate on the subject, but hitherto without success, nor is the public feeling sufficiently strong to give the required impulse. Other crimes than arson thrust themselves on public notice, and all men see the necessity for inquiry and detection. This crime, when successful, too often destroys, not merely the evidence which would go to prove it, but the very circumstances which would indicate that a crime has been committed. The immediate sufferer, too, is probably some wealthy insurance company, whose case naturally excites little sympathy; it is seldom prudent, and sometimes scarcely safe, for the sufferer to insist on exceptional inquiries, and there is a general disposition rather to put up with a loss than to raise disagreeable questions likely to lead to nothing. But, as the honest portion of the community pay for all dishonest claims, it may be hoped that a due inquiry into the causes of fires will some day come to be regarded as a matter of grave public interest.

The general principles and practice of fire insurance are, in their main features, the same in most parts of the world. In the United States the business has been pursued with characteristic energy, and with some peculiarities of law and practice. As already stated, the earliest American fire insurance company was organized in 1752, and its policies during the first year covered a sum of $108,360 at an average rate of 1·17 per cent. At the present time there are within the State of New York alone upwards of eighty fire offices, having assets amounting to about 54 millions of dollars, and in the *Insurance Year Book* for 1880 there is a list given of about four hundred different native offices in the various States, but this does not include a large number of local offices of small dimensions, mostly established on the mutual principle. The number of fire insurance offices in the United States is probably about nine hundred. Of these a large proportion have a merely nominal existence, but on the other hand important foreign offices—British, French, German, Swiss, and Canadian—transact business in the States.

If sixty offices suffice to transact the insurance business of the United Kingdom and a great deal of foreign business besides, the existence of more than four hundred offices in the States indicates of itself that a large number of them must have very limited resources, quite unfit to cope with the disastrous fires which sometimes occur in the rapidly developed cities of America. The failure of an insurance office is therefore a more familiar event than in England, and it is this perhaps partly which has led to a system of Government supervision intended to guard the public against such misfortunes. Each State of the Union has its own regulations about insurance companies, its insurance department, its insurance commissioner, superintendent, or auditor, its system of accounts and checks and public notices, its fees, taxes, and requirements as to deposits. The trouble and expense to which offices are thus exposed, especially where they do business in many States, is very great indeed, while the resulting benefits are problematical. All attempts of this sort are attended with these disadvantages, that they interfere injuriously with honest and well-conducted companies, and afford but a feeble protection against those of a different class; that they involve the Government in the odium of failures which it is supposed to be their duty to prevent; that they lessen the sense of responsibility among those who control the offices, and the spirit of prudence and watchfulness among the public; and that they place in the hands of public officials a power and influence which are apt to be abused, and are always open to suspicion. More to be admired and imitated are the State regulations in America with respect to building operations, the extinguishing of fires, and the inquiring into their origin. The business of an insurance agent in America is more recognized than in England as a distinct profession, and the agent is entrusted with greater powers. More has been done to facilitate the working of insurance by the surveying and mapping of large cities, and there has been a greater development of periodical literature devoted to the subject.

Since 1866 a national board of fire underwriters of the United States has existed, and has proved of great service to the insurance offices and to the public. At the present time it is unfortunately suffering from disorganization, and there has been a consequent "shrinkage" of rates. It appears from the reports of the superintendent of the fire department in the State of New York that in the year 1879 the sums insured in the United States by the companies reporting to him amounted to 6767 millions of dollars, and the relative premiums to nearly 61 millions of dollars, so that the average rate of premium was ·9 per cent., or 90 cents for each hundred dollars insured. Fourteen British fire offices doing business in the States received in the year 1879 premiums to the amount of 11 millions of dollars, and paid losses of 7 millions. Their losses that year were 63 per cent. of their premium, and their expenses in America 31 per cent.

In Canada twenty-seven companies—Canadian, British, and American—made returns, which showed that in 1879 they had insured in Canada, including the maritime provinces, sums amounting to 385 millions of dollars. In the eleven years ending in 1879, the premiums received had amounted to nearly 33 millions of dollars, and the losses to 27½ millions, and the ratio of loss had been 84·16 per cent. This included the loss arising from the great fire at St. John, New Brunswick, in June, 1877, which cost the insurance offices 6½ millions of dollars.

In France there were at a recent date thirty-two proprietary and about twenty mutual fire insurance offices. Of the thirty-two offices founded on capital three are provincial offices, and the others are established in Paris. Two confine themselves to reinsurance. From the returns made by twenty-three of these offices, including all the more important, it appears that in 1879 their income from premiums was about 92 millions of francs, and their losses 47 millions. The average loss during eleven years was 50 per cent. of the premiums. Many of the French offices have been extremely successful; and recently there has been a remarkable increase of new offices in that country.

The *Insurance Cyclopædia* of Mr. Cornelius Walford, a work now in progress, and of prodigious industry and completeness, is the best and almost the only available literary authority which covers the whole subject of this article. The *Law of Fire Insurance*, by Mr. C. J. Bunyon, is also of value. (J. M. M'C.)

II. Life Insurance.

The system of life insurance embraces a variety of contracts by which the insurers engage to pay capital sums on the decease of policy holders or nominees, in consideration of other sums received during their lifetime. These contracts may be divided into two classes,—(1) those in which the sum insured is certain to become payable, provided only the insurance is duly kept in force, and (2) those which are of a temporary or contingent character, so that the sum insured may or may not become payable according to circumstances.

Varieties of life insurance.

To the first of those classes belong the great bulk of the transactions of life insurance offices, namely:—

1. *Whole-Term Assurances on Single Lives.*—These are simply contracts on the part of the insurance office to pay a certain sum (with or without "bonus additions," as the case may be) on the death of the person named in the policy, whenever that may occur. The premium, or consideration for the insurance, is in most cases an annual sum payable during the whole continuance of the policy. It may, however, be arranged in various other ways,—as, for example, by a single payment at the commencement of the transaction; or by a limited number of contributions, each larger in amount than the annual premium for the whole of life; or by payment of a modified rate during a limited period and a correspondingly higher rate thereafter. Insurances for the whole term of life are more common than any other kind.

2. *Endowment-Assurances.*—Next to insurances for the whole term of life, these constitute the most numerous class of insurances on single lives. The sum insured is payable to the person named in the policy, if he should survive a certain period or attain a specified age, or to his representatives at his death, if that should occur before the time has expired.

3. *Insurances on Joint Lives.*—In these transactions two or more lives are included in the policy, and the sum insured is payable when either or any one of them fails.

4. *Longest-Life Insurances, or Insurances on Last Survivor.*—These also are effected on two or more lives, but instead of falling in by the death of any one of the parties, they do not mature until both or all are dead.

The second class of insurances described above consist principally of two kinds:—

1. *Temporary or Short-Period Insurances.*—These are effected for limited periods to cover special contingencies, the sum insured becoming payable only if death should occur within the time specified in the policy. Such insurances may be effected on single lives or on two or more lives, and (in the latter case) may be payable either if one life or all the lives should fail within the period, or only if one life should fail before another, as in the case to be next mentioned.

2. *Survivorship Insurances, or Insurances on one Life against Another.*—In these the sum insured is payable at the death of A if that should happen in the lifetime of B, but not otherwise. Should B predecease A, the transaction falls to the ground.

Besides these there are transactions of other kinds dealt in by life insurance offices—such as deferred insurances, where the risk does not commence until the expiry of an assigned period; deferred and survivorship annuities; insurances against issue, for the benefit of expectant heirs; and the like. The system is indeed adapted to nearly every contingency of a pecuniary nature connected with human life.

"Insurance" and "Assurance,"

It may be observed that, while life insurance has much in common with fire and marine insurance, there are some essential differences between it and them. The insurance of houses and goods against fire, or of ships and merchandise against the casualties of the sea, is a contract of indemnity against loss, and in like manner an insurance on human life may be regarded as indemnifying a man's family or his creditors or others interested against the loss of future income by his premature death. But it does not necessarily take the value of such income into account, nor does it relate to any intrinsic value of the *subject* of the insurance—the life of the insured party. Again, in fire and marine insurance loss may be either total or partial. In life insurance the event insured against cannot take place in any limited degree, and there is thus no partial loss. And again (in the first and larger of the two classes into which life insurances are divided) the event is certain to occur, and the time of its happening is the only contingent element. In the other kinds of insurance the events are wholly of a contingent character.

The idea of distinguishing in terms between contracts which differ so widely in reality appears to have early suggested itself. Mr. Babbage in his *Comparative View of the various Institutions for the Assurance of Lives*, published in 1826, says—"The terms *insurance* and *assurance* have been used indiscriminately for contracts relative to life, fire, and shipping. As custom has rather more frequently employed the latter term for those relative to life, I have in this volume entirely restricted the word *assurance* to that sense. If this distinction be admitted, *assurance* will signify a contract dependent on the duration of life, which must either happen or fail, and *insurance* will mean a contract relating to any other uncertain event, which may partly happen or partly fail. Thus, in adjusting the price for insurance on houses and ships, regard is always had to the chance of salvage arising from partial destruction."

The distinction proposed by Mr. Babbage has not always been observed. Some writers appear to prefer the term *insurance* where life is concerned as well as in other cases: some continue to use the terms indiscriminately; while other recent writers have sought to establish distinctions of a novel character between them. One of these is that a person *insures* his life, his house, or his ships, and the office *assures* to him in each of these cases a sum of money payable in certain contingencies. Another is that *assurance* represents the principle and *insurance* the practice. Of these two suggestions we prefer the former; but, as the more conventional distinction of Mr. Babbage is still very widely recognized, we shall adhere to it throughout the remainder of this article.

Mortality tables.

Calculation of Premiums.—The general principles of life contingency calculations are explained in the article Annuities, and it is there shown that such calculations are made by means of mortality tables, which exhibit the numbers of persons who out of a given number born or living at a particular age live to attain successive higher ages, and the numbers of those who die in the intervals. A full account of the numerous tables of this kind which have been framed from time to time does not fall within the scope of the present article, but, before passing on to show the application of mortality tables in the various calculations relating to assurances upon lives, it may be useful to mention those tables which have been chiefly employed by assurance offices.

Northampton Table.

Passing over the earlier tables of Halley, De Parcieux, and others, which for all purposes of calculation have long been obsolete,—and which, however much they contributed in their day to the development of assurance, possess now only an historical interest,—we pause first at the Northampton Table. This was constructed by Dr. Thomas Price from the registers kept in the parish of All Saints, Northampton, for the forty-six years 1735 to 1780. Owing to certain faults in its construction, the table gives the chances of death too high at the younger ages, and consequently requires large premiums for assurances; while at the more advanced ages the chances of death are disproportionately low. For a long time, however, this table occupied the foremost place as a basis for life contingency calculations of all kinds, and even after the introduction of other tables, which are now recognized as more accurate, it continued to receive a large share of popularity. The rates of many assurance offices of high standing were calculated from it, and until a comparatively recent date it remained in use by not a few of them.

Carlisle Table.

The Carlisle Table was constructed by Mr. Joshua Milne from materials furnished by the labors of Dr. John Heysham. These materials comprised two enumerations of the population of the parishes of St. Mary and St. Cuthbert, Carlisle, in 1780 and 1787 (the numbers in the former year having been 7677 and in the latter 8677), and the abridged bills of mortality of those two parishes for the nine years 1779 to 1787, during which period the total number of deaths was 1840. These were very limited data upon which to found a mortality table, but they were manipulated with great care and fidelity. The close agreement of the Carlisle Table with other observations, and especially its agreement in a general sense with the experience of assurance companies, won for it a large degree of favor. No other mortality table has been so extensively employed in the construction of auxiliary tables of all kinds for computing the values of benefits depending upon human life. Besides those furnished by Mr. Milne, elaborate and useful tables based upon the Carlisle data have been constructed by David Jones, W. T. Thomson, Chisholm, Sang, and others. The graduation of the Carlisle Table is, however, very faulty, and anomalous results appear in the death-rates at certain ages.

Equitable experience.

The mortality experience of the Equitable Assurance Society, the pioneer of the modern system of assurance, has formed the basis of several tables. Of these two in particular have been used to a considerable extent by assurance companies. The first was a table constructed by Mr. Griffith Davies and published by him in 1825. It was deduced from accounts given by Mr. W. Morgan, the actuary of the society, of the ratio which the death-rates among the members bore to those indicated by certain well-known tables at different ages. The other table was constructed by Mr. Arthur Morgan from the statistics of membership of the society from its commencement in 1762 down to 1829. This table was published in 1834.

Seventeen offices' experience.

Shortly afterwards a desire began to be pretty generally felt for a table of observations more extended than the statistics of any single office could supply, and accordingly a movement was set on foot in 1838 by a number of actuaries and others for collecting the experience of various offices "to afford the means of determining the law of mortality which prevails among assured lives." Seventeen offices agreed to contribute their statistics, which were found to embrace in all 83,905 policies, of which 44,877 were in existence at the time of giving in the returns; 25,247 had been "discontinued;" and 13,781 had fallen by the death of the persons assured. The results of the inquiry were in due time published, and upon them was founded a mortality table known as the Seventeen Offices' Experience Table, which came to be used to a considerable extent by assurance companies. A peculiarity of this table is that it is based upon the experience of the offices in regard to the number of *policies* which existed and became claims, and not the number of *persons* who were assured and died. There having been in many cases two or more policies issued on one life, the results are not necessarily the same as those which would have been obtained had each life been reckoned only once. The general agreement of the results with those derived from other data referring to persons, and not to policies, seems to show, however, that the peculiarity referred to does not materially affect the accuracy of the table as an exponent of the value of assured life.

English Life Tables.

Three English Life Tables have been constructed by Dr. William Farr from the official records of the registrar-general for England and Wales. The first, contained in the *Fifth Report of the Registrar-General* (1843), was founded on the census returns of 1841, and the deaths recorded in that year. The second table, contained in the *Registrar-General's Twelfth Report*, was based on the same census and the deaths of the seven years 1838 to 1844. The third table had a much wider basis than either of the others. It embraced the census returns of 1841 and 1851 and the deaths of seventeen years (1838–1854). This table, with an extensive series of monetary and other tables deduced from it, was published as a separate work in 1864.

Institute of Actuaries' Tables.

The next set of tables demands more special notice in an article like the present, as being the most important collection of observations yet made in regard to the mortality of assured lives. "Nearly a quarter of a century having elapsed since the period to which the combined experience of seventeen life assurance offices was collected, it began to be felt amongst actuaries and the managers of companies that a large mass of valuable materials had accumulated which, if combined, would tend to throw further light on the law of mortality amongst assured lives, and on other points affecting the interest and prosperity of assurance companies." Accordingly steps were taken by the council of the Institute of Actuaries, in co-operation with committees of the Association of Managers of Scottish Life Assurance Offices and of the Faculty of Actuaries in Scotland, "to collect and combine, as far as possible, the experience of the life assurance companies of the United Kingdom to the present time." This movement was begun in 1862, and in 1869 the results of the inquiry were published in a volume containing 282 pages of tabular matter, with a preface (from which the above quotations are taken) by Mr. Samuel Brown, then president of the Institute of Actuaries. The preface details the processes employed in collecting and arranging the statistics, and indicates the more important conclusions to be drawn from them.

The experience collected on this occasion embraced the returns of twenty offices—ten English and ten Scotch—the total number of lives assured being 160,426, of whom 26,721 had died, 45,376 had discontinued their policies, and 88,329 remained on the books of the several offices at 31st December, 1863, the date to which, as a rule, the observations were brought down.

From these statistics several distinct mortality tables were constructed, viz.:—

Table H^{MF}, comprising all the *healthy lives, male and female*, included in the observations,—the word "healthy" being used to denote those lives which had been considered eligible for assurance at the ordinary rates of premium.

Table H^{M}, comprising the *healthy male* lives only.

Table $H^{M(5)}$, comprising healthy male lives, but excluding from observation the first five years of assurance in every case.

Table H^F, comprising the *healthy female* lives.

Other tables of a subsidiary character were constructed, but they do not appear to have been put to any practical use.

The completed tables were published in 1872, together with an extensive series of monetary values deduced from them, and explanations by Mr. W. S. B. Woolhouse and Mr. Peter Gray respectively, as to the method of graduation employed in the formation of the tables, and as to the construction and application of the monetary values. In 1873 Mr. R. P. Hardy published a series of *Valuation Tables* based upon these data.

Scotch offices' experience.

It appeared to the two bodies in Scotland already mentioned that considerable advantage might result if the experience of the Scotch offices were separately ascertained, besides being merged in the general inquiry. This was accordingly done, and the results, arranged and tabulated by Mr. James Meikle, were published in a report (1869) by the joint committee appointed to collect the information. The investigation embraced 115,254 policies on 94,749 lives, of whom 12,443 had died, 19,284 had discontinued their policies, and 63,022 remained on the books of the ten offices at 31st December, 1863. These separate Scotch statistics were intended more particularly to illustrate the effects of the selection of lives for assurance. They have not been commonly employed as a basis for the calculations of offices. In 1872 Mr. Meikle published *Observations on the Rate of Mortality of Assured Lives*, in which the materials furnished by these statistics are exhaustively treated. This work forms a most valuable contribution to our knowledge of the subjects with which it deals.

The following tables will serve as a means of general comparison between the various mortality tables that have been mentioned:

I.—Table *showing the Number of Persons who, out of* 1000 *living at the age of* 10, *will live to attain the ages of* 20, 30, 40, *etc., according to the under-mentioned Mortality Tables.*

Age.	Northampton, 1780.	Carlisle, 1815.	Equitable (Davies), 1825.	Equitable (Morgan), 1834.	Seventeen Offices' Experience, 1843.	English, No. 3 (Males), 1864.	Institute of Actuaries' H^M, 1869.
10	1000	1000	1000	1000	1000	1000	1000
20	904	943	951	928	933	945	962

60	359	564	536	559	560	517	589
70	217	372	361	360	358	324	381
80	83	148	169	140	133	116	139
90	8	22	23	13	13	14	15

II.—Table *showing the "Expectation of Life" or "Mean After-Lifetime" of persons aged* 10, 20, 30, *etc., according to the under-mentioned Mortality Tables.*

Age.	Northampton, 1780.	Carlisle, 1815.	Equitable (Davies), 1825.	Equitable (Morgan), 1834.	Seventeen Offices' Experience, 1843.	English, No. 3 (Males), 1864.	Institute of Actuaries, H^M, 1869.
10	39·78	48·82	48·83	48·32	48·36	47·05	50·29
20	33·43	41·46	41·06	41·37	41·49	39·48	42·06
30	28·27	34·34	33·98	34·53	34·43	32·76	34·68
40	23·08	27·61	27·40	27·40	27·28	26·06	27·40
50	17·99	21·11	20·83	20·36	20·18	19·54	20·31
60	13·21	14·34	15·06	13·91	13·77	13·53	13·83
70	8·60	9·18	9·84	8·70	8·54	8·45	8·50
80	4·75	5·51	5·38	4·75	4·78	4·93	4·72
90	2·41	3·28	2·65	2·56	2·11	2·84	2·36

Having given this table for the purpose of comparing in a general way the characteristics of the several mortality tables to which it relates, it is right we should say, in order to avoid misconception, that the "expectation of life" does not enter into calculations for determining the value of sums dependent on human life, or for ascertaining the premiums required for life assurances. The nature of these latter calculations will be explained presently.

As a specimen of a mortality table deduced from actual observation of assured lives, we give in full the last of the tables from which the foregoing particulars are deduced, viz.:—

III.—*The H^M Table of the Institute of Actuaries.*

Age. x	No. Living. l_x	Decrement. d_x	Age. x	No. Living. l_x	Decrement. d_x	Age. x	No. Living. l_x	Decrement. d_x

Principles of calculation.

In order to show the method of calculating assurance premiums, we shall first suppose the premiums to be payable in one sum, and shall employ an illustration founded on the above table. We learn from the table that, of 96,223 persons living at the age of 20, 609 will die before reaching the age of 21; of the 95,614 persons remaining alive at the latter age, 643 will die before reaching the age of 22; and so on. Let it be supposed that 96,223 persons of the age of 20 are desirous to have their lives assured, each for the sum of £1 to be paid at the end of the year in which he shall happen to die; and let it be further assumed that the H^M table represents correctly the number of deaths that will occur among these 96,223 persons in each successive year, until the last of them dies between the ages of 97 and 98. According to the hypothesis, 609 payments of £1 each will fall to be made at the end of the first year, 643 at the end of the second, 650 at the end of the third, and so on until finally 9 payments fall to be made at the end of the seventy-eighth year. In order, therefore, to ascertain the "present value" of the whole 96,223 payments to be made after the decease of the persons whose lives are to be assured, we must find the value of £609 due one year hence, £643 due two years hence, £650 due three years hence, and so on to the last payments. The sum of all these values will be the total value required. Suppose the interest of money to be 3 per cent. per annum. Then (as explained in the article Annuities) the value of 1 to be paid at the end of one year is $\frac{1}{1·03}$; of 1 to be paid at the end of two years $\frac{1}{1·03^2}$; and so on. Consequently the total value of the supposed assurances will be the sum of the following terms:—

$$\text{Value of first year's payments } £609 \times \frac{1}{1·03} = £591·26$$

$$\text{“ second “ “ } 643 \times \frac{1}{1·03^2} = 606·09$$

$$\text{“ third “ “ } 650 \times \frac{1}{1·03^3} = 594·84$$

$$\text{etc.} \qquad = \text{etc.}$$

The sum of all the terms in this series is £31,644.

We have thus found that £31,644 is the present value of 96,223 assurances of £1 each on as many lives, of the same age 20, according to the H^M mortality table, reckoning interest at 3 per cent. It follows that, if all these persons are to contribute at the same rate for their several assurances, the share payable by each—or the single premium for an assurance of £1 on each life—will be £31,644 ÷ 96,223, or £·32886. If twice the number of persons were to be assured, there would be just double the number of claims to satisfy at the close of each year, and the contribution payable by each person would remain the same; and so in proportion for any smaller or larger number of persons. We conclude, therefore, that the single premium at age 20 for a whole-term assurance of £1 according to the $\mathrm{H^M}$ mortality table, reckoning interest at 3 per cent., is £·32886, or 6s. 7d.

Passing from numerical illustration to general symbols, the process displayed above may be stated as follows. The number of persons living at any given age (x) is represented[1] by the symbol l_x, and the number dying in the next year (that is, between the ages of x and $x+1$) by d_x, which is the equivalent of $l_x - l_{x+1}$. Hence the number of claims to be made at the end of successive years in respect of l_x assurances of 1 each, effected at the age of x, is represented by the series

$$d_x,\ d_{x+1},\ d_{x+2}\ \ldots\ldots\ d_{x+z},$$

where z is the difference between x and the highest age completed by any of the lives in the mortality table. The sum of all the terms in this series is of course l_x, since every person living at age x must die at one time or another within the period embraced in the table. If money made no interest, l_x would be the present value of all the assurances, and the premium payable by each person would be $l_x \div l_x$, or 1. To allow for the operation of interest, it is necessary to discount the several yearly payments for the periods during which they are respectively deferred. The series representing the present value of all the assurances thus becomes

$$vd_x + v^2d_{x+1} + v^3d_{x+2} + \ldots\ldots + v^{z+1}d_{x+z},$$

where $v = \dfrac{1}{1+i}$,—i being the interest of 1 for a year. Hence the premium payable by each of the l_x individuals is

$$\frac{vd_x + v^2d_{x+1} + v^3d_{x+2} + \ldots\ldots + v^{z+1}d_{x+z}}{l_x},$$

which is usually represented by the symbol A_x.

The same result may be arrived at by a process of reasoning based on the doctrine of probabilities. Since out of l_x persons alive at the age of x, and all (as we must suppose) equally exposed to the risk of death, d_x will die before completing another year of age, the chance that any one in particular of those l_x persons will die within the first year is as d_x to l_x. Similarly the chance of any particular person dying within the second year is as d_{x+1} to l_x; within the third year as d_{x+2} to l_x; and within the nth year as d_{x+n-1} to l_x. In any particular case, therefore, the probabilities of the sum assured becoming payable at the end of the first, second, third, nth years, are $\dfrac{d_x}{l_x}$, $\dfrac{d_{x+1}}{l_x}$, $\dfrac{d_{x+2}}{l_x}$, $\dfrac{d_{x+n-1}}{l_x}$, respectively; and the present value of the expectation of receiving 1 at the end of any year as the nth, is $v^n\dfrac{d_{x+n-1}}{l_x}$. Hence the value of 1 to be paid at the end of the year in which death occurs is the sum of all the terms in the series

$$v\frac{d_x}{l_x} + v^2\frac{d_{x+1}}{l_x} + v^3\frac{d_{x+2}}{l_x} + \ldots\ldots + v^{z+1}\frac{d_{x+z}}{l_x},$$

an expression which is identical with that given above.

Commutation method.

Reverting to the previous expression, it will be seen that by multiplying both numerator and denominator by the same quantity v^x we obtain, without altering the value of the formula,

$$\frac{v^{x+1}d_x + v^{x+2}d_{x+1} + v^{x+3}d_{x+2} + \ldots\ldots + v^{x+z+1}d_{x+z}}{v^xl_x}.$$

In this new expression the denominator is the product known as D_x in the commutation method (see again the article ANNUITIES); and the successive terms in the numerator are of the general form $v^{n+1}d_n$. This latter product is called C_n; so that the whole expression may be written

$$\frac{\mathrm{C}_x + \mathrm{C}_{x+1} + \mathrm{C}_{x+2} + \ldots\ldots + \mathrm{C}_{x+z}}{\mathrm{D}_x}.$$

In a commutation table the sum of C_x, C_{x+1}, C_{x+2}, ... C_{x+z} is placed in a column headed M_x; so that the single premium for an assurance payable after the death of a person aged x is $\dfrac{\mathrm{M}_x}{\mathrm{D}_x}$.

The single premium for an assurance on the same life "deferred" for m years—that is, to be payable only if death should occur after that period—is $\dfrac{\mathrm{M}_{x+m}}{\mathrm{D}_x}$ which is equivalent to

$$\frac{\mathrm{C}_{x+m} + \mathrm{C}_{x+m+1} + \ldots\ldots + \mathrm{C}_{x+z}}{\mathrm{D}_x},$$

and hence to

$$\frac{v^{m+1}d_{x+m} + v^{m+2}d_{x+m+1} + \ldots\ldots + v^{x+z+1}d_{x+z}}{l_x}.$$

By subtraction, the single premium for a "temporary" assurance for m years on the same life is $\dfrac{\mathrm{M}_x - \mathrm{M}_{x+m}}{\mathrm{D}_x}$, which is equivalent to

$$\frac{\mathrm{C}_x + \mathrm{C}_{x+1} + \ldots\ldots + \mathrm{C}_{x+m-1}}{\mathrm{D}_x},$$

and hence to

$$\frac{vd_x + v^2d_{x+1} + \ldots\ldots + v^md_{x+m-1}}{l_x}.$$

A column R is sometimes inserted in commutation tables to facilitate calculations relating to "increasing" assurances. R_x is the sum of the terms M_x, M_{x+1}, ... M_{x+z}; so that $\dfrac{\mathrm{R}_x}{\mathrm{D}_x}$ is the value of an assurance the amount of which shall be 1 if the life fails during the first year, 2 if during the second year, 3 if during the third year, and so on.

Formulæ in terms of annuity-values.

When the value of any immediate annuity, calculated at a given rate of interest, is known, the value of a sum payable one year after the last instalment of the annuity may be readily deduced from it. The value of any deferred payment is the difference between the sum to be ultimately paid and the discount for the period during which it is deferred. Let a be the value of an annuity of 1 at the rate of interest i, and let it be required to find the value of 1 due at the end of the year following the last payment of the annuity. The discount of 1 for one year at the rate of interest i is $\dfrac{i}{1+i} = 1 - v$; and the present value of such annual discount (payable in advance) for the whole period covered by the annuity and one year more is $(1-v)\ (1+a)$. Hence the value of the deferred payment of 1 is $1-(1-v)\ (1+a)$. Putting a_x for the value of an annuity on a life aged x, we have for the present value of a whole-term assurance on a life of that age $1-(1-v)\ (1+a_x)$.

The agreement of this result with those formerly deduced from the numbers dying in each year may be seen by substituting for d_x, d_{x+1}, etc., their equivalents $(l_x - l_{x+1})$, $(l_{x+1} - l_{x+2})$, etc., when the foregoing expression

$$\frac{vd_x + v^2d_{x+1} + \ldots\ldots + v^{z+1}d_{x+z}}{l_x}$$

becomes

$$\frac{v(l_x - l_{x+1}) + v^2(l_{x+1} - l_{x+2}) + \ldots\ldots + v^{z+1}(l_{x+z} - 0)}{l_x}$$

$$= \frac{vl_x + v^2l_{x+1} + \ldots\ldots + v^{z+1}l_{x+z}}{l_x}$$

$$- \frac{vl_{x+1} + v^2l_{x+2} + \ldots\ldots + v^zl_{x+z}}{l_x}$$

$= v(1+a_x) - a_x$; as will be seen from the article ANNUITIES. By a simple transposition this expression takes the form $v-(1-v)a_x$; which in its turn becomes $1-(1-v)(1+a_x)$.

Annual premiums.

Assurances, as formerly mentioned, are usually paid for by *annual* contributions or premiums, continuing either during the whole subsistence of the assurance or during a limited period only. The annual premium for an assurance is deduced as follows. Since the present value of all the annual payments must be equal to the single premium, and since premiums are always payable in advance, we have (putting P for the annual premium required) $\mathrm{P}(1+a) = \mathrm{A}$; whence $\mathrm{P} = \dfrac{\mathrm{A}}{1+a}$. In this expression A may represent the single premium for any benefit whatsoever, whether depending on single or joint lives, or on any other description of status; and $(1+a)$ may represent the value, in any such case, of an annuity payable in advance during the period over which the payment of premiums is to extend. The annual premium, payable during the whole of life, for a whole-term assurance on a life aged x is

$$\frac{1-(1-v)(1+a_x)}{1+a_x} = \frac{1}{1+a_x} - (1-v);$$

---

[1] The notation employed in this article is that recommended by the Institute of Actuaries in an appendix to their tables, published in 1872. Of the alternative forms l_{x+n} and ${}^nl_x$, to express the number living at age $x+n$, we prefer the former as being less liable to create confusion when used in connection with other symbols.

or
$$\frac{v(1+a_x)-a_x}{1+a_x}=v-\frac{a_x}{1+a_x};$$

or it may be expressed in a variety of other ways by substituting different equivalents of the single premium and the annuity.

When the premium is to be payable for m years only, its amount is expressed by $\frac{A}{1+|_{m-1}a}$, where the symbol $|_{m-1}a$ represents the value of a temporary annuity for $m-1$ years; and $1+|_{m-1}a$ is therefore the value of an annuity for m years payable in advance.

When the premium for the first m years is to be $\frac{1}{r}$th of that for the remainder of life, the ultimate annual payment is found by the expression $\frac{A}{\frac{1}{r}(1+|_{m-1}a)+{}_{m-1|}a}$ where $_{m-1|}a$ is the value of an annuity deferred for $m-1$ years, and therefore of an annuity deferred for m years, but payable in advance.

By the commutation method the annual whole-life premium is $\frac{M_x}{D_x}\div\frac{N_{x-1}}{D_x}=\frac{M_x}{N_{x-1}}$. The premium limited to m annual payments, for a whole-term assurance, is
$$\frac{M_x}{N_{x-1}-N_{x+m-1}}.$$
The premium payable after m years, when the payment during that period is $\frac{1}{r}$th of the ultimate annual payment,

is
$$\frac{M_x}{\frac{1}{r}(N_{x-1}-N_{x+m-1})+N_{x+m-1}}, \quad \text{or} \quad \frac{rM_x}{N_{x-1}+(r-1)N_{x+m-1}}.$$

We do not propose to enter further on the investigation of formulæ for the calculation of premiums for the various descriptions of life assurances. These will be found in the works of Milne, Baily, Jones, and other authors who have treated of the subject of life contingencies. The student will find a very clear exposition of the nature and modes of calculation of the more ordinary kinds of premiums in a paper by Mr. James Meikle, *The Rationale of Life Assurance Premiums*, reprinted by the Actuarial Society of Edinburgh in 1879.

Practical methods.

In the practical calculation of life assurance premiums various devices have been suggested for shortening labor and ensuring accuracy. Mr. Peter Gray's method of calculation, by means of logarithmic tables on the plan originated by Gauss, may be specially mentioned. His *Tables and Formulæ*, in which this method is explained, is a work of great value to the student of life contingencies.

When the requisite annuity-values are available, the tables of assurance premiums constructed by Mr. William Orchard afford great facilities, either in forming scales of premiums or in isolated calculations. The foregoing expressions for the single premium in terms of the corresponding values of annuities are of such a character as to be applicable to a great variety of cases—to nearly every case, in fact, where the risk of the assurance is to be entered on immediately, and the sum assured is to be payable at the end of the year following the last payment of the annuity embraced in the formulæ. In like manner the formulæ for the annual premium, $\frac{1}{1+a}-(1-v)$, and its equivalents are applicable in all such cases, but only when the premium is to be payable during the whole continuance of the assurance, so that in the expression
$$\frac{1-(1-v)(1+a)}{1+a}$$
the annuity value a in the denominator corresponds with that in the numerator. Mr. Orchard has tabulated the values of $v-(1-v)a$ and $\frac{1}{1+a}-(1-v)$ for all probable values of a, and for the several values of v corresponding to eight different rates of interest. By means of these tables, when the annuity-value corresponding to any required single or annual premium is known, the premium itself may be obtained by mere inspection. The tables may be employed with annuities derived from any table of mortality, and, as the various cases to which they apply are by far the most frequent in practice, they are found extremely useful by computers.

We have throughout supposed that the payment of the sum assured is to be made at the end of the year in which death occurs. This supposition accords with the theory of annual mortality and annual conversion of interest into capital, upon which the usual system of calculation is based. It also agrees very nearly with fact when the sums assured are payable six months after death; for, if it be supposed that the deaths occurring within each year of age take place at equal intervals of time, or that they occur in equal numbers in the first and second halves of each year respectively, the persons insured will, one with another, complete about half a year of age in the year when they die. When it is thought desirable to make allowance, in the calculation of premiums, for the circumstance of the sums assured being payable earlier than at the end of the year of death, that may be done by a simple modification of the usual formulæ. For example, $A(1+i)^{\frac{1}{2}}$ is an approximation sufficiently near for most purposes to the value of an assurance payable as soon as death occurs.

Continuous theory.

The more scientific methods of calculation developed by Mr. Woolhouse and others, and referred to in the article ANNUITIES, eliminate both the hypothesis of payments being due at the end of the year and that of a uniform distribution of each year's deaths, neither of which is strictly admissible. The lives assured, instead of being regarded as subject to successive yearly decrements, are considered to be diminishing in number continuously; and in like manner interest, instead of being payable annually, is supposed to be growing due from moment to moment. The methods referred to afford great facilities for the solution of various problems which can only be solved approximately, or with extreme labor, by the usual modes of computation, but they are not employed in the ordinary calculations of assurance offices.

"Net premiums" and "office premiums."

The premiums obtained by calculation from the fundamental data of interest and mortality are called "net" or "pure" premiums. In calculating the premiums to be charged by an assurance office, it is to be borne in mind that, while fluctuations will undoubtedly occur in the rates of mortality prevailing at different times among the lives assured, and in the rates of interest realized on the invested funds, the terms on which assurances are undertaken are not subject to variation at the will of the office in order to meet such fluctuations. The office must hold itself absolutely responsible for the fulfilment of its part of the contract, but the premiums cannot be increased beyond the amount fixed at the outset. Hence it is obviously necessary that the premiums should be on such a scale as to keep the office safe under all circumstances. Further, the premiums must contain a sufficient provision for the expenses necessarily incurred in carrying on business. Therefore the rates actually charged must be larger than those which would suffice if only a probable death-rate and a probable rate of interest had to be taken into account. In the earliest days of assurance it seems to have been the practice to make an addition for safety to the rates of premium deduced from the fundamental data, and certain payments were required as "entry-money" to help to meet expenses. Afterwards, when experience had shown that the tables of mortality then in use considerably overstated the death-rate likely to be experienced, the addition made to the premiums was removed, but the offices continued to use tables giving high death-rates in combination with a rate of interest well within that which might safely be expected. With the introduction, however, of mortality tables which approached more closely the death-rates among assured lives, there revived the practice of making an addition to the "pure" premiums, in order to provide for expenses, for fluctuations in the death-rate, and for other contingencies. This addition is called the "loading" or "margin," and the premiums which include it are called "office premiums," as being those which enter into the contract between the office and the assured.

"Loading" or "margin."

Few if any of the older assurance offices continue to base their estimates of liability on the tables which were originally employed in the construction of their scales of premium; but many of them still charge the same rates as formerly, or at all events rates which have not been constructed from the tables of mortality now in use. Hence the terms "loading" and "margin" have come to bear a somewhat extended meaning. They are now used to designate the difference between the premiums payable by the assured and the net premiums deduced from any table that may be employed for the time.

There have been various theories as to the proper method of loading premiums. The plan most commonly employed at first was that of adding a constant percentage of the net premiums at all ages. Some actuaries objected to this method, holding it to be inequitable as between old and young lives, and proposed in its stead the addition of an equal sum for every age (that is, in effect, a constant percentage of the sum assured) as more in accordance with the object in view. By others a combination of these two plans was preferred. The premiums were loaded by a percentage for "profit" and contingencies, and a constant addition was made to cover the expenses of management. More recently other methods have been proposed, and it has been specially insisted on that the "loading" should be adjusted so as to give due weight to the fact that by far the larger proportion of expense is usually connected with the first year's premium; but most of the scales of premiums now in use by assurance offices have been arrived at by one or other of the methods of loading mentioned above.

The rates of the Northampton Table, at 3 per cent. interest, furnish an example of a scale of net rates used as office premiums, without any specific addition by way of "loading." These are shown in the following table. As an example of a scale of office premiums formed by loading with a constant percentage, we give that obtained by adding 25 per cent. to the net rates of the Carlisle table, reckoning interest at 3 per cent. It will be seen that, owing to the lower death rate shown by that table, the premiums even with the addition mentioned are lower than those of the Northampton Table up to age fifty. After that age the loaded Carlisle premiums are higher than the Northampton pure premiums, but still the Carlisle rates without loading are lower than the Northampton rates. For the sake of further illustration we give the net premiums deduced from the healthy males table (H^M) of the Institute of Actuaries at the same rate of interest; and in a separate column is shown what percentage of "loading," on a comparison with those premiums, is contained in the Carlisle rates with their 25 per cent. addition. The premiums are those required for the assurance of £100 for the whole term of life.

Age. (1)	Northampton, 3 per cent. rates, net. (2)	Carlisle 3 per cent. rates, with 25 per cent. added. (3)	H^M 3 per cent. rates, without loading. (4)	Percentage by which col. (3) exceeds col. (4). (5)
15	£1 18 7	£1 13 2	£1 4 6	35·37

Assurance offices.

Constitution of Offices.—The nature of life assurance is such as to render impracticable its successful prosecution as a matter of individual or private enterprise. To secure a sufficiently uniform operation of the laws of average, the transactions must be carried out on a scale quite incompatible with the sufficiency of private credit for their fulfilment; while the indefinite and lengthened periods over which the engagements extend also mark them out as beyond the reach of individual responsibility.

Mutual. Proprietary.

Accordingly, with the limited exception of the insurance scheme of the Government, the business in the United Kingdom may be said to be entirely in the hands of public companies or societies. These bodies have been of three kinds—(1) the purely *mutual* offices, in which the assured themselves constitute the society; (2) *proprietary* offices, as they once existed, being joint-stock companies which carried on the business of assurance for the benefit of the shareholders, among whom were divided the whole "profits" or "surplus" arising from the contributions of the assured; and (3) the *mixed* offices, possessed of a share capital, but dividing among their assured a proportion (generally from two-thirds to nine-tenths) of the "profits" realized. In the present day there are but two kinds of offices, *mutual* and *mixed*, the proprietary companies either having disappeared or having adopted the plan of sharing profits with the policy-holders.

Mixed.

Into the relative merits of the two classes of offices it is not our purpose to enter. The mutual offices take their stand on the advantage to the assured of sharing the whole profits among themselves, while the mixed offices point to certain features of their system which tend to neutralize the apparent disadvantage of the shareholders taking a portion of the surplus. We believe it will be found that the fact of an office belonging to one class or the other does not of itself afford a presumption either for or against its being an advantageous office to assure in. The comparative advantages of different companies must be sought out by a closer scrutiny than a mere reference to this distinction in the nature of their constitution.

Most assurances are effected on the plan of participating in profits. In both mutual and mixed offices, however, there is generally a class of policy-holders who do not share in the profits, but who, requiring only a guarantee of a fixed sum on the happening of the contingency mentioned in their policies, effect their assurances at a reduced rate of premium calculated to cover fully the risk and expenses of business.

Selection of lives.

Selection of Lives.—It is well known that assurance companies exercise a selection among the lives proposed for assurance, admitting some on the ordinary terms and surcharging or rejecting others whose prospects of longevity appear to be below the average. The necessity for this has been sometimes called in question. Why, it has been asked, should the offices inquire so scrupulously into the state of health of those who offer themselves, if the mortality tables on which the premiums are based exhibit the death-rate among a number of persons in all the degrees of health and sickness? The answer is that without such selection on their part the offices could not reckon on the lives assured being as a body equal to those represented in the tables. It must be remembered that the inducement to become assured is not so great to the healthy and vigorous as it is to the weak and delicate, and if the offices were to open their doors to all comers, or were even to relax their vigilance in scrutinizing the applications made to them, they would inevitably admit an undue proportion of the latter class, and thus expose themselves to greater hazards than those provided for in their tables. Moreover, since the assured have a direct interest in the surplus remaining of their premiums, after providing the cost of the assurances, the admission of all lives on equal terms would be an injustice to those possessing a full measure of health. They would practically be called upon to contribute more than their own cases required, in order to provide a fund sufficient to pay the sums assured on lives having inferior prospects of longevity.

Means of selection.

The means of selection employed by assurance offices are also well known. Each applicant is required to furnish information as to his own health and habits of life, and some particulars as to his family history, and he undergoes an examination by a medical man named by the office. In former days this examination was not always required, nor does it appear that the same attention was paid as now to the question of hereditary tendencies to disease; and yet, judging from the experience of the older offices, the precautions observed in those days seem to have been not without considerable effect. Unquestionably, however, the improvements which growing experience and the advance of medical science have brought to bear upon the means of selection have had an important influence in increasing its efficacy, although possibly they may have done little more than to defend the offices against a greater risk of the introduction of questionable lives. It is now well understood that hereditary tendencies have a marked effect in determining the chances of longevity of individuals; the degree of importance to be attached to particular deviations from health is better known than formerly; while the increased prevalence of assurance has led to a better appreciation among medical men of the duties required of them in the examination of proposers. In some of the medical schools special attention is now directed to the subject. Several excellent works on medical selection have appeared, one of the most recent in England being that of Dr. Sieveking of London.

Its effects.

It may readily be supposed that selection has an important influence in determining the rates of mortality among assured lives. The extent and nature of this influence have formed a very fruitful and interesting subject of inquiry. So early as 1776 an investigation of the affairs of the Equitable Society revealed that the death-rate among the members had been much lower than that anticipated in the tables on which the premiums were based. Similar results appeared at the subsequent investigations of W. Morgan and A. Morgan, who were successively actuaries of the society; and in many other collections of the statistics of individual offices—those by Galloway of the Amicable (1841), Jellicoe of the Eagle (1854), Spens of the Scottish Amicable (1862), for example—the mortality among assured lives has been exhibited in comparison with the death-rates shown by the mortality tables in common use. Comparisons of this kind may be drawn from the tables on a preceding page. These do not, however, afford the means of observing what is a very marked peculiarity of the mortality experience of assurance companies, namely, the varying death-rates at different periods in the duration of assurances. Mr. Spens devoted considerable attention to this subject, but it had been previously investigated in connection with the statistics of the seventeen offices to 1843 already referred to. These statistics were analyzed with this object by Mr. E. J. Farren, who pointed out the extremely light mortality experienced during the first year of each assurance. A more exhaustive analysis is given by Mr. Higham, in a paper "On the Value of Selection as exercised by the Policy-holder," contributed to the *Assurance Magazine*[1] (vol. i. p. 179). Mr. Higham traces the lives from their first year of assurance down to the time of their passing from observation, by death or otherwise, and shows that the mortality, light at first in consequence of the initial selection exercised by the offices, gradually increases until it becomes greater than that prevailing among the general population. This latter result he attributes to the selection which the assured exercise against the companies by dropping policies on healthy lives and retaining those on lives which have become bad or doubtful. A still more complete investigation of the subject of selection has been made by Mr. Sprague (*Assur. Mag.*, xiv. 328), who shows that the deterioration noticed by Mr. Higham attains its maximum some time before the lives pass from observation, and is ultimately reversed after the full effect produced by the withdrawal of good lives has exhausted itself. Mr. Sprague's statistics are taken from the Twenty Offices' Experience to 1863. In the collection of that experience the effects of the two kinds of selection that have now been referred to—selection by the assurance offices and selection against the offices—were kept in view as a subject to be investigated; and in the preface to the tables published in 1869 the subject is considered at some length, and several interesting tables are devoted to its illustration. The following figures, extracted from one of those tables, show the rates of mortality at different quinquennial periods of life among the "healthy lives, male and female,"—dividing the lives into groups according to the duration of their assurances.

Counter selection.

Age. (1)	Annual Mortality per cent. in periods of Assurance.				
	Under five years. (2)	Five years and Upwards. (3)	Under ten years. (4)	Ten years and Upwards. (5)	Total. (6)
20 to 24	·67	·90	·71	·64	·71
25 " 29	·66	1·00	·73	·92	·73
30 " 34	·76	·97	·83	1·00	·85
35 " 39	·83	1·10	·93	1·17	·97
40 " 44	·91	1·19	1·00	1·28	1·09
45 " 49	1·17	1·44	1·25	1·52	1·36
50 " 54	1·28	1·85	1·52	1·90	1·72
55 " 59	1·81	2·47	2·10	2·52	2·35
60 " 64	2·71	3·50	3·05	3·55	3·38
65 " 69	3·63	5·06	4·35	5·11	4·90
70 " 74	5·51	7·35	6·51	7·40	7·23

A prominent feature of this table is the divergence of the figures in column 3 from those in column 2, and on the other hand the comparatively close agreement of the figures in column 3 with those in column 5. This seems to indicate that among lives which have been less than five years assured the rate of mortality is materially lower than that prevailing among lives of similar ages who have been assured for longer periods, but that after the first five years the causes which bring about this lessening of the rate of mortality have in great measure ceased to operate. It was this peculiarity of the statistics that led to the construction of the $\mathrm{H}^{\mathrm{M}(5)}$ table,—the first five years of assurance being regarded as marking, although not in any strict or absolute sense, a distinct period in the value of assured life, after which "for all practical purposes the benefit of selection may perhaps be said to be lost." Mr. Sprague has since pointed out that this distinction is not altogether satisfactory, and he has sought by the construction of a series of "Select Mortality Tables" for separate ages at entry (*Ass. Mag.* xx. 95 and xxi. 229) to supply a more exact basis of calculation than the H^{M} and $\mathrm{H}^{\mathrm{M}(5)}$ tables afford.

Besides its influence upon the rates of mortality, selection has also a very noticeable effect in regard to the causes of death among the assured. Diseases to which a predisposition may be inferred from family or personal history, or which admit of detection in an early stage by careful medical scrutiny, are less frequent among this selected class of lives than among the general population, while, on the other hand, assured persons seem to be more liable than others to particular forms of disease. This interesting subject is dealt with by Mr. Meikle in his *Observations*, formerly referred to; and it is also illustrated in numerous reports on the experience of different assurance companies by their medical officers.

Valuation of liabilities.

Valuations.—The business of life assurance being founded on well-ascertained natural laws, and on principles of finance which in their broad aspect are of the simplest description, there exists no necessity for frequent close scrutiny of the affairs of an insurance office, in so far as the maintenance of a mere standard of solvency is concerned. We have seen that the premiums charged for assurances are based on certain assumptions in regard to (1) the rate of mortality to be experienced. (2) the rate of interest to be earned by the office on its funds, and (3) the proportion of the premiums to be absorbed in expenses and in providing against unforeseen contingencies. If these assumptions are reasonably safe, an assurance office proceeding upon them may be confidently regarded as solvent so long as there is no conspicuously unfavorable deviation from what has been anticipated and provided for, and so long as the funds are not impaired by imprudent investments or otherwise. The ascertainment and division of profits, however, require that the affairs should be looked into periodically; but the fluctuations to which the surplus funds are liable within limited periods of time, from variations of the death-rate and other causes, are generally regarded as furnishing a sufficient reason why such investigations should not take place too frequently. Accordingly in most offices the division of profits takes place only at stated intervals of years,—usually five or seven years,—when a complete survey is taken of the whole engagements present and future, and of the funds available to meet these. The mode in which the liability of an office under its current policies is estimated requires explanation.

---

[1] The *Assurance Magazine*—or, as it is now called, the *Journal of the Institute of Actuaries*—continues to be, as it has been for many years, the principal medium of publication for what is new and important in actuarial science. Under the auspices of the Institute of Actuaries, a text-book is in preparation which, when completed, will no doubt bring within a convenient compass much that is now scattered throughout the *Journal* and other works. In the meantime the student will find it indispensable to make himself acquainted with many of the valuable papers contained in the *Assurance Magazine*.

Nature of reserve values.

All statistical observations on the duration of human life point to the conclusion that, after the period of extreme youth is past, the death-rate among any given body of persons increases gradually with advancing age. If, therefore, assurance premiums were annually adjusted according to the chances of death corresponding to the current age of the assured, their amount would be at first smaller, but ultimately larger, than the uniform annual payment required to assure a given sum whenever death may occur. This is illustrated by the following figures, calculated from the H^M mortality table at 3 per cent. interest. In column 2 is the uniform annual premium at age thirty for a whole-term assurance of £100. In column 3 are shown the premiums which would be required at the successive ages stated in column 1 to assure £100 in the event of death taking place within a year. Column 4 shows the differences between the figures in column 2 and those in column 3.

Age, $30+n$. (1)	P_{30}. (2)	$_{\mid 1}A_{30+n}$. (3)	$P_{30}-{}_{\mid 1}A_{30+n}$. (4)
30	£1·880	£·750	+£1·130
31	1·880	·769	+ 1·111
32	1·880	·787	+ 1·093
…	……	………	………
…	……	………	………
…	……	………	………
53	1·880	1·806	+ ·074
54	1·880	1·916	— ·036
55	1·880	2·042	— ·162
…	……	………	………
…	……	………	………
…	……	………	………
95	1·880	61·848	—59·968
96	1·880	79·265	—77·385
97	1·880	97·087	—95·207

From this table it appears that if a number of persons effect, at the age of thirty, whole-term assurances on their lives by annual premiums which are to remain of uniform amount during the subsistence of the assurances, each of them pays for the first year £1·130 more than is required for the risk of that year. The second year the premiums are each £1·111 in excess of that year's risk. The third year the excess is only £1·093, and so it diminishes from year to year. By the time the individuals who survive have reached the age of fifty-four, their uniform annual premiums are no longer sufficient for the risk of the following year; and this annual deficiency goes on increasing until at the extreme age in the table it amounts to £95·207, the difference between the uniform annual premium (£1·880) and the present value (£97·087) of £100 certain to be paid at the end of a year. Now, since the uniform annual premiums are just sufficient to provide for the ultimate payment of the sums assured, it is obvious that the deficiencies of later years must be made up by the excess of the earlier payments; and, in order that the assurance office may be in a position to meet its engagements, these surplus payments must be kept in hand and accumulated at interest until they are required for the purpose indicated. It is, in effect, the accumulated excess here spoken of which constitutes the measure of the company's liability under its policies, or the sum which it ought to have in hand to be able to meet its engagements. In the individual case this sum is usually called the "reserve value" of a policy.

In another view the reserve value of a policy is the difference between the present value of the engagement undertaken by the office and the present value of the premiums to be paid in future by the assured. This view may be regarded as the counterpart of the other. For practical purposes it is to be preferred, as it is independent of the variations of past experience, and requires only that a rate of mortality and a rate of interest be assumed for the future.

According to it, the reserve value ($_nV_x$) of a policy for the sum of 1, effected at age x, and which has been in force for n years—the $(n+1)$th premium being just due and unpaid—may be expressed thus, in symbols with which we have already become familiar.

$$_nV_x = A_{x+n} - P_x(1 + a_{x+n}) \quad . \quad . \quad . \quad . \quad . \quad (1).$$

If we substitute for A_{x+n} its equivalent $P_{x+n}(1 + a_{x+n})$ this expression becomes

$$_nV_x = (P_{x+n} - P_x)(1 + a_{x+n}) \quad . \quad . \quad . \quad . \quad . \quad (2);$$

whence we see that the sum to be reserved under a policy after any number of years arises from the difference between the premium actually payable and the premium which would be required to assure the life afresh at the increased age attained. By substituting for P_{x+n} and P_x their equivalents $\frac{1}{1+a_{x+n}} - (1-v)$ and $\frac{1}{1+a_x} - (1-v)$, we obtain another useful form of the expression,

$$V_x = 1 - \frac{1 + a_{x+n}}{1 + a_x} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

$$= \frac{a_x - a_{x+n}}{1 + a_x} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Net liability.

The preceding formulæ indicate clearly the nature of the calculations by which an assurance office is able to ascertain the amount of funds which ought to be kept in hand to provide for the liabilities to the assured. In cases other than whole-term assurances by uniform annual premiums, the formulæ are subject to appropriate modifications. When there are bonus additions to the sums assured, the value of these must be added, so that by the foregoing formula (1), for example, the value of a policy for 1 with bonus additions B is $(1+B)A_{x+n} - P(1+a_{x+n})$. But the general principles of calculation are the same in all cases. The present value of the whole sums undertaken to be paid by the office is ascertained on the one hand, and on the other hand the present value of the premiums to be received in future from the assured. The difference between these (due provision being made for expenses and contingencies, as afterwards explained) represents the "net liability" of the office. Otherwise, the net liability is arrived at by calculating separately the value of each policy by an adaptation of one or other of the above formulæ. In either case, an adjustment of the annuity-values is made, in order to adapt these to the actual conditions of a valuation, when the next premiums on the various policies are not actually due, but are to become due at various intervals throughout the succeeding year.

Provision for expenses, etc.

So far in regard to the provision for payment of the sums contained in the policies, with their additions. We now come to the provision for future expenses, and for contingencies not embraced in the ordinary calculations. In what is called the "net-premium" method of valuation, this provision is made by throwing off the whole "loading" in estimating the value of the premiums to be received. That is to say, the premiums valued, in order to be set off against the value of the sums engaged to be paid by the office, are not the whole premiums actually receivable, but the net or pure premiums derived from the table employed in the valuation. The practical effect of this is that the amount brought out as the net liability of the office is sufficient, together with the net-premium portion of its future receipts from policy-holders, to meet the sums assured under its policies as they mature, thus leaving free the remaining portion—the margin or loading—of each year's premium income to meet expenses and any extra demands. When the margin thus left proves more than sufficient for those purposes, as under ordinary circumstances it always ought to do, the excess falls year by year into the surplus funds of the office, to be dealt with as profit at the next periodical investigation.

Net-premium method.

There appears to be a decided preference among assurance companies for the net-premium method as that which on the whole is best suited for valuing the liabilities of an office transacting a profitable business at a moderate rate of expense, and making investigations with a view to ascertaining the amount of surplus divisible among its constituents. Under certain circumstances it may be advisable to depart from a strict application of the characteristic feature of that method, but it must always be borne in mind that any encroachment made upon the "margin" in valuing the premiums is, so far, an anticipation of future profits. Any such encroachment is indeed inadmissible, unless the margin is at least more than sufficient to provide for future expenses, and in any case care must be taken to guard against what are called "negative values." These arise when the valuation of the future premiums is greater than the valuation of the sums engaged to be paid by the office, or when in the expression $(P_{x+n}-P_x)(1+a_{x+n})$ the value of P_x is increased so as to be greater than that of P_{x+n}. It is evident that any valuation which includes "negative values" must be misleading, as policies are thereby treated as assets instead of liabilities, and such fictitious assets may at any time be cut off by the assured electing to drop their policies.

Negative values.

In recognition of the fact that a large proportion of the first year's premiums is in most offices absorbed by the expense of obtaining new business, it has been proposed by some actuaries to treat the first premium in each case as applicable entirely to the risk and expenses of the first year. At a period of valuation the policies are to be dealt with as if effected a year after their actual date, and at the increased age then attained.

Another modification of the net-premium method has been advocated for valuing policies entitled to bonus additions. It consists in estimating the value of *future* bonuses (at an assumed rate) in addition to that of the sum assured and *existing* bonuses, and valuing on the other hand so much of the office premiums as would have been required to provide the sum assured and bonuses at the time of effecting the assurance. This tends to secure, to some extent, the maintenance of a tolerably steady rate of bonus.

Hypothetical method.

An essentially different method is employed by some offices, and is not without the support of actuaries whose judgment is entitled to every respect. It has been called the "hypothetical method." By it the office premiums are made the basis of valuation. Hypothetical annuity-values, smaller than those which would be employed in the net-premium method, are deduced from the office premiums by means of the relation $P'=\frac{1}{1+a'}-(1-v)$, and the policies are valued according to the formula

$${}_nV'_x=(P'_{x+n}-P'_x)(1+a'_{x+n}),$$

where P'_x and P'_{x+n} are the office premiums at ages x and $x+n$ respectively, and a'_{x+n} is the hypothetical annuity value at the latter age. Mr. Sprague has shown (*Ass. Mag.* xi. 90) that the policy-values obtained by this method will be greater or less than, or equal to, those of the net-premium method according as the "loading" is a constant percentage of the net premium or an equal addition to it at all ages, or of an intermediate character, its elements being so adjusted as to balance each other.

When the net-premium method is employed, it is important that the office premiums be not altogether left out of view, otherwise an imperfect idea will be formed as to the results of the valuation. Suppose two offices, in circumstances as nearly as possible similar, estimate their liabilities by the net-premium method upon the same data, but office A charges premiums which contain a margin of 20 per cent. above the net premiums, and office B charges premiums with a margin of 30 per cent. Then, in so far as regards their net liabilities (always supposing the sum set aside in each case to be that required by the valuation), the reserves of those offices will be of equal strength, and if nothing further were taken into account, they might be supposed to stand in the same financial position. But it is obvious that office B, which has a margin of income 50 per cent. greater than that of office A, is so much better able to bear any unusual strain in addition to the ordinary expenditure, and is likely to realize a larger surplus on its transactions. Hence it appears that in order to obtain an adequate view of the financial position of any office it is necessary to consider, not only the basis upon which its reserves are calculated, but also the proportion of "loading" or "margin" contained in its premiums, and set aside for future expenses and profits.

Effects of different data.

Valuations may be made on different data as to mortality and interest, and the resulting net liability will be greater or less according to the nature of these. Under any given table of mortality a valuation at a low rate of interest will produce a larger net liability—will require, that is to say, a higher reserve to be made by the office against its future engagements to the assured—than a valuation at a higher rate. The effect of different assumptions in regard to the rates of mortality cannot be expressed in similar terms. A table of mortality showing a high death-rate, and requiring, consequently, large assurance premiums, does not necessarily produce large reserve values. The contrary indeed may be the case, as with the Northampton Table, which requires larger premiums than the more modern tables, but gives on the whole smaller reserve values. The amount of the net liability depends, not on the absolute magnitude of the rates of mortality indicated by the table, but on the ratio in which these increase from age to age.

If the values deduced by the net-premium method from any two tables be compared, it will be seen that

$$V'_x >, =, \text{ or } < {}_nV_x$$

according as

$$1-\frac{1+a'_{x+n}}{1+a'_x} >, =, \text{ or } < 1-\frac{1+a_{x+n}}{1+a_x}$$

i.e., as

$$\frac{1+a_{x+n}}{1+a_x} >, =, \text{ or } < \frac{1+a'_{x+n}}{1+a'_x} \quad . \quad . \quad . \quad . \quad (1),$$

or as

$$\frac{1+a'_x}{1+a_x} >, =, \text{ or } < \frac{1+a'_{x+n}}{1+a_{x+n}} \quad . \quad . \quad . \quad . \quad (2);$$

where the accented symbols throughout refer to one table and the unaccented symbols to the other.

We have thus the means of ascertaining whether the policy-values of any table will be greater or less than, or equal to, those of another, either (1) by calculating for each table separately the ratios of the annuity-values at successive ages, and comparing the results, or (2) by calculating at successive ages the ratios of the annuity-values of one table to those of another, and observing whether these ratios decrease or increase with advancing age, or remain stationary throughout. The above relations will subsist whatever may be the differences in the data employed, and whether or not the annuity-values by the different tables are calculated at the same rate of interest. When the same rate of interest is employed, any divergence in the ratios of the annuity-values will of necessity be due to differences in the rates of mortality. This interesting subject is investigated by Mr. Meikle in a paper on *Policy Life-Lines*, one of the Actuarial Society's publications, and by Mr. Sprague in the *Assurance Magazine*, vol. xxi. p. 77.

The following table gives examples of the reserve values of policies for £100, calculated on the net-premium method by three different mortality tables, at a uniform rate of interest, 3 per cent.

Table Reserve Values.

Age at Entry.	Northampton.	Carlisle.	Institute of Actuaries H^M.
Duration of policy five years.			
20	£4·196	£4·534	£4·360
30	5·490	5·464	6·135
40	7·294	7·053	8·708
50	9·571	12·374	12·100
60	13·668	13·698	16·180
Duration of policy ten years.

40	31·998	36·660	38·183
50	42·438	46·914	48·601
60	55·637	53·315	57·792

Data employed by offices.

Something may be said here as to the data on which assurance companies make their valuations. The *rates of interest* assumed by different offices may be said to range between 3 and 4 per cent., being in most cases lower than 4. It is, however, in regard to the *tables of mortality* that the greatest diversity exists. The Northampton Table has, for valuation purposes, been all but discarded. The Carlisle Table has so far lost its ground, since the introduction of the more recent Experience Tables, as to be now used by only a minority of the offices as the chief basis of their calculations. The different tables based on the experience of the Equitable Society, the Seventeen Offices' Experience, and the English Life Tables have still some adherents, and (besides those offices which value by the "hypothetical method") a few companies employ tables constructed specially for their own use. But there is an evident tendency towards the general adoption of the Institute of Actuaries (twenty offices) Tables, which have been used by a large proportion of the companies in their latest valuations. Of these, the tables chiefly employed are H^M and $H^{M(5)}$, the latter being used by some offices in combination with the H^M pure premiums, in order to eliminate as far as possible the effects of selection. Mr. King (*Ass. Mag.*, xix. 381, and xx. 233) and Mr. Sprague (*Ass. Mag.*, xxi. 229, and xxii. 391) have shown the construction of tables which would give in a more direct and scientific way the result that is aimed at by using the combined H^M and $H^{M(5)}$ tables. Mr. King, to illustrate the results of his method, constructs a "model office," assuming a uniform annual influx of new business and a rate of discontinuance of policies based on the experience of the twenty offices which contributed their statistics to the formation of the Institute of Actuaries Tables, and he shows the comparative reserves required by such an office at the end of successive quinquennial periods, according to various mortality tables and at different rates of interest. As these illustrative tables afford an admirable means of comparing the results of valuing by different mortality tables, we give the following extracts. It must be borne in mind, however, in seeking to apply the figures in these tables to estimate the strength of the reserves maintained by particular offices, that the soundness of the estimate may be a good deal affected by circumstances. In particular the rates at which new business has come in and policies have been discontinued must be taken into account, and, as before stated, the amount of "margin" contained in the premiums must not be lost sight of. Moreover, the supposed liabilities do not include bonus additions, and the presence of these will of course modify any conclusions drawn from the tables.

Sources of profit.

Division of Surplus.—There are various sources from which a surplus of funds may arise in an assurance company:—(1) from the rate of interest actually earned being higher than that anticipated in the calculations; (2) from the death-rate among the assured being lower than that provided for by the mortality tables; (3) from the expenses and contingent outlay being less than the "loading" provided to meet them; and (4) from miscellaneous sources, such as profitable investments, the cancelment of policies, etc.

Supposing a valuation to have been made on sound data and by a proper method, and to have resulted in showing that the funds in hand exceed the liabilities, the surplus thus ascertained may be regarded as *profit*, and either its amount may be withdrawn from the assets of the office or the liabilities may be increased in a corresponding degree.

Bonuses.

Various methods are employed by assurance companies in distributing their surplus funds among the assured. In some offices the share or "bonus" falling to each policy-holder is paid to him in cash; in others it is applied in providing a reversionary sum which is added to the amount assured by the policy; in others it goes to reduce the annual contributions payable by the policy-holder. A method of more recent introduction is to apply the earlier bonuses on a policy to limit the term for which premiums may be payable, thus relieving the policy-holder of his annual payments after a certain period. Another method is to apply the bonuses towards making the sum assured payable in the lifetime of the policy-holder. The plan of reversionary bonus additions is most common, and when it is followed, the option is usually given of exchanging the bonuses for their value in cash or of having them applied in the reduction of premiums.

Not only are there different modes of applying surplus, but the basis on which it is divided among the assured also varies in different offices. In some the reversionary bonus is calculated as an equal percentage per annum of the sum assured, reckoning back either to the commencement of the policy in every case, or (more commonly) to the preceding division of profits. In others the rate is calculated, not only on the original sums assured, but also on previous bonus additions. In others the ratio of distribution is applied to the cash surplus, and the share allotted to each policy is dealt with in one or other of the ways above indicated. The following are some of the ratios employed by different offices in the allocation of profits:—(1) in proportion to the amount of premiums paid (with or without accumulated interest) since the last preceding valuation; (2) in proportion to the accumulated "loading" of the premiums so paid; (3) in proportion to the reserve values of the policies; (4) in proportion to the difference between the accumulated premiums and the reserve value of the policy in each case.

Some offices have a special system of dealing with surplus, reserving it for those policy-holders who survive the ordinary "expectation of life," or whose premiums paid, with accumulated interest, amount to the sums assured by their policies. This system is usually connected with specially low rates of premium.

The various bonus systems which have been mentioned yield different results to policy-holders of different ages, and whose assurances have been in force for longer or shorter periods. A person seeking to effect an assurance may exercise a wise discretion in selecting that office whose bonus system appears most advantageous, considering his own age and circumstances.

From a paper by Mr. A. Hewat in the *Assurance Magazine* (xxii. 286) it appears that the average amount of surplus annually divided among the assured by seventy-seven offices which have rendered valuation accounts to the Board of Trade since the passing of the "Life Assurance Companies Act, 1870," has been £2,285,000, or 23 per cent. of the annual premium income of the offices. The following average specimens of reversionary bonuses are taken from the returns of forty-one of those offices, whose average rate of annual premium is shown in the second column.

Age at Entry.	Average Premium.	Average Specimens of Reversionary Bonuses, per cent. per annum.				
		Years in Force.				
		5	10	15	20	25

50	4 9 9	1 7 8	1 9 3	1 11 10	1 15 1	2 0 5

Surrender values.

Surrender Values.—In those branches of insurance where the contract is one of indemnity against loss, the risk remaining the same from year to year—and where the consent of both parties, insurer and insured, is required at each periodical renewal—no question of allowance in respect of past payments can arise when one party or the other determines to drop the contract. It is quite recognized that the premiums are simply an equivalent for the risk undertaken during the period to which they apply, with a certain margin for expenses and for profit to the insurer, and that therefore a favorable issue of the particular contract supplies no argument for a return of any part of the sums paid. In life assurance, however, we have shown that the premiums contain a third element, namely, the portion that is set aside and accumulated to meet the risk of the assurance when the premium payable is no longer sufficient of itself for that purpose.

When a policy-holder withdraws from his contract with a life-assurance office, the provision made for the future in respect of his particular assurance is no longer required, and out of it a surrender value may be allowed him for giving up his right to the policy. If there were no reasons to the contrary, the office might hand over the whole of this provision, which, as we have seen, is in fact the reserve value of the policy. No more could be given without encroaching upon the provision necessary for the remaining policies. But the policy-holder in withdrawing is exercising a power which circumstances give to him only and not to the other party in the contract. The office is bound by the policy so long as the premiums are duly paid and the other conditions of assurance are not infringed. It has no opportunity of reviewing its position and withdrawing from the bargain should that appear likely to be a losing one. The policy-holder, on the other hand, is free to continue or to drop the assurance as he pleases, and it may fairly be presumed that he will take whichever course will best serve his own interest. If he is in failing health, he is the more likely to make an effort to keep the assurance on foot; if he has also fallen into adverse circumstances, his friends may aid him to maintain his policy for the benefit of those dependent on him, or he may dispose of it to some one who, knowing the circumstances, may be willing to give a high price for it, speculating on the chance of its becoming an early claim. All these things do happen, and the tendency obviously is that policies on deteriorated and unhealthy lives are kept in force, while those on lives having good prospects of longevity are more readily given up. Again, the retiring policy-holder, by withdrawing his annual contribution, not only diminishes the fund from which expenses are met, but lessens the area over which these are spread, and so increases the burden for those who remain. Considerations like these point to the conclusion that, in fairness to the remaining constituents of the office, the surrender value to be allowed for a policy which is to be given up should be less than the reserve value. The common practice is to allow a proportion only of the reserve value. Some offices have adopted the plan of allowing a specified proportion of the amount of premiums paid. This plan is not defended on any ground of principle, but is followed for its simplicity and as a concession to a popular demand for fixed surrender values.

Non-forfeiture system.

Another mode of securing to retiring policy-holders the benefit of the reserve values of their assurances is that known as the *non-forfeiture system.* This system was first introduced in America, whence it found its way to the United Kingdom, where it was gradually adopted by a large proportion of the assurance companies. In its original form it was known as the "ten years non-forfeiture plan." The policies were effected by premiums payable during ten years only, the rates being of course correspondingly high. If during those ten years the policy-holder wished to discontinue his payments, he was entitled to a free "paid-up policy" for as many tenth parts of the original sum assured as he had paid premiums. The system, once introduced, was gradually extended first to assurances effected by premiums payable during longer fixed periods, and ultimately, by some offices, to assurances bearing annual premiums during the whole of life. The methods of fixing the amount of paid-up policy in the last-mentioned class of cases vary in different offices, but the principle underlying them all is that of applying the reserve value to the purchase of a new assurance of reduced amount.

Disclosure of facts.

Conditions of Assurance.—An office, in entering on a contract of life assurance, does so in the faith that all circumstances material to be known in order to a proper estimate of the risk have been disclosed. These circumstances are beyond its own knowledge, and as the office for the most part (except as regards the result of the medical examination, which may reveal features of the case unknown to the proposer himself) is dependent on the information furnished by the party seeking to effect the assurance, it is proper that the latter be made responsible for the correctness of such information. Accordingly it is made a stipulation, preliminary to the issue of every policy, that all the required information bearing upon the risk shall have been truly and fairly stated, and that in case of any misrepresentation, or any concealment of material facts, the assurance shall be forfeited. In practice, however, this forfeiture is rarely insisted on unless there has been an evident intention to deceive. The other usual conditions of life assurance policies may be shortly noticed.

Days of grace.

1. *As to Payment of Premiums.*—A certain period of grace is allowed, most commonly thirty days, after each premium falls due. If payment is not made within that time, the presumption is that the policy-holder intends to drop the contract, and the risk of the office comes to an end. It may, however, be revived on certain conditions, usually the production of evidence of health and payment of a fine in addition to the premium. An impression used to prevail among the public that the offices were interested in encouraging the forfeiture of policies. If any such impression was ever shared by the offices themselves it must have long since passed away, as it will be found that every reasonable effort is now made on their part, not only to secure assurances but to retain them, and to afford all the facilities that can be extended to policy-holders with that object.

Foreign limits, etc.

2. *As to Foreign Travel and Residence, and as to Hazardous Occupations.*—When Mr. Babbage wrote his *Comparative View of Assurance Institutions* in 1826, voyaging abroad was scarcely permitted under a life policy. The Elbe and the Garonne, Texel and Havre, Texel and Brest, the Elbe and Brest, were the limits prescribed by most of the English offices. Even at a much later period the extra premiums charged for leave to travel or reside abroad were very heavy. But improved means of conveyance—in some places better sanitary appliances, and habits of living more suited to the climatic conditions—and, more than all perhaps, the knowledge that has been gained by experience as to the extent of the extra risks involved and the relative salubrity of foreign climates—have enabled the offices to modify their terms very considerably. The limits of free residence and travel have been greatly widened, and where extra premiums are still required, these are, as a rule, much lower than formerly. The assured are now commonly permitted to reside anywhere within such limits as north of 35° N. lat. (except in Asia) or south of 30° S. lat., and to travel to and from any places within those limits, without extra premium.

Military men (when on active service) and seafaring men are of course charged extra rates, as are also persons following specially dangerous or unhealthy occupations at home.

Suicide.

3. *As to Suicide.*—The policies of most companies contain a proviso that the assurance shall be void in case the person whose life is assured dies by his own hand. This proviso is analogous to that which renders void a fire policy if the insured becomes guilty of arson, or a policy of marine insurance if the vessel is wrecked intentionally by the owner. The event contemplated in the policy being brought about by the voluntary act of the assured, and not in the natural course of events, is a contingency not included in the scheme of insurance. In the case of life policies the general rule of law appears to be (see *The Law of Life Assurance*, by C. J. Bunyon) that the contract will be avoided unless the suicide takes place when the assured is insane and not accountable for his acts. Sometimes the proviso "whether insane or not" is inserted in policies. In the case of policies *bona fide* assigned, or otherwise held by a third party for an onerous cause, it is usual to exempt the assurance from forfeiture to the extent of the interest of such third party. The practice of assurance offices, however, in regard to suicides is more liberal than a strict application of legal principle, or of the conditions attached to life policies, would require. A few offices have abolished the suicide clause from their policies. A number of others, acting, we think, on a sounder principle, now limit its operation to a fixed period, the extent of which varies in different offices from six months to seven years from the date of issue of the policy. In cases happening within those periods, or when there is no express exemption from forfeiture, offices are usually ready to grant any relief which circumstances may seem to warrant, such as an allowance of the surrender value or a return of the premiums paid under the policy.

Indisputable policies.

The practice of rendering policies *indisputable* and free from restriction as to foreign travel or residence, after a certain period, has tended greatly to simplify the contract between the office and the assured, by setting at rest many points on which difficulty might arise. A declaration of indisputability covers any inaccuracies in the original documents on which a policy was granted, unless these inaccuracies amount to fraud, which the law will not condone under any circumstances.

Beginnings of life assurance.

History.—It does not appear that the principles of insurance were applied in any definite form to transactions depending on human life until about the 16th century. At that time, and for long afterwards in England, the private underwriters who carried on the business of insurance sometimes undertook risks upon lives for short periods, to cover contingencies of a temporary character. The premiums were very high, but this was in part necessary for two reasons—first, the insurers had no sufficient data upon which to estimate the risk they incurred; and secondly, the transactions were probably not numerous enough to secure anything like a regular average in the occurrence of claims. About the end of the 17th century several "annuity" schemes were formed, notably that of the Mercers Company of London, for the benefit of the widows and orphans of subscribers. These schemes, however, and numerous others of similar character promoted in the succeeding century, failed for lack of correct data and sufficient knowledge of the principles which should have guided their operations. But the idea of uniting the contributions of a number of persons in order to make a provision available on the death of each had taken some hold on the public mind. Its first practical embodiment in the direction of life assurance, but still far short of that system as it is now understood, was the foundation in 1706 by royal charter of "The Amicable Society for a perpetual Assurance Office." The scheme was simply to raise a fixed contribution from each member, and from the proceeds to distribute a certain sum each year among the representatives of those who died during the year. No one was to be admitted under the age of twelve nor above fifty-five (afterwards altered to forty-five), but all were to pay the same rate of contribution. In 1734 the society made arrangements for guaranteeing that the dividend for each deceased member should not be less than £100. This was the first approach to an "assurance" of a definite sum at death, *whenever that might occur.* The minimum dividend was afterwards increased, but still the society adhered to the plan of rating all members alike, irrespective of age. It was not until 1807 that the Amicable, under a fresh charter, began the practice of rating new members "according to the age and other circumstances." But that essential step in the development of assurance had been taken long before in another quarter. The theory of life contingencies had made considerable progress, chiefly through the labors of Halley, De Moivre, Simpson, De Parcieux, and Dodson, when in 1756 was projected "The Society for Equitable Assurances on Lives and Survivorships." Mr. Dodson, wishing to have his life assured,

The Amicable Society.

The Equitable Society.

found himself excluded from the Amicable on account of his being more than forty-five years old. This led him to the determination "to form a new society upon a plan of assurance on more equitable terms than those of the Amicable, which takes the same premium for all ages," and he secured the support of various persons who were willing to join him if the intended society could be established by charter. He did not live to see his purpose accomplished. The petition for a charter of incorporation was presented in 1757, and after a delay of four years it was finally refused, whereupon a remnant of the original subscribers set about constituting the society under a deed of settlement, and business was commenced in 1762. The Equitable possessed from the outset all the essential features of a life assurance office. It was to issue policies for the assurance of fixed sums on single or joint lives, or on survivorships, and for any term. Premiums were to be regulated according to age. Lives were to be admitted with due regard to their state of health and other circumstances. Provision was made for the investment and accumulation of the funds, and also (although imperfectly) for the disposal of any surplus that might arise. As may be supposed, the original scheme was defective in many points of detail, but under the teachings of experience there was soon initiated that course of improvement in the system of assurance which has continued to the present day.

Other early offices.

More than forty years before the foundation of the Equitable, charters of incorporation had been granted to two companies which have ever since held an honorable position among assurance institutions, the Royal Exchange and the London Assurance. These included life assurance in their schemes, but appear to have at first transacted it only to a limited extent and in the form of temporary risks such as were taken by the private underwriters.

Before the close of last century the labors of Price and Morgan had developed in an important degree the theory of life contingencies; the Northampton Table had supplied what was then esteemed a sound basis for such calculations; and the career of the Equitable Society had demonstrated the practicability of conducting life assurance business on a large scale. Within the period mentioned other four life offices were established, one of which, the Pelican, founded in 1797, is now in existence. The present century thus commenced with eight offices transacting, in a more or less complete form, the business of life assurance in Great Britain and Ireland. But the success which attended those older societies, particularly the Equitable, soon led to the formation of other offices, and as these increased in number and activity, public attention became more and more attracted to assurance, both as a means of employing capital and as an advantageous form of co-operation for mutual benefit.

Joint-Stock Companies Act, 1844.

Up to the year 1844 over one hundred and forty companies and societies had been established on a more or less solid footing for the purpose of transacting life business, either alone or in connection with other forms of insurance, and of these offices upwards of one hundred remained in existence. But abuses had taken place in connection with all kinds of joint-stock enterprises, and this led to a parliamentary inquiry which resulted in the Joint-Stock Companies Act of 1844. This Act provided specially for the regulation of insurance companies, and among other things imposed upon them the duty of giving in annual statements of their affairs to be placed upon public record. Not many years passed, however, before the attention of parliament was again called to life assurance in consequence of the exposure of certain unwise and fraudulent schemes. A select committee was appointed to make inquiries, and they reported to the House in 1853, having examined several public officials and many leading actuaries of the day. They found that the law as it then stood was very defective, that it did not afford the security which was contemplated by the Act of 1844, and that the provisions of that Act had been very imperfectly carried out. In particular the financial returns had not been satisfactorily made. No special form of accounts had been prescribed by the Act, nor was there even any authority provided by it to compel the returns to be made. As a matter of fact, the Act had been followed by the promotion of a large number of bubble insurance schemes of various kinds.

Select committee, 1853.

The committee had very fully before them the whole question as to the policy of Government interference in matters relating to life assurance. Their conclusion was that assurance differed so much from ordinary business as to call for separate and special legislation; and in that view they made certain recommendations—(1) as to precautions to be taken in regard to the formation of new associations, and (2) as to requiring the publication of valuation returns and accounts giving information on specified particulars. Assurance companies were excepted from the next Government bill relating to joint-stock companies, but nothing was done in the shape of legislation, such as that proposed by the committee, until the passing of the Life Assurance Companies Act, 1870, in the framing of which the assurance companies took a considerable share.

Life Assurance Companies Act, 1870.

This Act requires a deposit of £20,000 to be made in the Court of Chancery by every new company proposing to transact life assurance business; requires (in the case of companies transacting other kinds of business) the receipts under assurance and annuity contracts to be kept separate from other receipts, in order to form a security for the policy-holders and annuitants; prescribes forms for annual accounts and for periodical valuation reports and statements, to be rendered to the Board of Trade and to be annually laid before parliament; forbids the transfer or amalgamation of companies without judicial authority, which is not to be given until the policy-holders concerned have been fully informed as to the nature and terms of the arrangement, nor if policy-holders representing one-tenth or more of the total sums assured dissent; and provides for the winding-up of any company (1) in case of default in complying with the requirements of the Act, or (2) on its being proved to the satisfaction of the court, in view of the contingent or prospective liabilities, that the company is insolvent. In the latter case the court may, if it thinks fit, reduce the amount of the contracts of the company in place of making a winding-up order.

It will be seen that the principle upon which the Act proceeds, in so far as it regulates the management of existing offices, is to require full particulars to be furnished as to their financial condition, and to leave all concerned to form their own judgment upon these. The Government attempts no supervision of the companies further than to see that they comply with the requirements of the Act. But the very publicity now given to their affairs exercises a most wholesome influence, wherever that is needed, on institutions which are peculiarly dependent for their success on the estimation in which they are held by the public. It cannot be pretended that the material furnished by the returns under the Act for forming an estimate of the condition of offices is such as to be wholly intelligible to the mass of those interested in it. Nor was this to be expected. The principles of life assurance, which we have endeavored in some measure to explain in the present article, are such as to require considerable study, and even special training, for their full appreciation. But the material required by the Act is there, to be interpreted by those who have made themselves familiar with its import and bearing, and the public have themselves to blame in great measure if they remain in ignorance as to the real condition of any offices in which they may be interested. The provisions of the Act in regard to amalgamations and to the formation of new companies have also had their effect. It is now no longer practicable to commence a life assurance company without a substantial guarantee for the good faith of those engaged in it; and the possibility of ruinous amalgamations, such as those which aided so materially in bringing about the collapse of the famous Albert and European offices, may be regarded as a thing of the past. Unfortunately the provisions of the Act in regard to winding-up have more than once been brought into requisition, but it is safe to say that since it came into effect no one who had sought competent advice need have been involved in loss by joining any of the offices which have thus passed under its operation.

On the whole, the Life Assurance Companies Act of 1870, although not without its defects, may be regarded as in many respects a satisfactory measure. In some unimportant particulars it has been amended by two subsequent Acts in 1871 and 1872.

Married Women's Property Act, 1870.

The year 1870 witnessed the passing of another Act which has an important bearing on life assurance. Under clause 10 of the Married Women's Property Act, 1870, assurances may be effected by married women on their own lives or the lives of their husbands, for their separate use, and by married men on their own lives for the benefit of wife, or wife and children, free from the claims of creditors. In 1880 the Scottish life offices prepared a short bill containing similar provisions in regard to assurances, but with certain improvements on the English Act, and it was passed into law as the Married Women's Policies of Assurance (Scotland) Act, 1880.

Scotch Act.

Statistics of 1880.

The Blue-Books containing the returns made under the Life Assurance Companies Act afford a vast amount of information as to the financial condition of British life offices. From an abstract in Mr. White's *Insurance Register* for 1881 we gather the following particulars in regard to one hundred and seven companies which furnished returns during the year 1880. The premiums received in one year by those companies amounted to £13,174,848 and the interest and dividends on investments to £5,342,988. The sums paid in claims during the same period were £11,149,730; for surrenders of policies £720,406; and as cash bonus or in reduction of premiums £763,704. The total amount of funds held by the companies (including, however, £6,151,479 of fire insurance funds) was £143,813,793. Of this sum £120,131,541 represented the life assurance and annuity funds. The amount of paid-up share capital embarked in these enterprises was £10,961,744, in addition to which (but also included in the above sum of £143,813,793) there were reserve and other funds amounting to £6,569,029. These statistics include the business of "industrial assurance," transacted by a few offices—a system by which small sums are secured on the lives of persons in the humbler ranks of life by the payment of weekly or monthly contributions. The premium income from this source was upwards of £1,600,000; the claims reached fully £600,000; and the funds in hand in connection with this description of business amounted to upwards of £1,100,000.

The Act does not require an annual statement of the existing business of assurance companies, nor does it render compulsory the publication of the amount of new assurances annually effected with them; and, as the companies do not all give those details in their published reports, it is impossible to state with accuracy the amount of assurance business transacted by the British offices. Of the 107 companies whose accounts are summarized above, 63 reported in the year 1880 new assurances amounting to £22,551,626, including, however, in many cases, sums reassured with other offices. It is roughly estimated that the total assurances in force with all the companies amounted in 1880 to £420,000,000.

Government life insurance.

Besides the business transacted by British assurance companies there is a scheme of Government life insurance authorized by the Act 27 & 28 Vict. cap. 43, and worked in connection with the Post Office. By a recent parliamentary return it appears that, from the commencement of the scheme in 1864 to 31st December, 1878, there had been issued 5844 policies insuring in all £460,000, and there had been paid on the death of nominees about £25,000.

American assurance.

In the United States of America life assurance has attained a greater relative importance among financial institutions than in any other country. Its history there extends back to an early period, but the system has received its main development in comparatively recent times. During the years which immediately followed the close of the civil war it grew with unparalleled rapidity. The social disorders of the period excited anxiety for the future. and directed earnest attention to institutions which promised exceptional security. The general Government, by its financial administration, and especially by its issues of paper money, furnished a powerful stimulus to the speculative tendency in this as in every branch of business. New companies were established in great numbers: new plans and features of assurance contracts were devised; thousands of energetic agents canvassed the community with their solicitations; and the published reports of the assurance companies reflected, in a high degree, the fictitious prosperity of the period of inflation. The financial crisis of 1873 applied to the companies a test of great severity. The mushroom institutions of recent growth fell rapidly; and, while the standard societies, which were administered with wise conservatism, and which had always held the greater part of the business, were unshaken, their growth was seriously checked.

The following figures (for which we are indebted to the *Insurance Year Book*, Chicago, 1880) give in outline the history of this period. They represent the aggregate business of the companies reporting to the New York insurance department. The figures for 1879 include "industrial assurance," a branch of business but recently developed in America.

No. of Companies.	Year ending Dec. 31.	Policies issued during Year.		Policies in force at end of Year.	
		Number.	Amount of Assurance.	Number.	Amount of Assurance.
27	1864	59,198	$155,803,897	146,729	$395,703,058
43	1867	158,605	471,611,744	401,140	1,161,729,776
71	1870	237,180	587,863,236	747,807	2,023,884,955
56	1873	199,050	465,614,001	817,081	2,086,027,178
38	1876	99,036	232,665,489	706,179	1,735,995,190
34	1879	112,025	168,633,035	653,905	1,457,255,513

From 1873 to 1879 the number of companies and the aggregate amount at risk steadily decreased. Since then, although no new companies have been organized, there have been no failures, and a healthy and natural increase has been observed in the business of the existing offices. The following table shows the aggregates of the principal items in the business of the forty-two most important companies in the United States for the years 1879 and 1880, as compiled by the *New York Spectator*:—

	1879.	1880.
Total assets, December 31	$414,271,442	$442,055,862
" liabilities " (including reserve)	353,684,927	361,452,788
Premiums received during the year	50,753,970	54,939,987
Total income " "	79,437,280	79,216,202
Death claims paid "	20,665,045	22,227,107
Endowment claims "	9,646,598	8,462,768
Paid for purchased and surrendered assurance	13,815,491	10,247,024
Paid for dividends to policy-holders	13,470,639	13,263,592
Total disbursements during the year	71,433,351	62,038,066
Assurances written " "	177,891,719	194,166,890
Total assurances in force, December 31	1,515,378,042	1,554,093,611

Legislation.

A subject of special interest in connection with life assurance in America is the legislation by which it is regulated. While the national Government, under the constitution of the United States, has supreme control over all commerce between the States, the courts hold that insurance in its various forms is not commerce, and that corporations created by a State have no corporate powers beyond the limits of that State, and can transact no business beyond those limits, except on sufferance of the local Government. Hence the life assurance companies are the creatures of State law, and are controlled by the legislatures of the States in which they operate. The first systematic attempt to regulate the business by Government supervision was made by the State of Massachusetts under a statute passed in 1858 establishing an "insurance department." New York adopted a similar law in 1859, and the example has since been followed in nearly all the States, even in those which have no important assurance companies of their own. Each State has its own peculiar laws, and these undergo frequent changes in detail as successive legislatures attempt to improve or to reform the business, but the general character of the supervision exercised is the same in the different States, and is as follows. A company may be organized at any time for the business of assuring lives and granting annuities, by obtaining from the proper officers of the State the approval of its name and fundamental law or charter, and by depositing with the insurance department a stated sum, usually $100,000, in prescribed securities, as a guaranty of good faith. Since no charters are now granted except under this general law, it is no longer possible to establish a company except by the deposit of a considerable sum in advance,—so that purely mutual companies cannot now be founded; but it is customary to limit the amount of profit upon the capital to a reasonable rate of interest, and all surplus beyond goes to the policy-holders. In some instances the capital stock of these "mixed companies" has been redeemed, after their successful establishment, leaving them purely mutual.

Registered policies.

In New York and some other States the insurance department may receive further deposits, representing the reserve or present value of policies, and hold them accumulating in trust, for the security of those particular policies, which are "registered" in the State treasury. This scheme was pressed with vigor a few years ago, as offering peculiar protection, but several companies which adopted it have failed, and the settlement of the claims of creditors upon the funds held by the State has been the cause of much delay and costly litigation.

Superintendent of insurance.

In each State there is a superintendent or commissioner of insurance whose powers and duties towards the companies are varied and important. The companies must return to him under oath every year full statistics of their business in all departments, showing the precise investments of their funds, the amount and sources of their income, the expenditure for every purpose, and a schedule of policies with the elements for valuing them. It is the superintendent's duty to see that the investments are made in accordance with the laws, which limit the companies to securities popularly regarded as the safest; to make every inquiry which he deems it "desirable for the public interest" to have answered; to make a valuation of the policies of each company by the legal standard;[1] and to report to the legislature every year in full the results of his inquiries and calculations. It is his duty, "whenever he shall deem it expedient so to do," and in particular whenever he shall suspect any statement made by the officers, to "investigate" the affairs of each life assurance company,—that is, to overhaul its books and accounts, examine its muniments of title, and test and scrutinize every part of its administration. No company chartered by any other State or government can do any business within the State, except under his license and certificate that it has complied with all the laws; and exclusion from the State is the penalty for neglect to answer any question concerning its business which he may ask. In several States he is required to exclude any company which shall take an appeal from the courts of the State to a court of the United States, in a case arising between it and a citizen.

The most important duty imposed on the superintendent is the administration of the legal test of solvency. In New York and most of the other States, his valuation, according to the legal standard, must be made by the net-premium method, and if any company is unable to meet this test by actual possession of the requisite amount of funds, he must commence legal proceedings for its dissolution, and the distribution of its assets as in bankruptcy. The Act making this course imperative in New York was passed in 1879, but many years earlier the practice had become fixed of requiring a company to meet a net valuation of its obligations, or be deemed insolvent. The fairness of this unbending application of the net-premium mode of valuation as a test of mere solvency, and the efficiency of the check supplied by a too exclusive reliance on such a test, have often been called in question.

Winding up.

When an insolvent assurance company is wound up, the rule commonly followed by the courts of equity in distributing the proceeds is to recognize each policy-holder as a creditor for the amount of reserve corresponding to his assurance at the time of the declared insolvency. The representatives of a policy-holder who dies before the actual distribution may claim for the amount of the policy, discounted back to the date of insolvency. The whole process of winding up would be much less unsatisfactory than it has proved, if the courts and the departments could make a prompt and inexpensive distribution. But in practice there is too much danger of the distribution being delayed until the available assets have been largely dissipated in receivership and legal expenses.

Non-forfeiture laws.

In New York, and several other States, the legislature has interfered to prevent the forfeiture of assurances by the failure to pay a premium, and has undertaken to regulate the payment of surrender values and the grant of paid-up policies in such cases. There is not, however, any general agreement among the different States as to the basis on which such allowances are to be computed. It is too soon to judge finally of the effect of these non-forfeiture laws upon the business; but the impression is believed to be growing among thoughtful policy-holders that they are too favorable to withdrawing members, and tend to weaken the companies, by encouraging the retirement of the most healthy and profitable lives. Laws of this kind usually proceed upon the theory (which we venture to think an erroneous one) that the reserve for each particular assurance is to be looked upon as in some sense the property of the individual policy-holder.

American mortality tables.

The American Experience Table adopted by New York State as the official standard of valuation was constructed by Mr. Sheppard Homans from the statistics of the Mutual Life Insurance Company of New York City. Other valuable tables of American experience have been published, such as that given by Mr. W. S. Nichols (*Ass. Mag.*, xix. 28) from the experience of the Mutual Benefit Insurance Company of New Jersey, and a later collection of the experience of the Mutual Life, more extensive than the first, to which Professor Bartlett has devoted great attention. Some years ago the Chamber of Life Insurance in America (an association formed among the American assurance offices) undertook the collection and arrangement of the experience of a number of the companies in the States. Their labors when completed will no doubt throw much additional light on the value of assured life in America. Meantime Professor Bartlett brings out in his tables a longer duration of life than that indicated by experience in England, and Mr. Nichols points out a higher relative mortality among young lives in America. If the latter peculiarity be well established, it will follow that the reserves required by American offices may be smaller than those required by English offices, even if the same rate of interest be employed in the calculations.

---

[1] Each State has its own official standard of valuation. In New York, for example, the American Experience Table of Mortality, combined with 4½ per cent. interest, is the standard. In Massachusetts it is the Seventeen Offices' Experience (British) Table, and 4 per cent.

Bonus system.

An interesting feature in the practice of many American offices is their dividing profits on the "contribution method," so called because it aims at returning to each class of policy-holders a share of the surplus proportionate to the amount contributed to its formation. An explanation of this method by Mr. Homans, by whom it was originated, will be found in the *Assurance Magazine*, vol. xi. p. 121. Bonuses, or "dividends," as they are called in America, are largely taken in cash, but they may be applied in augmentation of the sums assured.

Tontine system.

The "Tontine" system of assurance has come into prominence of late years. The policy-holders under this plan agree that no dividend, return-premium or surrender value shall be received for a term of years called the "tontine period;" but that the entire surplus from all sources, including lapses, shall be accumulated to the end of that period, and then divided among all who have maintained their assurances in force. The tontine companies usually offer this plan as an alternative with the ordinary mode of assurance, and large numbers of applicants select it.

Canada.

In Canada the course of legislation with regard to assurance has brought about a state of the law very much resembling that in the United States. After the passing of the latest Act in 1877,—which, among other things, requires all companies to keep separate assets in Canada against their liabilities there,—several British and American offices withdrew from transacting new business in the Dominion. From the report of the superintendent of insurance for the year 1879 it appears that the number of companies licensed for the transaction of life assurance business in Canada for that year was thirty-six. Of these thirteen did not transact new business. The following are the Canadian statistics for the year referred to.

	Assurances effected during the Year.		Assurances in force at end of Year.	
	Companies.	Amount Assured.	Companies.	Amount Assured.
		$		$
Canadian Companies.	7	6,112,706	7	33,246,543
British Companies.....	11	1,877,918	18	19,410,829
American Companies	5	3,363,600	11	33,616,330
Total..................	23	11,354,224	36	86,273,702

Australasia.

In Australia and New Zealand there were in 1879 (including the New Zealand Government Insurance Department) ten institutions for life assurance business. The total amount of new assurances granted by them was between £3,000,000 and £4,000,000, upwards of £2,000,000 of which was transacted by one office, the Australian Mutual. The ten offices had in force at the close of the year nearly 70,000 policies, assuring upwards of £23,000,000.

India, etc.

In India, at the Cape of Good Hope, and in the West Indies there are native assurance offices, but the business in those places is largely transacted by companies whose headquarters are in Great Britain.

On the continent of Europe the practice of life assurance has not as yet become so widespread as in English-speaking countries. There are assurance companies in various Continental countries, but it is chiefly in France and Germany that any extensive development of the system has taken place.

France.

In France life assurance was later in taking root than in Great Britain, and its development has been much slower. There are, however, several large and solid life offices in that country dating back for a considerable period, besides a number of more recent growth, and the business is now making remarkable progress. The oldest French company, La Campagnie d'Assurances Générales, founded in 1819, issued in the year 1880 policies to the amount of 81,000,000 francs,—a year's business unequalled in magnitude in the experience of any British office. The following figures, taken from the *Moniteur des Assurances*, shows the rapid increase of business among the French life offices in recent years. They represent the total amount of new assurances effected in each year:—

	Francs.		Francs.
1875	254,000,000	1878	315,000,000
1876	284,000,000	1879	337,000,000
1877	278,000,000	1880	435,000,000

There are now twenty companies in France, the aggregate of whose existing assurances must considerably exceed 2,000,000,000 francs.

Germany.

In Germany (including German Austria and German Switzerland) there are fifty companies transacting life assurance business, whose aggregate new assurances in the year 1879 amounted to 275,787,828 marks. At the end of that year the number of lives assured was 797,343, for sums amounting to 2,534,764,076 marks. There is now in progress an extensive investigation as to the mortality of assured lives in Germany, to which upwards of twenty German offices have contributed their experience. (G. M. L.)

III. Marine Insurance.

Definition.

Marine insurance is a contract by which one party, the "insurer" or "underwriter," engages for a stipulated premium to protect another party, the "assured," against loss arising from certain perils, or sea risks, to which his ship, goods, or other interest may be exposed during a specified voyage or period of time.

The policy.

The policy of insurance, or instrument which contains the contract, is a printed form, with spaces left blank for the insertion in writing of the particulars of the agreement. The form in general use appears to have been introduced with the earliest practice of British marine insurance. Although worded in a confused and ambiguous manner, its meaning has been clearly defined by a series of legal decisions on the debatable points; and in all cases the written conditions overrule any of the printed clauses that might seem inconsistent with them.

Stamp Act.

The stamping of policies is at present regulated chiefly by the Customs and Inland Revenue Act, 1867, 30 Vict. c. 23. This Act provides that no contract or agreement for sea insurance shall be valid unless expressed in a policy; that all policies must be stamped before signature; that no policy shall be pleaded or admitted as evidence in any court, unless duly stamped; and that no policy can be made for any time exceeding twelve months. The stamp duties are—

On Voyage Policies.—For every £100 insured and for any fractional part of £100, 3d.

On Time Policies.—For every £100 insured, and for any fractional part of £100, where the time does not exceed six months, 3d.; where the time exceeds six months, and does not exceed twelve months, 6d.

If the separate interests of two or more persons be insured in one policy the stamp must cover each fractional part of £100, in the amounts of such separate interests, as if it were a full sum of £100. Where insurance is made for a voyage, and also for time, or to cover any time beyond twenty-four hours after the ship's arrival at her destination, the policy is chargeable with duty as a voyage policy, and also with duty as a time policy. The penalty exigible from any person engaged in effecting or subscribing policies which have not been duly stamped is £100.

By the Act 33 & 34 Vict. c. 97, § 117, it is provided that policies made abroad, but in any manner enforceable within the United Kingdom, are liable to the duty, and may be stamped at any time within two months after they have first been received in the United Kingdom. Further, by the Act 39 Vict. c. 6, § 2, it is now provided that, for the purpose of being given in evidence, any policy may be stamped after execution, on payment of the penalty of £100.

The slip. In practice it is usually desirable to conclude an agreement for insurance at once, lest some subsequent intelligence should induce either party to recede; and it is customary for the underwriter to sign a "slip," or short memorandum of the insurance, until the stamped policy can be completed. But such memorandums, however obligatory in good faith, are not legally binding. The assured, however, is under no obligation to communicate to the underwriter a material fact coming to his knowledge between the date of the slip and that of the policy. And, when a valid policy exists, the slip is admissible in evidence to throw light on the circumstances under which the risk was offered and accepted.

Policy without interest. In order to give validity to the contract, it is necessary that the assured have a right of property, or "interest," in the thing assured. A policy without interest is held to be a wager; and it is declared by the 19th Geo. II. c. 37 that policies bearing the words "interest or no interest," or "without further proof of interest than the policy," or "without benefit of salvage to the insurer," or any policies made by way of gambling or wagering, shall be null and void. The expected profits of a sea adventure may be included in the value of the property for insurance; but an unwarrantable or fraudulent over-valuation might render the policy void even in respect of the value actually proved.

Assignment of policies. By the Act 31 & 32 Vict. c. 86 it is provided that, "whenever a policy of insurance on any ship, or on any goods in a ship, or on any freight, has been assigned so as to pass the beneficial interest in such policy to any person entitled to the property thereby insured, the assignee of such policy shall be entitled to sue thereon in his own name, and the defendant in any action shall be entitled to make any defence which he would have been entitled to make if the said action had been brought in the name of the person by whom, or on whose account, the policy had been effected."

Valued policies. A valued policy is one which contains a specific valuation of the interest insured. This valuation forms an essential element in the adjustment of all claims under the policy, and cannot be set aside except on the ground of fraud. The burden of proof, in any averment of fraudulent over-valuation, lies on the underwriter.

Open policies. An open policy is one in which the value of the interest insured is not specified. In claims under such policies the assured must prove the value of the thing insured. The value of a ship for insurance is what she is actually worth at the commencement of the voyage, including all her stores, provisions, and outfit, money advanced for seamen's wages, and costs of insurance. The difficulty of *proving* a precise value in the case of ships is sufficiently obvious; and, to avoid disputes, policies on them ought always to be valued, as is the usual practice. The value to be proved under an open policy on goods is their first cost, including the expenses of shipment, with any portion of the freight that may have been prepaid, and the costs of insurance. The value to be proved in open policies on freight is the amount of the manifest or freight list, excluding such freight as may have been paid in advance.

Over-insurance. When the value proved under an open policy falls short of the sum originally insured, the difference, which is technically termed an over-insurance, is treated as a deduction to be made from the amount of the policy. On this footing a proportionate part of the premium is returnable to the assured, who, on his part, can make no claim on the underwriter for loss or damage beyond the value of his interest as actually proved. If, on the other hand, the value proved exceed the amount of the policy, the assured is regarded as "his own underwriter" to the extent of such excess; and the amount of loss or damage, if such has arisen, is apportioned on this footing between the parties relatively to their several proportions of the total value.

Short interest. A "short interest" arises when only a part of the interest insured has been exposed to risk, as when some portion of the goods specified in the policy have not been loaded on board of the ship. This case is treated in the same manner as that of over-insurance, from which indeed it does not essentially differ.

Double insurance. Double insurance takes place when the same interest has been insured twice or oftener. This frequently occurs, either through mere inadvertence, or from the want of definite information on the part of the respective persons concerned in the transaction. In such cases, the usual practice is that all the underwriters make a return of premium, in proportion to the amounts of their respective subscriptions, for the excess of the sum insured above the actual value of the interest,—the liabilities of the several underwriters under the different policies being of course proportionally diminished. To this rule, however, there are two important exceptions. One of these occurs when two or more persons insure the same thing, in order to protect the distinct interests which they may individually have in it; the other, when the circumstances are such that a claim for loss might have been brought against one set of underwriters before the other set had become liable at all.

Reinsurance. Reinsurance was formerly illegal in England except in the event of the death, insolvency, or bankruptcy of the original insurer. This law subsisted for about one hundred and sixty years, but it was repealed by the 27 & 28 Vict. c. 65, and the subject of reinsurance was further regulated by the 30 & 31 Vict. c. 23. Reinsurance is now recognized by these statutes as a perfectly legal contract.

Duration of risk. The risk on the ship, in voyage policies, commences "at and from" the place specified in the policy, and continues till she arrives at the destination specified, and has been there moored twenty-four hours in good safety. On goods the risk begins with their loading and ends with their discharge at the specified ports. On freight the risk usually commences with the shipment, and terminates with the landing of the goods; but if there be a contract of affreightment, under which the goods have been provided for shipment, the risk is held to commence as soon as the ship is in readiness to take them on board. After the risk has once commenced, the whole premium is earned, even although the voyage should not be prosecuted, and the actual risk of the insurers be thereby confined to the mere lying of the ship at the port where the insurance was to commence. But if the risk should not commence at all, or, in technical phrase, if the "policy should not attach," the premium must be returned to the assured.

Deviation If the ship should deviate from the regular and usual course of the specific voyage insured without necessity or reasonable cause, the underwriter is thenceforth discharged from all liability under the policy. The insurance becomes void as soon as such deviation begins; and consequently it is quite immaterial whether a subsequent loss of the ship should happen during the actual deviation or after the ship had returned to her course, the insurer being no longer concerned. It is also immaterial whether the assured was or was not cognizant of the deviation. A mere intention to deviate will not vitiate the policy; but if the ship have sailed on a different voyage from that specified, the insurer is discharged, although the loss should happen before reaching the point of divergence in the two voyages. An unjustifiable delay in the prosecution of the voyage operates as a deviation. The causes which justify deviation are such as to refit the ship after she has been disabled, to avoid an enemy or an impending storm, or to save the lives of seamen in distress.

Seaworthiness.

In all voyage policies it is an implied condition of the contract that the ship shall be seaworthy at the commencement of the risk. By this is meant that the ship shall be in a fit state, as to repairs, equipments, crew, and all other respects, for encountering the ordinary perils of the voyage insured, at the time of sailing on it. Seaworthiness is a condition precedent to the contract; and, therefore, where the ship is originally unseaworthy, the underwriter is discharged even although the loss should result from causes independent of the particular deficiencies constituting the unseaworthiness. It is not material whether the assured is or is not cognizant of the defects rendering the ship unseaworthy; and this rule applies indiscriminately to the owners of the ship and the proprietors of the goods on board. There is no engagement that the vessel shall continue to be seaworthy after the voyage has been commenced; but it is the owner's duty to take all reasonable means to keep her so. The burden of proof in any averment of unseaworthiness lies on the underwriter, unless where the ship, without adequate cause, becomes leaky soon after sailing. It is now settled law that in time policies there is no implied warranty of seaworthiness at any period of the risk. This was decided in the cases of Gibson *v.* Small (June, 1853), and Fawcus *v.* Sarsfield (March, 1856), and more recently by the House of Lords in Dudgeon *v.* Pembroke (March, 1877).

Misrepresentation.

The contract of insurance being pre-eminently one based on the assumption of perfect good faith between the parties, it is the duty of the party wishing to effect the policy to make a true disclosure of every circumstance likely to affect the underwriter's estimate of the risk. The concealment or misrepresentation of material facts, or the representation of anything not consistent with the facts, will render the policy void. This rule holds good even where the concealment or misrepresentation may have resulted from a mistake, without the intention to deceive. If the underwriter has actually been deceived, whether wilfully or by mistake, the risk is different from that understood and intended to be run; and on this ground he is discharged. The materiality of a concealment or misrepresentation depends, not on its eventual influence on the result of the risk, but on its immediate influence on the judgment of the underwriter at the time of effecting the insurance. The loss may arise from causes totally unconnected with the facts concealed or misrepresented, but the policy may nevertheless be void, because a true disclosure of the facts at the time of effecting it might have led the underwriter to decline the insurance altogether, or to accept it only at a higher premium. If an agent be employed to effect the insurance, he is bound to communicate to the underwriter, not only all the material facts disclosed to himself by his principal, but also any other material facts which may have come to his knowledge from other sources. If either the principal or the agent fail to communicate such facts, the policy will be void. Should any material fact come to the knowledge of the parties wishing to effect the insurance after they have sent away an order to have it effected, they are bound to intimate such fact without delay, so that the underwriter may be informed of it (if there should still be time) before he has accepted the risk. The suppression of information tending to show that the ship was overdue, or that there were rumors current as to her having met with some accident (even though it afterwards appeared that these rumors were unfounded), is concealment fatal to the validity of the contract. It has also been held that a policy was void because the agents employed to effect it failed to inform the underwriters that their principal had instructed them to wait the arrival of the ship for a certain number of days before acting on the order to insure. Misrepresentations of the terms on which other underwriters have agreed to accept the insurance will be fatal to the validity of the contract, as well as misrepresentation of the risk itself. It may be observed generally that every circumstance represented to the underwriter ought to be at least substantially true. A mere expression of opinion or expectation does not of course amount to a positive representation of facts, but the opinion or expectation expressed must itself be genuine, since, if it appeared that it had been only a pretence, or inconsistent with anything within the actual knowledge of the assured at the time, the policy might be vitiated. When an express "warranty" is given, its terms must be literally complied with, otherwise the policy will be void. The chief distinction between a warranty and a representation is that the former is always inserted in the policy, while the latter is never so inserted; and the effect of this is that, while a representation affects the contract only in so far as it may be found to have been material to the risk, a warranty precludes all questions as to materiality, its express terms superseding any such inquiry.

Perils insured against.

The perils insured against are described in the printed form as the "adventures and perils of the seas, men-of-war, fire, enemies, pirates, rovers, thieves, jettisons, letters of mart and counter-mart, surprisals, takings at sea, arrests, restraints, and detainments of all kings, princes, and people, of what nation, condition, or quality soever, barratry of the master and mariners, and all other perils, losses, and misfortunes that have or shall come to the hurt, detriment, or damage of the said goods, merchandises, and ship, etc., or any part thereof." It may be observed that, as a general rule, the underwriters are liable only for such losses as are proximately caused by the perils insured against. For the remote consequences of these perils, such, for instance, as the loss of markets through delay, they are not responsible. But, on the other hand, if a loss has been proximately caused by a peril insured against, the underwriters are not relieved from liability, although such loss may have been remotely occasioned by the acts or negligence of the assured or his agents. The reason for this rule, as given by Lord Bacon, is that "it were infinite for the law to consider the causes of causes, and their impulsions one on another; therefore it contenteth itself with the immediate cause."

Losses resulting from breaches of the revenue laws or of the law of nations, or from illegal voyages generally, are not covered by the policy. The risk of "thieves" applies only to plunder committed by open violence, and does not cover losses by secret theft. The illegal acts of the master and crew, if committed without the privity of the owners, will amount to barratry, so as to render the underwriters responsible for them; but if the master be also owner of the ship, none of his acts will be held as barratrous. A shipmaster, however, who is only part owner may commit barratry as against his co-owners and their underwriters. If the assured be the subject of a foreign state, British underwriters will not be liable for the acts of that state, unless it appear from the form of the policy or from the circumstances of the case that the intention was to insure against such risk. Losses by the ordinary wear and tear of the ship, or by the natural deterioration or decay of perishable goods, are not chargeable to the underwriters.

Duty of assured in case of damage.

The printed form of the policy declares that "in case of any loss or misfortune it shall be lawful to the assured, their factors, servants, and assigns, to sue, labor, and travel for, in, or about the defence, safeguard, and recovery of the said goods and merchandises, or ship, or any part thereof, without prejudice to this insurance: to the charges whereof we, the assurers, will contribute, each one according to the rate and quantity of his sum herein insured." The object of this clause is to permit the assured to take measures for the recovery of the property without losing any right of abandonment he might have in the circumstances. Although the language of the clause is only permissive, it is a settled rule that the assured is bound so to labor for the recovery of the property. The best practical rule for the assured to follow in cases of partial loss or damage is to act in the circumstances as a prudent man would do if uninsured.

The memorandum.

An important clause in the printed policy is what is called the "memorandum," which is as follows:—"Corn, fish, salt, fruit, flower, and seed are warranted free from average, unless general, or the ship be stranded. Sugar, tobacco, hemp, flax, hides, and skins are warranted free from average under 5 per cent. And all other goods, also the ship and freight, are warranted free of average under 3 per cent., unless general, or the ship be stranded." The effect of this clause, as interpreted by legal decisions, is to free the underwriter from claims for particular average (or partial damage), or from such claims if under the rates specified, unless the ship be stranded. But if the ship be stranded, he is liable for such claims, whether caused by the stranding or not. For losses of the nature of general average the underwriter is liable whether the ship be stranded or not, and whether the amount be over or under the rates mentioned in the memorandum.

It is frequently a matter of some difficulty to determine whether a ship has been stranded within the meaning of the memorandum. A mere touching or striking, whether on a rock, bank, reef, or other object, will not constitute a stranding, unless the ship settles down and remains fixed for some definite time. The amount of damage sustained is not material to the question either way. Where a vessel takes the ground in the ordinary and usual course of the navigation in a tidal river or harbor, on the ebbing of the tide, or from natural deficiency of water, this is no stranding. It is essential to a stranding that the ship should take the ground by reason of some unusual or accidental occurrence. A voluntary stranding to save the ship from sinking is within the meaning of the memorandum, although the ship should be run into a tidal harbor for the purpose.

Total loss and abandonment.

When an absolute total loss occurs, the assured is entitled to recover the amount of the policy, without giving notice of abandonment. When the subject insured, without being wholly destroyed, is so seriously injured, through the perils insured against, that its recovery might involve greater expenses than its eventual value would cover, it forms a "constructive total loss," and the assured is entitled to give notice of abandonment to the insurers, and to claim the amount of the policy. (See ABANDONMENT.) It is only, however, when the circumstances seem to involve a virtual loss, as distinguished from a deterioration of the property, that notice of abandonment can be competently given; and, unless the abandonment be accepted, the ultimate state of the facts will alone determine the question whether it can be insisted on. The principle upon which losses are settled, when abandonment is validly made, is that the underwriter becomes the proprietor of the subjects abandoned on payment of the sum insured. The effect of an abandonment of the ship is to transfer the ownership to the underwriters, so that whatever freight she may thereafter earn belongs to them; and, although such freight is thereby lost to the original owners, the insurers of the freight are not liable to them for loss in respect of it, because it is lost only by their own act of abandonment, and not by the perils insured against. When goods are so damaged by the perils insured against that they are necessarily sold at any place other than the original destination, they are constructively lost, and the underwriter is liable for their insured value, under deduction of the net proceeds of the sale. But this rule is not applied to goods warranted "free from average unless stranded," if there has been no stranding of the ship,—it being only in that event that the underwriter is responsible for damage to such goods. A constructive loss of freight occurs when the ship is prevented by any peril insured against from completing her voyage, or when the goods on which the freight is to be earned have received such damage that they cannot be conveyed to their destination; but if the ship can proceed with other goods, the freight earned for these must be deducted from the claim for loss.

Particular average.

Partial loss or damage, arising from the perils insured against, is usually, though somewhat loosely, designated by the term "particular average." Under this head are included the damages suffered from the accidental or voluntary stranding of the ship, or by her getting into collision with another vessel, by lightning, fire, hostile attacks, or the violence of the sea under any extraordinary circumstances. Damages to the ship's upper works, sails, spars, and rigging are included under particular average if occasioned by the direct force of the sea; but if caused merely by the force of the wind they are treated as wear and tear, and are not chargeable to the insurers. The loss of anchors and cables parted from by the vessel riding hard, or by the anchor hooking to any object at the bottom, is regarded as wear and tear; and the same rule applies to the repairs of the ship consequent on her becoming leaky through working and straining in a heavy sea. The general principle upon which damages of the nature of particular average are distinguished from those falling under the class of wear and tear is that the former must be caused by the immediate operation of some extraordinary accident, while the latter are only the ordinary incidents of navigation, and as such are not within the scope of the underwriter's contract. But the practical application of this principle is a matter of much nicety, and must usually be left to the judgment of a professional average stater.

In adjusting claims for particular average on ships, certain deductions are made for the difference between "new and old," unless the ship be on her first voyage, either outward or homeward, or the repairs be only temporary. On this footing one-third is deducted from the costs of the materials and labor required for the ship's repairs, excluding, however, the charges for dock dues, surveyor's fees, or similar accessories, which are allowed in full. No deduction is made for anchors (unless in so far as they may be fitted with wood), and the deduction for chain cables is only one-sixth. When a ship has to be recoppered at the expense of the underwriters, the practice is to allow in full the difference of price between old and new metal, to the extent of the weight of the old copper stripped off; and if any sheets have been lost by being rubbed off, the cost of replacing these is further allowed, under deduction of one-third. If the ship has not been stranded, the underwriters are not liable for claims for particular average amounting to less than 3 per cent. on her insured value, independently of the accessory expenses, such as survey fees, etc., which are not taken into account in making up the 3 per cent. Two or more averages occurring in the course of a voyage may, however, be taken together to make up 3 per cent. on the value of the ship, so as to render the insurers liable.

Particular average on goods occurs when they arrive at their port of destination damaged by sea-water, or by its effects in heating or otherwise deteriorating them, although in actual contact only with other portions of the cargo. The amount of compensation recoverable from the insurers for such damage is regulated by comparing the "gross" market price, which the goods would have produced if landed in sound condition, with the actual gross price obtained for them in their damaged state, and by charging to the insurers the same rate of deterioration on the value insured, with the addition of the extra charges specially occasioned by the damage, such as surveys, etc. By this mode of adjustment the assured recovers either more or less than the actual depreciation of the goods, according as the insured value may exceed or fall below the sound market value at the port of destination; but as the latter value generally includes freights, duties and other charges, besides profits, it is in most cases in excess of the insured value, and to the extent of such excess the indemnity of the assured is incomplete. The equity, however, of this mode of adjustment is obvious, when it is considered that the insurer receives his premium only on the value insured, and ought therefore to be liable only in respect of that value, while at the same time the gross market values of the goods in their sound and damaged condition furnish the only true criterion of the actual depreciation, because these are the only values with reference to which, ultimately at least, purchasers could be influenced. It is, however, customary to adjust particular average on a comparison of bonded instead of duty-paid prices in claims for damages to tea, tobacco, coffee, wine and spirits imported into the United Kingdom.

As already indicated, claims for particular average on goods must amount to 3 per cent. or upwards, or in the case of the goods specified in the second clause of the memorandum to 5 per cent. or upwards, otherwise the underwriters will not be liable unless the ship has been stranded; and it is only when there has been a stranding of the ship that the insurers are liable for any such claims on the goods specified in the first clause of the memorandum, or on other goods specially warranted "free of particular average."

General average.

The subject of general average has been treated under the heading AVERAGE (*q. v.*). But it may here be remarked that, in the very recent case of Attwood *v.* Sellar (March, 1880), it has been decided, contrary to the usage of seventy or eighty years, that the expenses of warehousing and reshipping the cargo at a port of refuge, and of the ship in quitting that port, are the subject of general average contribution.

On the general subject of marine insurance the best book of reference is Arnould's *Treatise* (5th edition), which embraces the leading cases decided in the law courts down to a very recent period. Amongst the minor works bearing on the subject may be mentioned Mr. M. Hopkins's *Manual of Marine Insurance*, and Mr. Charles M'Arthur's *Policy of Marine Insurance Popularly Explained*, and especially Mr. R. Lowndes's *Practical Treatise on the law of Marine Insurance* (1881). (J. WA.)

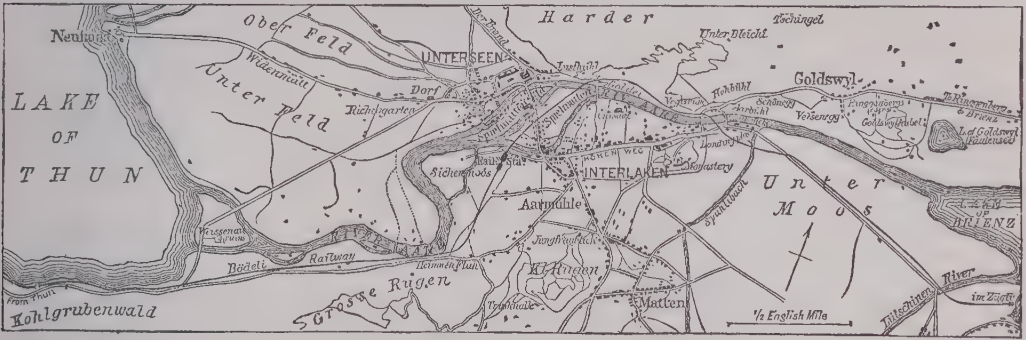
INTERDICT (*interdictum* sc. *officiorum divinorum*), in its full technical sense as an ecclesiastical term, means a sentence by a competent ecclesiastical authority (popes, councils, bishops with chapters) forbidding all administration of the sacraments, celebration of public worship, and use of the burial service. An interdict may be either local, personal, or mixed, according as it applies to a locality, to a particular person or class of persons, or to a particular locality as long as it shall be the residence of a particular person or class of persons. Local interdicts again may be either general or particular; in the latter instance they refer only to particular buildings set apart for religious services. In the writings of Augustine (*Epp.*, 250) there is an indication that something of the nature of an interdict had been attempted in his diocese by a certain bishop Auxilius: the attempt is strongly condemned by Augustine, who disapproved of the plan, as making the innocent suffer along with the guilty. In 869 Hincmar of Laon laid his entire diocese under an interdict, a proceeding for which he was severely censured by Hincmar of Rheims. In the *Chronicle* of Ademar of Limoges (*ad ann.* 994) it is stated that Bishop Alduin introduced there "a new plan for punishing the wickedness of his people; he ordered the churches and monasteries to cease from divine worship and the people to abstain from divine praise, and this he called excommunication" (see Gieseler, *Kirchengesch.* iii. 342, where also the text is given of a proposal to a similar effect made by Odolric, abbot of St. Martial, at the council of Limoges in 1031). It was not until the 11th century that the use of the interdict obtained a recognized place among the means of discipline at the disposal of the Roman hierarchy. Important historical instances of the use of the interdict occur, in the cases of Scotland under Pope Alexander III. in 1181, of France under Innocent III. in 1200, and of England under the same pope in 1209. So far as the interdict is "personal," that is to say, applied to a particular individual, it may be regarded as synonymous with EXCOMMUNICATION (*q.v.*), an ecclesiastical punishment known in one form or another in all churches: the local interdict is quite peculiar to the Church of Rome. It is removed by what is termed "reconciliation."

INTERDICT, in Scotch law, is an order of court pronounced on cause shown for stopping any proceedings complained of as illegal or wrongful. It may be resorted to as a remedy against all encroachments either on property or possession. For the analogous English practice see INJUNCTION.

INTERDICTION, in Scotch law, is a process of restraint applied to prodigals and others who, "from weakness, facility, or profusion, are liable to imposition." It is either voluntary or judicial. Voluntary interdiction is effected by the act of the prodigal himself, who executes a bond obliging himself to do no deed which may affect his estate without the assent of certain persons called the "interdictors." This may be removed by the court of session, by the joint act of the interdictors and the interdicted, and by the number of interdictors being reduced below the number constituting a quorum. Judicial interdiction is imposed by order of the court itself, either moved by an interested party or acting in the exercise of its *nobile officium*, and can only be removed by a similar order. After interdiction duly completed according to law, all deeds done by the interdicted person, so far as they affect or purport to affect his heritable estate, are reducible, unless they have been done with the consent of the interdictors. Interdiction has no effect, however, on movable property.

INTEREST. At English common law an agreement to pay interest is not implied unless in the case of negotiable instruments, when it is supported by mercantile usage. As a general rule therefore debts certain, payable at a specified time, do not carry interest from that time unless there has been an express agreement that they should do so. But when it has been the constant practice of a trade or business to charge interest, or where as between the parties interest has been always charged and paid, a contract to pay interest is implied. It is now provided by 3 & 4 Will. IV. c. 42 that "upon all debts or sums certain payable at a certain time or otherwise, the jury on the trial of any issue or in any inquisition of damages *may* if they shall think fit allow interest to the creditor at a rate not exceeding the current rate of interest, from the time when such debts or sums certain were payable, if such debts or sums be payable by virtue of some written instrument at a certain time; or if payable otherwise, then from the time when demand of payment shall have been made in writing, so as such demand shall give notice to the debtor that interest will be claimed from the date of such demand until the term of payment: provided that interest shall be payable in all cases in which it is now payable by law." Since the abolition of the usury laws by the 17 & 18 Vict. c. 90, a contract stipulating for higher interest than the legal rate of 5 per cent. is no longer illegal. This Act, however, does not affect contracts with pawnbrokers. Compound interest requires to be supported by positive proof that it was agreed to by the parties; an established practice to account in this manner will be evidence of such an agreement. In short, under the present law, any contract that the parties choose to make as to the amount of interest, or the time or manner of payment, will be enforced like any other agreement. When interest is awarded by a court it is generally at the rate of 4 per cent.; under special circumstances 5 per cent. has been allowed.

INTERLAKEN, or **INTERLACHEN**, a Swiss village in the canton and 26 miles south-east of the town of Bern, is situated on the left bank of the Aare in the low-lying district named the Bödeli, between the lakes of Thun and Brienz. The name is strictly applied to the few buildings which occupy the site of the religious houses founded in 1130 and abolished in 1528, but is generally used as including also the Höheweg, a handsome avenue shaded with walnut trees and flanked by hotels and shops, and the village of Aarmühle at its western extremity. The houses are mostly of timber, but the village is lighted with gas, and has an excellent water-supply. The east wing of the Augustinian monastery has been used since 1836 as a hospital for the poor; and the rest of the building together with the castle, added in 1750, is now occupied by Government offices. The nunnery, which was suppressed in 1484, has been converted into a prison. The Kursaal, on the Höheweg, was opened by the hotel-keepers in 1869. Between 150,000 and 200,000 strangers visit Interlaken annually, being attracted by its beautiful situation and fine climate, as well as by its goat's-whey cure. Interlaken is a convenient centre from which to visit the Bernese Oberland, with the Grindelwald and Lauterbrunnen valleys and the Giessbach and Staubbach falls. Population of Interlaken, Aarmühle, and the adjacent Unterseen, in 1880, 4080.



Environs of Interlaken.

INTERNATIONAL. The International Working Men's Association, commonly called the "International," was formed at London in 1864. It was a society of working men of all nations, somewhat like a cosmopolitan trades union, but bearing a still closer resemblance to an international social science association for discussing and furthering the rights of labor. At first moderate in its tone, it soon began to endorse advanced views respecting property and industrial organization. Shortly after it had attained to the height of its power about 1869, it became more and more allied with the most destructive socialism of western Europe. Weakened by internal disunion, and discredited by its approval of the commune at Paris and its alliance with the communial risings in southern Spain, the International died a natural death before it was quite ten years old.

The occasion of the formation of the Internationnl was the visit of some French workmen to the London Exhibition of 1862. This visit had the approval and even the pecuniary support of the emperor, and was warmly commended by some of the leading Parisian organs as a means, not only of acquainting them with the industrial treasures of the exhibition, but of removing from the relations of the two countries the old leaven of international discord and jealousy. In the course of their visit the French delegates were cordially welcomed at an entertainment at the Freemasons' Tavern, where the labor question was discussed, and a desire for the further interchange of ideas expressed. Nothing decisive, however, was done till 1864, when a great public meeting of working men of all nations was held at St. Martin's Hall, at which Professor Beesly presided. Here a provisional committee was appointed to draft the constitution of the new association. In this constitution, which was approved at the first congress held at Geneva in 1866, and in a remarkable address issued by the committee the aim of the International is defined in clear and able terms. It was set forth that, notwithstanding the vast development of industry and the enormous accumulation of national wealth, the lot of the working class was as hard as ever. All the recent revolutions and political reforms had been achieved only in the interest of the middle classes, leaving the position of the working man unimproved. The emancipation of the working men must be the task of the working men themselves. With this view the International was founded, which, while recognizing truth, justice, and morality as the basis of its action, without distinction of creed, nationality, and color, would serve as a common centre for the efforts of working men towards their complete deliverance from the tyranny of capital. A general council having its seat at London was appointed, which was to hold annual congresses and exercise a general control over the affairs of the association, while local societies were allowed free play in all local questions. The working men of a district or trade were to form a section, several sections formed a federation, and all the societies of each nation were if possible to form a national association; but all were to be in communication with the international headquarters.

The first four congresses of the International, held at Geneva (September, 1866), Lausanne (1867), Brussels (1868), and Basel (1869), marked the rapid development of the association. It gained its first triumph in the effectual support of the bronze-workers at Paris during their lock-out in 1867; and it repeatedly gave real help to the English unionists by preventing the importation of cheap labor from the Continent. In the beginning of 1868 one hundred and twenty-two societies of South Germany assembled at Nuremberg declared their adhesion to the International. In 1870 Cameron announced himself as the representative of 800,000 American workmen who had adopted its principles. It soon spread as far east as Poland and Hungary, and it had affiliated societies with journals devoted to its cause in every country of western Europe. The leading organs of the European press became more than interested in its movements; the *Times* published four leaders on the Brussels congress. It was supposed to be concerned in all the revolutionary movements and agitations of Europe, gaining a world historic notoriety as the rallying point of social overthrow and ruin. Its prestige, however, was always based more on the vast possibilities of the cause it represented than on its actual power. Its organization was loose, its financial resources insignificant; the Continental unionists joined it more in the hope of borrowing than of contributing support. At the successive congresses its socialistic tendencies became more and more pronounced; it declared its opposition to private property not only in railways but in mines and the soil, holding that these should revert to the community. Even the principle of inheritance was saved only by a narrow majority. In 1869 Bakunin the Russian socialist or nihilist with his party joined the association, and at once asserted his character as the "apostle of universal destruction."

In 1870 the International resolved to establish itself at the very hearth of the revolutionary movement by holding its annual congress at Paris. This plan was rendered abortive by the Franco-German conflict. That war, however, helped to bring the principles of the association more decidedly before the world. On general grounds, and during the Austro-Prussian struggle of 1866, it had declared its emphatic condemnation of war; and now the societies of France and Germany as well as the general council at London uttered a solemn protest against this renewal of the scourge. Some of its German adherents likewise incurred the wrath of the authorities by venturing to protest against the annexation of Alsace and Lorraine. In this way the International appeared as the champion of a wider principle against the abuse of the principle of nationality.

The relation of the association to the communal rising at Paris in the spring of 1871 has been the subject of much dispute. It is now agreed that the International as such had no part either in originating or conducting it; some of its French members joined it, but only on their individual responsibility. Its complicity after the event is equally clear. After the fall of the commune the general council of London, Karl Marx included, issued a long and trenchant manifesto, approving its action and extolling the "glorious vanquished." From this point the decline and fall of the association is to be dated. The English unionists, intent on more practical concerns at home, never took a deep interest in its proceedings; the German socialists were hindered by law from corporate action; America was too remote. But it found its worst enemies amongst its own friends; the views of Marx and his school were too moderate for the universally subversive principles of Bakunin, and the radical Swiss federation of the Jura led by Guillaume. It came to a rupture at the congress of 1872, held at the Hague, when Bakunin, being outvoted and "excommunicated" by the Marx party, formed a rival International, which found its chief support in Spain and Italy. Wearied of its European contentions and desirous to form a basis of operation in America, the Marx International now transferred the seat of its general council to New York; but it survived just long enough to hold another congress at Geneva in 1874, and then quietly expired. The party of destruction styling themselves "autonomists" had a bloodier history. The programme of this party was to overturn all existing institutions, with the view to reconstructing them on some vague communal basis such as had been tried at Paris in 1871. It endeavored to realize this in the great communal risings in southern Spain in 1873, when its adherents set up their peculiar form of government at Barcelona, Seville, Cadiz, and Cartagena, —at the last-mentioned place also seizing on part of the iron-clad fleet of Spain. As to Paris, they failed in leadership and organization, and were suppressed, though not without difficulty, by the national troops. The "autonomists" lingered on till 1879. At present there is no society that has any claim to the name and prestige of the International. The collapse has thus been complete of an association which once extended from Hungary to San Francisco, and alarmed the minds of men with visions of universal ruin.

INTERNATIONAL LAW is the name now generally given to the rules of conduct accepted as binding *inter se* by the nations—or at all events the civilized nations—of the world. International law as a whole is capable of being very differently interpreted according to the point of view from which it is regarded, and its rules vary infinitely in point of certainty and acceptance. According to the ideas of the leading English school of jurists it is an impropriety to speak of these rules as being laws; they are merely moral principles,—positive, it is true, in the sense that they are recognized in fact, but destitute of the sanctioning force which is the distinguishing quality of law. There is not a word to be said against this criticism considered merely as a verbal criticism, but it may be so used as unduly to depreciate the actual force and effect of the system as a whole. On the other hand, the vast majority of writers on international law have preferred to derive its principles from some transcendental source, such as nature, reason, the Divine will, etc.; and these accordingly have no hesitation in attributing to its rules an intrinsic authority over all the nations of the world. The usage of nations according to this theory is evidence of, but not the origin of, the law. It merely expresses, as Sir R. Phillimore puts it, "the consent of nations to things which are *naturally*, that is, by the law of God, binding upon them." The true position is this—that we find as a fact a number of rules accepted by civilized nations as obligatory in their mutual dealings. These rules no doubt in many cases owe their existence to the prevalence of theories of natural and divine law, but their authority no longer depends on the truth of such theories. The rules are in themselves just and reasonable. Some of them are so precise, so certain, and so universally accepted, that they cannot be distinguished from positive law except by the absence of a determinate legislative source. Many of them are taken up by the municipal laws of different countries, and in so far as they are thus incorporated with positive systems they are in every sense positive laws. But many of the rules of international law are vague, uncertain, and of disputed authority. Some of the rules, for example, relating to capture in war, the law of blockade, and the privileges of ambassadors are so well ascertained and settled that it is hardly conceivable that they should be broken by any civilized state. On other points—*e.g.*, as to what articles should be contraband of war, when a state should interfere with the domestic policy of another—no universally admitted principles can be said to have been established. The substance of international law has been for this reason divided into various sections, according to the degree of certainty which the rules have obtained. Thus one of the most recent writers on this subject, Dr. Woolsey, distinguishes the rights and duties known to the science as (1) those which are deducible from natural *jus*, which no action of a state can begin or terminate, (2) those deducible from the idea of a state, and (3) those which can be created or destroyed by compact, express or tacit. This and similar divisions do not really explain why some of the rules composing what is known as international law are as fixed and certain as rules of conduct can well be, while others are pure matter of controversy. It is simpler to state the fact and to take note that the area of certainty in international law is constantly increasing. For example, the rights of embassies were disputed by England till a recent period; and the rules prohibiting the slave-trade and making privateering illegal are comparatively recent additions to the certainties of international law. To say that such rules as the last, being founded on contract, are therefore of inferior authority to the imperishable principles which pronounce all sovereigns to be equal and independent, and distinguish between just and unjust wars, is absurd.[1]

The theory of international law contemplates the world as divided into independent states. That states are sovereign within their own territories, independent of other states, and equal as between themselves, is a fundamental axiom of the science. Not that all states are regarded as lying within the domain of this law. In modern times at least it has included all the states of the Christian world; but at one time it excluded non-Christian states, and at this moment it would be difficult to say to what extent it covers the relations of such states *inter se* and with the Christian states of Europe and America. There is little doubt, however, that in course of time all the civilized communities of the world will observe substantially the same system of international law.

In the next place international law regards the states of the world as being either in a state of war or in a state of peace. It prescribes rules of conduct to be observed in the mutual dealings of nations which are at peace with each other, and of nations that are at war with each other; and it fixes the rights and duties of belligerent and neutral nations. If peace is the normal state of nations, as jurists sometimes assert, war is the state which has made the largest demands on the science. The rules of international law with regard to war are more voluminous and more certain than those which govern nations in time of peace.

International law, as we now know it, is substantially the creation of civilized Europe in the last three hundred years, but rules of some kind, however meagre, must accompany any state of society in which intercourse, hostile or peaceful, between different communities is common. The great nations of antiquity which have contributed most to the civilization of modern Europe have given least to this branch of that civilization. The history of the Jews furnishes nothing but examples of the total absence of a sense of duty in relation to other nations. The division of the Greek world into a large number of independent communities favored the existence of an Hellenic law of nations, presenting in many points—such as the recognition of common Hellenic customs, religious and political, and of the principle of a balance of power—a parallel to modern international law. The coherence of the Greek communities, however, only intensified the difference between them and all other peoples, and left their relations with them unregulated by any general principles. The *jus feciale* of the earlier Roman law—regulating the formal intercourse between Rome and other nations—is indeed the germ of what might have been a system of pure international law. But the rise of the Roman commonwealth to the mastery of the world rendered a *jus inter gentes* unnecessary and impossible. The fecial law with its college of interpreting priests dwindled into an obsolete collection of formalities no longer supported by the religious feelings of the people. The *jus gentium* of the Romans does indeed play an important part in the history of international law, but as conceived of by the Roman lawyers it was not international, but a body of positive law composed of the elements common to the nations known to them, including Rome itself. Positive international law does not in fact come into existence until the era of Grotius, although usages of international intercourse must at all times have existed. The sanctity attributed to ambassadors, the importance of formal declarations of war, and the good faith to be observed in promises or treaties, would probably be found to be the points of most general recognition.

The connection between Roman and modern international law, through the conceptions of *jus gentium* and *jus naturæ*, has been lucidly traced by Sir Henry Maine in his treatise on *Ancient Law*, and may be briefly noticed here. The postulates of the law of nations—that there is a determinate law of nature, that it is binding on states *inter se*, and that such states are equal—are founded on well-known general principles of the Roman jurists. The ambiguity of the phrase *jus gentium* enabled the early founders of international law to apply the principles of the *jus naturæ* to the conduct of states *inter se* in a way of which there is no example in the Roman law-books. Further, in the Middle Ages the state systems of Europe had arranged themselves on a territorial basis, so that sovereigns were regarded as being the absolute masters of the territory occupied by their people, instead of the chiefs of the people irrespective of territory. They could thus be conceived as "members of a group of Roman proprietors," and the Roman law of property supplied the fundamental principles on which their occupation was in international law understood to be based. The appearance of jurists, dominated by the conceptions of the Roman law, at a time when European arrangements made their application possible, is the true beginning of modern international law. The greatest name is that of Grotius, whose work *De jure Belli et Pacis* was published in 1624. In the first sentence of the prolegomena he defines his subject as the law which obtains between nations or their rulers, whether founded on native or divine ordinance, or custom and tacit consent, which he adds *universim ac certo ordine tractavit hactenus nemo.* There had been earlier workers in the same field. Among these were Francis de Victoria of Salamanca, Suarez, Ayala, and Albericus Gentilis, all of whom flourished in the 16th century. The work of Grotius definitely laid the foundation of the science, which he shaped in imitation of the institutional treatises of Roman law. Among the jurists who followed Grotius, the classical names are those of Puffendorff, Wolff, Vattel, and Bynkershoek. In England Sir Leoline Jenkins and Lord Stowell are the most illustrious of those who have made important contributions to international law. In America Wheaton stands at the head of a school of distinguished jurists, and his *Elements of International Law* is the standard modern treatise on the subject.

Several of the more important heads of international law will have to be noticed separately, and it is only proposed in the present article to state shortly and in outline its leading principles so far as they can be gathered from the most authoritative modern writers. It will be convenient to discuss first the general rules obtaining between nation and nation, and, secondly, the modifications and special rules which are brought into existence by a state of war.

It may be necessary to distinguish here between public international law and what is known as private international law. The latter phrase is applied to those principles which in the ordinary tribunals of a country are used to harmonize the conflict of laws. Where the subject of a foreign state has a claim against the queen or any of the queen's subjects, for which he seeks redress in our courts of law, it may become necessary to recognize and enforce the law of the foreign state and not the law of England. The best illustration of this class of questions is the case of domicile. For many purposes the place in which a man is domiciled, as distinguished both from that in which he lives and the country of which he is a subject, supplies the law applicable to his case. A French subject, domiciled in Scotland, dies in England leaving personal property in England; in such a case the property would be distributed according to the law of Scotland, and not of England or of France. All nations have to provide for such cases, in which the principles of a foreign jurisprudence must be enforced, and have to determine under what conditions and to what extent the tribunal will be required to enforce them. As it happens there is a general agreement among nations on these points; the rule, for example, which makes real property administrable according to the law of the land, and personal property according to the law of the owner's domicile, is universally recognized. So far as this agreement extends, there may be said to be a private international law corresponding to the international system of public law. But in the former we have to deal with true positive law, deriving its authority from the legislature, having no reference to the opinions and practice of nations, and dealing with the rights of individuals. Public international law is of a totally different character, recognizing nations as the only parties, and depending on the agreement of nations as evinced by their opinions and practice. It is with the latter only that we have now to deal.

---

[1] The name "international law" has generally taken the place of the "law of nations," the "law of war and peace," *Jus inter gentes*, etc., used by earlier writers. Bentham suggested international law as the most suitable title.

Independent sovereign states are then the units of international law, and whether a given community is such a state is a question of fact. A community having definite territorial limits within which its own government exercises absolute authority, free from all external control, is the proper type of a state in international law. But the world is not parcelled out among states thus accurately defined. Where a number of states have been united in a permanent confederation, it may be a question whether the group alone is in international law an independent state, or whether each individual member has retained its international independence. The United States of America are an example of the former case; the German confederation until the recent changes was an example of the other. Again, when one state has placed itself under the protection of another, it may be a question whether it has lost or retained its independent status in international law. The proper test, according to Phillimore, is its capacity *de facto* to deal with other states in peace or war, without reference to the protecting state. States which have lost this capacity have been called semi-sovereign states. They have the organization of an independent nation, but are in practice subject to the rule of another state. The Ionian Islands under the English protectorate were in that position, and in the treaty of 1815 they are described as a single free and independent state, under the exclusive protection of Great Britain. A similar character attaches to some of the dependencies of Turkey. On the other hand, a large portion of the surface of the earth is occupied by communities having neither the permanent territorial occupation nor the social coherence of civilized states, yet entering into such relations with them as require the recognition of some system of rules. A further question of the highest importance may arise when a portion of an existing state rises in rebellion and sets up a claim to independence. Here again the question is one of fact. If the rebels have succeeded in establishing a government, it is the right and duty of the nations to recognize the fact, and each nation must judge for itself whether the time for recognition has come. Premature recognition would be regarded as an aid to rebellion inconsistent with the rules of international law. The criterion suggested by practice and authority is whether the old government had ceased to contend in fact against the revolutionary state. But other nations are not bound to wait until the old government has itself recognized the independence of the new. Similar questions arise when the form of government in any country is changed by revolution, or when portions of one state are transferred by conquest to the dominion of another. When the new state of things is established in fact, no matter whether justly or unjustly, it must be recognized by other nations.

With the question of recognition is intimately connected that of non-interference. Premature recognition of a struggling rebellion would be regarded as a breach of the principle of non-intervention, but to recognize the independence of an independent state is part of the same duty as to abstain from interfering with it when it has been established. Writers on international law lay it down as one of the fundamental principles of the science that one state has no right to interfere with the domestic affairs of another. In the formal arrangement of topics it generally appears as one of the necessary consequences flowing from the independence of nations, and Phillimore considers it a self-evident proposition for which it is unnecessary to cite authorities. Nevertheless the practice of nations forbids the doctrine to be stated without limitation. Interference has been sanctioned, according to Phillimore, either in the purely domestic concerns of a nation, or with respect to its foreign relations and territorial acquisitions. The first kind of interference has been justified on the plea of self-defence, as when the decree of the French Convention of 1792, promising aid to all peoples who wished to recover their liberty, was treated as a declaration of war on all existing constitutions. Interference to prevent effusion of blood, or put an end to a state of anarchy from which the interests of other nations necessarily suffer, has also been justified, as when England, France, and Russia interfered between Turkey and its rebellious subjects in 1827. On the whole, the right of intervention has been discredited in international law, and the anomalous condition of the Turkish empire has almost alone in recent times given occasion for its exercise. The ground that reversionary rights of a particular family to the throne of a country justify foreign interference with legislative changes of the succession can no longer be maintained. Nor is it necessary to discuss any such pretended right as that of putting down new Governments which have established themselves by revolution. The same kind of interference is illustrated by the principle of the balance of power which is thus enunciated by Dr. Woolsey—that any European state may be restrained from pursuing plans of acquisitions or making preparations looking towards future acquisitions which are judged to be hazardous to the independence and national existence of its neighbors. According to the same authority, it applies only to European states and their acquisitions in Europe, and does not extend to predominant power on the sea. It is not so much a rule of international law as a maxim of policy which has from time to time united European nations against the dangerous ambitions of one of their number. The "Monroe doctrine" of the United States is of a similar character, being directed against the interference of European states in the affairs of the American continent. The declaration that no European power can be permitted to acquire territory on the American continent is, according to Woolsey, not a principle of the national policy of the United States.

Independent states are said to be equal in international law, because, says Phillimore, it is contrary to the nature of an independent state to be in servitude to another. The proposition negatives any claim of precedence on the part of one or more states in international rank, and asserts that all states equally are entitled to the benefit of international rules. No difference in constitution affects this equality, a republic being the equal of a kingdom, and a kingdom of an empire. Beyond this it can hardly be stretched. It is consistent with conventional inequalities in the reciprocal treatment of nations, and with the habitual recognition in Europe at least of the predominance of the Great Powers. Phillimore deduces from the principle of equality the following rights—(1) the right to protect subjects resident in other countries, (2) the right to recognition, (3) the right to external marks of honor, and (4) the right to enter into treaties. As to the first of these, it may be laid down that a state has cause of complaint if its subjects in foreign countries are denied ordinary justice.

States in relation to the territories occupied by them are treated on the footing of proprietors in law. As between nations each is the absolute owner of its dominions, and the principles applicable to their ownership are taken, as already said, from the Roman law of things. For example, the modes of acquiring territory in international law are said to be four. (1) The first is occupation of land not already occupied (*res nullius*). Mere discovery unaccompanied by beneficial use and occupation will not give a title. (2) The second is prescription or mere possession for a considerable length of time. Jurists on the whole are agreed in admitting this title, although they refrain from attempting to fix a period of prescription. These have been called original modes of acquisition, while secondary or derivative modes are (3) gift, purchase, or treaty, and (4) conquest in war. With reference to these distinctions it may be observed that the overruling consideration is actual possession as a matter of fact. Sovereignty exercised *de facto* over any territory makes it the territory of the sovereign state. This is a deduction of what has already been said on the subject of recognition, and the modes of acquisition here described would only be appealed to in default of such unequivocal possession. In former times a bull of the pope has been set up as a title, *e.g.*, the famous bull of Alexander VI. granting to Spain all lands west of a north-and-south line drawn a hundred leagues west of the Azores. No such mode of acquisition would now be recognized even by Catholic states. In modern times the acquisition of territory is to some extent governed by the wishes of the inhabitants. As an abstract principle of international justice, the transfer of territory from one sovereignty to another should be with the consent of the people. But this is not yet a recognized rule of international law, although in many recent cases of acquisition of new territory a certain amount of deference has been paid to it. In the treaty of Prague (1866), in the union of the Neapolitan provinces to the kingdom of Italy, and in the union of Savoy and Nice to France, the rights of the inhabitants to decide on the proposed transfers are expressly reserved. A recent and more painful instance is the annexation of the Transvaal by England under an order in council which authorized the measure if it should appear to be agreeable to the legislature or a sufficient portion of the inhabitants. It is now clear that no such assent was given by the people, while the acting Government of the republic firmly protested against the annexation.

The territory of a state includes all the lands and inland waters within its boundaries, the mouths of rivers, bays, and estuaries, and the sea to the distance of a marine league along the coast. By a fiction vessels on the high seas, and public vessels everywhere, are treated as part of the territory of the state to which they belong. The high seas are no nation's property,—although in the earlier stages of international law exclusive pretensions have been set up to particular seas, as by Spain to the Pacific, England to the seas around Great Britain, and Russia to the North Pacific.

Formal intercourse between nations is carried on under well-ascertained rules. Omitting mere ceremonial regulations, we may notice specially the position assigned by the law of nations to ambassadors. These are the highest class of diplomatic agents, and according to the universal modern practice they are permanently attached to the foreign court to which they are accredited. The earlier practice (*e.g.*, before the Reformation) favored the appointment of special ambassadors for particular business. The office of ambassador, whether permanent or temporary, has at all times been clothed with a character of peculiar sanctity. His privileges during residence at a foreign court may be summed up in the statement that himself, his house, his property, and his household are exempt from the foreign jurisdiction. Like a ship of war in foreign waters, the embassy is exterritorial—supposed by fiction of law to be part of the sovereign's dominions. The ambassador therefore is not liable to prosecution in the criminal nor to suit in the civil courts. His official residence is free from the local jurisdiction; but it is no longer an asylum, and a criminal taking refuge there may be seized by the local authority if not delivered up by the ambassador. Ambassadors are further relieved from taxation on goods imported for their own use, a privilege which has not unfrequently been abused. An ambassador is entitled to freedom of worship, whether his religion be tolerated by the local government or not. The suite of an ambassador down to his domestic servants are also exempt from the local jurisdiction. The household may in some respects be likened to a separate community under the sovereignty of the ambassador. But it is only in minor affairs that his power to actually execute criminal justice on his own servants would now be recognized. The proper course for him to adopt in a serious charge would be to send the accused home to be tried. The privileges of an ambassador and his suite, it should be added, apply only so far as they do not act beyond the limits of their legatorial character,—*e.g.*, as merchants, trustees, and so on. Exceptional crimes committed by an ambassador do not destroy his character or rights,—at least according to the general consensus of modern authorities, although English lawyers have argued that a crime *contra jus gentium* destroyed the ambassadorial character. Besides ambassadors, two inferior grades of foreign ministers are recognized, viz., (1) envoys, ministers, or others accredited to sovereigns, and (2) chargés d'affaires accredited to ministers charged with foreign affairs. These three grades of diplomatic rank were settled by the congress of Vienna (1815) to avoid the embarrassment arising from claims of precedence. Consuls are merely local agents of a foreign Government, for certain limited purposes, such as facilitating and recording legal transactions affecting the subjects of the state they represent, and assisting them in obtaining their legal rights. They are appointed with the permission (*exequatur*) of the country in which they are to act. They have no immunity from local jurisdiction except under special arrangements. In non-Christian countries the consuls representing Christian states have more extensive functions. In Turkey and the Mahometan countries of the Levant they exercise generally an exclusive criminal and civil jurisdiction over their countrymen.

The contracts made by states with each other are in international law treated according to the general principles of the law of contracts (see TREATIES). Under the modern practice rules of private law affecting foreigners are in many cases settled by treaty on the basis of reciprocity, *e. g.*, extradition, copyright, etc.

Hitherto we have considered nations as in a state of peace. War introduces an entirely new order of rules, applying either between the belligerents themselves or between the belligerents and neutral states. To the question whether a given war be just or unjust international law has no answer to give, or only a formal one. Any war undertaken in defence of the rights which have been already described might be called a just, and any war undertaken in violation of them might be called an unjust war. The justice or injustice of any war is really a question of morality, and in proportion as international law has escaped from the merely ethical region it has abandoned the attempt to decide this question. It figures largely in Grotius, as compared with later writers, and more largely in the speculative than in the positive jurists. One condition of the legality of a war, that of a formal declaration, borrowed from Roman practice by Grotius and some of his followers, has ceased to be of any importance, although some publication of the fact of war is considered necessary in fairness to neutrals. But all wars are legal in international law—that is, they are governed by the rules of the law of war—except wars levied by pirates or piratical communities. The part played by international law has been not to prevent but to regulate warfare. Nations have arrived at a tolerable degree of unanimity as to how wars ought to be conducted, and the result is a certain and progressive law of war. They are far from having arrived at any understanding as to the conditions under which war ought to be allowed; when they are within sight of any such understanding, it will be time enough to talk about a war being just or unjust in international law.

The absence of any legal standard of the justice of a war only adds to the importance of the moral question. There being no law of nations to restrain the warlike ambition of nations, as there is to restrain their passions when war has begun, the purely moral restraints become all-important. Among these it might not be worth while to reckon the kind of selfishness which counts the cost of a campaign against a powerful enemy. But a generous horror of war for its own sake may safely be pronounced to be, in spite of recent events, a growing public sentiment, particularly in the English-speaking people of both worlds. There is no English or American statesman who would not at least do lip-service to the principle that an avoidable war is a public crime. Some of them have done more. The great experiment in international arbitration between England and America in 1871 was more glorious to its promoters, and will be more fruitful of benefit to mankind, than fifty victorious campaigns. It is through the establishment of the principle of arbitration that we may ultimately hope to see the question of justice or injustice in war take its place among the topics of international law.

Short of war, certain preliminary measures of hostility are recognized. These are—"embargo," or the seizure in port of vessels belonging to a foreign nation with which we have a difference, in order to bring it to justice; "retorsion," or retaliating on the foreign nation or its subjects, by similar injuries to those inflicted on us; and "reprisals," or the seizure of foreign property in retaliation for wrongs done to us. These are now of little importance. The right of "pacific blockade," *i.e.*, the blockade of ports belonging to a nation with which we profess not to be at war, has been asserted in a few doubtful instances, but such interference ought to be treated as an act of war.

A state of war transforms the nations engaged into two hostile camps, every man in either being the enemy of all in the other, and entitled to slay and capture as best he can. Such at least is the "natural" theory of war, which international law has reduced to much smaller proportions. First, hostile acts are strictly reserved for the soldiers or others acting under direct public authority; non-combatants are to be regarded as neutrals so far as actual warfare is concerned; they must abstain from hostile acts, and they must be left unharmed by the enemy. Property taken in war belongs to the state, not to the individual captor; and, on the other hand, subject to modifications to be pointed out hereafter, only the property of the state and not private property should be liable to capture. War is thus reduced to an open armed strife between two states carried on by means of a definite and unmistakable set of agents, viz., the fleets and armies. That the non-combatant portions of the two communities should remain as though they were in a state of peace is the principle towards which international law appears to be tending. The movement against privateering is an illustration of this tendency. In wars carried on by land, non-combatants are as far as possible kept out of the sphere of operations,—persons only under public military command being regarded as combatants. In naval warfare it has long been recognized as a valid mode of conducting hostilities to grant "letters of marque" to private vessels, owned, manned, and officered by private persons. Its analogy on land would be a roving commission to private gangs of freebooters. These letters commission the privateers to prey upon the commerce of the hostile nation, the reward for their services being the plunder they may chance to gain. The privateer may belong to a neutral nation or to the nation granting the commission. The practice is defended on the ground that it enables a power having weak naval resources to cope with a great naval power on sudden emergencies. On the other hand the loose discipline of privateer crews, and the fact that their object is simply plunder, are serious evils. The treaty of Paris of 1856 contains the famous declaration that "privateering is and remains abolished," and the adhesion of the United States to this principle would go far to make the practice illegal by the law of nations. Hitherto they have declined, preferring the more comprehensive policy of prohibiting the seizure of private property of all kinds by ships of war. This point conceded, the United States would assent to the abolition of privateering.

Contracts entered into between the subjects of hostile states are void. Rights already created by contracts entered into before the war are not destroyed, but the remedy is suspended, an alien enemy having no redress in courts of law. All commercial intercourse between the two peoples is interdicted, according to the maxim that there cannot be at the same time "a war for arms and a peace for commerce." Partnerships between a citizen and an alien enemy existing before the war are *ipso facto* extinguished by the war. All nations, in fact, are agreed in pronouncing illegal during a time of war the ordinary commercial intercourse which prevails between them in time of peace. The principle extends to giving one of two allies a right to prohibit intercourse carried on with or without license by the subjects of the other with the common enemy. Contracts for the ransom of captured property are valid by the law of nations, but may be and sometimes are restricted by the provisions of a municipal law. And a state may of course grant special licenses to its own subjects to trade with the enemy.

The effect of war on the persons and property of alien enemies within the dominions of the state, and on debts due to them by the state or its subjects before the war, has been greatly softened in modern practice. In strict theory the debts and property would be liable to confiscation, and the persons themselves to detention as prisoners of war. Such is the rule laid down by Bynkershoek, but later writers have held that the guarantees to a contrary effect contained in commercial treaties and even in voluntary declarations by belligerent powers have altered the law of nations on this point. This question was expressly decided in an important American case (Brown *v.* The United States), in which the supreme court held that the ancient rule still remained unimpaired as a right recognized by the law of nations, however much it might have been mitigated in practice. In that case, however, its exercise was held to require a special Act of Congress. The confiscation of debts and the confiscation of property seem to stand on the same footing, and in both cases it may be said that the law of nations has not yet formally recognized the rule established by universal practice. The act of the Confederate Congress in 1861, confiscating all property and debts (except public debts) due to an alien enemy, may be taken as the exception which proves the rule. It has been unequivocally condemned, and was vigorously protested against at the time by Earl Russell as a violation of the spirit of modern law. Even the Confederate Act did not profess to confiscate public debts, and it may be taken as the settled rule of law that no state is justified in repudiating its own public obligations to the subjects of a state with which it may be at war.

The laws and usages of actual war exhibit the same tendency to substitute a milder and more humane code for the unrestrained license of earlier times. The inspiring idea of Grotius was in fact to introduce the spirit of law into the conduct of hostilities, to enforce the principle that there was a lawful as well as an unlawful way of waging war. Between the time of Grotius and our own the sphere of law in war has greatly widened. No nation claiming to be civilized would now venture to conduct a campaign otherwise than, according to the rules of civilized warfare, unless against savages from whom no reciprocal treatment is to be expected, or rebels to whom they refuse the status of belligerents. Besides the influence of international law systematically studied as a science, and the general growth of humaner modes of life and action, a specific cause of this improvement in the law of war is the fact that battle is now for the most part the business of professional soldiers scientifically equipped, and accustomed to stringent discipline. For the best historical view of this interesting subject we may refer to Mr. Montague Bernard's paper "On the Growth of Laws and Usages of War," in the volume of *Oxford Essays* for 1856.

The actual laws and usages of civilized warfare can scarcely be brought within the scope of the present article, but we may refer to a summary of them contained in the project of an international declaration submitted to the Brussels conference of 1874. The conference did not result in any international convention, and England firmly repudiated portions of the declaration which appeared to be calculated to "facilitate aggressive wars, and to paralyze the patriotic efforts of an invaded people." But on the whole this document, although not accepted into the legislation of nations, expresses their general sense on most of the points with which it deals. It lays down rules with regard to (1) the occupation of a hostile country by military force, (2) the distinction between combatants and non-combatants, (3) the means of injuring an enemy, (4) sieges and bombardments, (5) spies, (6) prisoners of war, (7) sick and wounded, (8) private individuals and private property, (9) contributions and requisitions, (10) flags of truce, (11) capitulations, (12) armistices, (13) belligerents interned or wounded treated in neutral territory. Under the first, second, eighth, and ninth heads the effects of war are restricted to the property of the state and its recognized army, although the necessity of military organization in order to entitle combatants to the rights of war is laid down too stringently. Private property must be respected, and pillage is expressly forbidden, but on the other hand an army of occupation has a right to seize all the personal property of the state which is likely to be of use in war, including any kind of munitions of war although belonging to private individuals or companies, The occupying state is to consider itself in the light of an administrator and usufructuary of the public buildings, etc., of the hostile state. Contributions and requisitions may be imposed on the inhabitants, for which receipts must be given. Under the third head there are forbidden the use of poison or poisoned weapons, murder by treachery or murder of a disarmed enemy, declaration of "no quarter," projectiles causing unnecessary suffering or prohibited by the declaration of St. Petersburg, 1818, abuse of the flag of truce, and unnecessary destruction of enemy's property; but *ruses de guerre* are permitted. Spies (who collect information on false pretences or secretly in territory occupied by the enemy) shall when captured be tried and treated according to the law of the army which captures them. The bearer of a flag of truce is inviolable unless he abuse his position, but a commander is not bound to receive a flag of truce. Treatment of the wounded is regulated by the Geneva Convention of 1864, and such modifications thereof as may from time to time be made. The English reader will find a copy of the Brussels project in Boyd's edition of Wheaton's *International Law*. The Geneva Convention, to which reference is here made, was an international compact between the European states, establishing the neutrality of ambulances and military hospitals, and of all persons engaged in the service thereof, as well as of inhabitants of the country bringing help to the wounded. The hospitals, etc., shall bear a distinctive flag (red cross on white ground), and badges similarly distinguished shall be allowed for individuals entitled to the benefits of neutrality. The St. Petersburg declaration renounces for the contracting parties in case of war among themselves the use of "any projectile of a weight below 400 grammes, which is either explosive or charged with fulminating or inflammable substances."

War by land is necessarily carried on within the territory of one or other of the belligerents, and generally in the midst of surroundings devoted to the permanent works of civilization and peace. Naval warfare is a duel between two sets of "floating fortresses," on an element which is no nation's exclusive property, and in no nation's continuous possession. This is the principal reason for the superior humanity characterizing the rule of war on land, where the license of primitive warfare would be infinitely more disastrous than it would be at sea. Another reason why the law of the sea retains so much of its original severity is that its rules have been developed under the influence of a regular court and a professional bar, and have acquired the fixed and inelastic character peculiar to positive law. The toleration of privateering already noticed is an example of the difference between the two systems, and the practice of bombarding seaports to enforce contributions is another. The liability of private property to capture is, however, the most important point of difference. The public vessels of the enemy are of course the natural prey of our own. The private property of the enemy may be contained either in private vessels of his own or in the ships of neutral powers, and we may add for the sake of convenience a third case, where the private vessels of the enemy carry goods belonging to neutral owners. In the last case, when the hostile vessel has been captured, the neutral property is not affected thereby—*enemy ship* does not make *enemy goods*. In the second case the treaty of Paris has promulgated the rule that *free ship* makes *free goods*, which may now be regarded as the established modern rule. In the first case ship and cargo alike are the prey of our vessels of war. In the result, therefore, we may capture the enemy's ships and the enemy's property on board his own ships, but we must spare neutral vessels and all the goods therein, whether belonging to enemies or neutrals, and neutral goods when found on board the enemy's vessels. There is, however, a manifest tendency in international opinion to withdraw private vessels and private property lawfully used altogether from the sphere of warlike operations. The law of capture by sea is further considered under the heading PRIZE.

It remains to speak of the right of neutrals, and their obligations to the belligerents. The neutral nation is to be regarded as the friend of both belligerents, and is bound to treat both of them alike. Jurists distinguish between "strict" or "ordinary" neutrality, and "imperfect" neutrality, in which certain advantages are allowed to both belligerents, or in which advantages are granted to one of the belligerents only under a prior treaty, which the other belligerent does not choose to consider a *casus belli*. The "perpetual" neutrality of Belgium and Switzerland secured by treaties binds those states to abstain from taking part in any war arising between their neighbors. The combination of several northern powers to enforce by arms certain alleged rights of neutrals against the claims of belligerents in 1780 and 1800 has been termed an "armed neutrality."

Neutral states are entitled to prohibit all belligerent operations within their territory,—using that phrase in the enlarged sense it bears in international law. They may prevent the passage of fleets or armies through those portions of the sea or land over which their jurisdiction extends. Hostilities carried on within neutral territory are unlawful, and captures effected thereby are void. The rule is indisputable, but its application to warfare by sea has not been free from controversy. A capture made outside the neutral territory by the boats of a ship lying within the neutral territory has been held to imply an illegal use of that territory for purposes of war. On the other hand, a capture begun outside, but consummated within the neutral territory, is also, notwithstanding the theory set up by Bynkershoek, entirely illegal. It is in fact as much the duty as the right of the neutral state to insist on these prohibitions, as the omission to do so in any case might give an advantage to one belligerent over the other inconsistent with true neutrality. The exemption of neutral property everywhere from the operation of war has been already noticed. The impartiality which it is the duty of the neutral to observe towards the belligerents has been summed up by Vattel in two propositions cited with approval by Wheaton:—(1) that no assistance should be given to either party in matters relating to war unless under some pre-existing stipulation;[1] (2) that in matters not relating to war the neutral should not refuse to one belligerent "merely because he is at war with the other what she grants to that other." The obligation of impartiality extends to prohibiting the use of the neutral territory for the purpose of fitting out warlike expeditions, equipping vessels, and enlisting men. The right and duty of neutral nations in this respect were first recognized and enforced by the United States, long the chief representative and champion of neutral rights. An Act of Congress passed in 1794, re-enacted 1818, makes it a misdemeanor for "any person within the jurisdiction of the United States to augment the force of any armed vessel belonging to one foreign power at war with another power with whom they are at peace, or to prepare any military expedition against the territories of any foreign nations with whom they are at peace, or to hire or enlist troops or seamen for foreign military or naval service, or to be concerned in fitting out any vessel to cruise or commit hostilities in foreign service, etc." The same principles inspire the English Foreign Enlistment Acts which have been pronounced by the well-known writer "Historicus"[2] to be a transcript of the American law. The 59 Geo. III. c. 69 was the first Act known by this title; the statute now in force is the Foreign Enlistment Act, 1870 (33 & 34 Vict. c. 90). These Acts are correctly described as municipal statutes, based indeed on international law, but intended for the protection of the neutral state rather than the belligerents.[3] The purely international obligations of the belligerent have been recently the subject of protracted discussions between England and America, arising out of the depredations committed by Confederate cruisers on American commerce. The treaty of Washington, 1871, by which all these questions were referred to arbitration, directed the arbitrator to apply to them not only the rules of the law of nations but three new rules, which England at least could not admit as being in force when the claims arose, but which she acceded to as an evidence of her desire to strengthen friendly relations with the United States. Both parties agreed to abide by these principles in future, and to invite other nations to accede to them. The rules were that a neutral government is bound—(1) to use due diligence to prevent the fitting out, arming, or equipping within its jurisdiction of any vessel which it has reasonable ground to believe is intended to cruise or to carry on war against a power with which it is at peace, and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessel having been adapted in whole or in part within such jurisdiction to warlike use; (2) not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other, or for the purpose of renewal or augmentation of military supplies or arms or the recruitment of men; and (3) to exercise due diligence in its own ports and waters, and as to all persons within its jurisdiction, to prevent any violation of the foregoing obligations and duties.

These rules, which we believe to be substantially just, have been unduly discredited in England, partly by the result of the arbitration, which was in favor of the United States, partly by the fact that they were from the point of view of English opinion *ex post facto* rules, and that the words defining liability ("due diligence") were vague and open to unforeseen constructions,—for example, the construction actually adopted by the Geneva tribunal that due diligence ought to be exercised in proportion to the belligerent's risk of suffering from any failure of the neutral to fulfil his obligations.[4] One important principle, to some extent challenged in these controversies, is established beyond dispute. Whatever the obligations of a neutral in any given case may be, failure to fulfil them is not excused either by defects of the municipal law or by successful evasions of that law. The neutral state ought to make its laws conformable to its international duties, and to compel its subjects to obey them. If it fails in either respect, and injury to belligerents is the consequence, it is answerable under the law of nations.

So far we have been dealing with the rights and duties of neutral *states.* Neutral commerce in times of war is subject to restrictions which affect individuals rather than states, such as the rules relating to blockade and contraband of war.

Pirates and savages or uncivilized tribes have been mentioned as excluded from the benefits of international law. The municipal law of most countries assumes jurisdiction over the former wherever they may be found (see PIRACY). With regard to the latter, it cannot be said that civilized nations have observed any rule of law or morality whatsoever in their dealings with them. The overflowing population of European nations has been compelled to seek an outlet in regions occupied by men in a low state of civilization, neither capable nor desirous of making a beneficial use of them. It is not to be pretended for a moment that the Europeans were bound to leave the continent of America to its original Indians, for even civilized communities are not permitted to claim dominion over territory which they do not really occupy. But the early European settlers founded their claims on some authority, generally that of their own sovereigns, which recognized no right whatever in the original occupants. They were described in patent deeds as "heathens and infidels," and a color of religious duty was thus imparted to the most barefaced schemes of spoliation. Wheaton cites the authority given by Henry VII. to Cabot and by Queen Elizabeth to Sir Humphrey Gilbert to seek out foreign and barbarous lands "not actually possessed of any Christian prince or people," and to hold, occupy, and enjoy the same. Vattel, who strongly insists upon the right of civilized people to reduce the ineffective occupation of savages to the narrowest possible limits, warmly commends the conduct of William Penn and the English Quakers in purchasing from its savage occupants the country they wished to inhabit. The colonizing nations, says Wheaton, were agreed in one thing, viz., in "almost entirely disregarding the right of the native inhabitants." Settlements of this kind are not now made from European countries, and public opinion would no longer sanction the pretensions on which they were based. But between the European settlements already established and the native tribes by which they are surrounded the same disregard of the rights of the weaker party is only too common. So far as England is concerned, the temptations of her colonists to commit injustice in their dealings with inferior races are counterbalanced by an active public opinion at home. In the conduct of hostilities against savages, civilized troops would not be regarded as bound by the international law of war; and it is difficult to conceive of any restraint other than that of their own sense of decency and humanity. In conflicts between civilized communities the employment of savages on either side is condemned for this very reason. In self-defence the troops opposed to them must resort to practices condemned by the opinion of the civilized world.

---

[1] Phillimore considers that such stipulations made in time of peace are wrongful and incompatible with sound neutrality. The fulfilment of them would be an attempt to do the act of a belligerent and yet claim the immunity of a neutral.

[4] See Montague Bernard's *British Neutrality.*

The main object of this article has been to exhibit the law of nations as much as possible in the form of a positive system of rules binding on states *inter se*, to assimilate the treatment of the subject to a statement of the ordinary rules of positive law. Many topics have therefore been omitted which are discussed at length in treatises on international law. It is not always possible to say where international law begins and international morality ends, but it is of the highest importance to mark the distinction. The former, taken broadly, means the rules of conduct that the nations of the civilized world admit and insist upon as a matter of course, and the fact that there are such rules is the central fact of the whole subject. Every addition to them is a positive good to the whole world, and such additions are for the most part to be traced to the reasonings of private thinkers. But to treat principles supported only by the authority of jurists, however distinguished, as of equal validity with those which have been adopted by the universal practice of nations is to weaken the one without strengthening the other. It should be said, moreover, that the systematic study of international law with a view to its improvement by jurists of all countries organized in societies like the *Institut de Droit International* at once tends to mature opinion and to give it an immediate hold on the practice of nations.

Among the purely speculative questions connected with international law two deserve special notice on account of the extent to which they have engaged the sympathies at least of the best minds in every age. One is the project for a perpetual peace, the other is the more immediately practical proposal to reduce the law of nations to a written code. With the former the names of Bentham and of Kant are associated. Bentham's plan is a congress of deputies, two from each state, which should determine international disputes, and the decrees of which should be enforced against any state that might resist them by the combined power of the rest. As a preliminary condition he requires the reduction of military establishments and the abandonment by European nations of their colonies. Kant proposes a confederation of states, all under a republican constitution, and acting in international affairs through congresses to be held from time to time. An account of these and other projects of the same kind will be found in Wheaton's *History of the Law of Nations.* Codification would effect for the law of nations, as a whole, what has already been done for portions of it by the St. Petersburg and Geneva Conventions, and even by the treaties of Paris and Washington. All states are alike interested in ascertaining the rules to which they have assented in general terms. The work has already been to a great extent performed by private associations, and what is wanted is the formal ratification of their labors by the Governments of the world.

The following are the most authoritative modern works on International Law:—Henry Wheaton's *Elements of International Law* (8th American edition published in 1866 with notes by R. H. Dana, jun.; an English edition appeared in 1880); Sir Robert Phillimore's *Commentaries on International Law*, in 4 vols. (a very complete and elaborate work); Sir Travers Twiss's *Law of Nations*, 2 vols.; and Heffter's *Das Europäische Völkerrecht der Gegenwart.* To these may be added the less important treatises of Richard Wildman, William Oke Manning, and H. W. Halleck (American). Useful elementary works are Chancellor Kent's *Commentary*, which has been edited in England by Dr. J. T. Abdy; T. D. Woolsey's *Introduction to the Study of International Law;* and W. E. Hall's *International Law.* The history of the law of nations has been treated by Wheaton, Ward K. von Mohl, and F. Laurent. (E. R.)

INTERPLEADER, in English law, is the form of action used when a person is sued at law for the recovery of money or goods wherein he has no interest, and which are also claimed of him by some third party. Originally the only relief available to the possessor against such adverse claims was by means of a bill of interpleader in equity. The Interpleader Act, 1 & 2 Will. IV. c. 58, enabled the defendant in such cases, on application to the court, to have the original action stayed and converted into a trial between the two claimants. The Common Law Procedure Act of 1860 further extended the power of the common law courts in interpleader; and the Judicature Act, 1875, enacts that the practice and procedure under these two statutes shall apply to all divisions of the high court of justice. The Judicature Act also extends the remedy of interpleader to a debtor or other person liable in respect of a debt alleged to be assigned, when the assignment is disputed. Interpleader is the equivalent of multiplepoinding in Scotch law.

INTESTACY. In dealing with the property of a person who dies without making a will, the law of England distinguishes sharply between his real and his personal estate. The devolution of the former is regulated by the rules of INHERITANCE (*q. v.*). The destination of the latter is marked out by the Statute of Distributions. The proper conditions of a testamentary disposition of property will be found under the heading WILL.

The distribution of an intestate's personal estate is carried out under the authority of administrators, whose duties are generally the same as those of executors under a will. Administration was until quite recently a matter cognizable by the ecclesiastical courts, and the ordinary was in fact the administrator until the passing of the 31 Edw. III. st. i. c. 11. An earlier statute (Westminster 2) directed against the abuses of the system required the ordinary, instead of applying the residue of the estate to "pious uses," to pay the debts of the intestate. The Act of Edward III. went further in providing that "in case where a man dieth intestate, the ordinaries shall depute of the next and most lawful friends of the dead person intestate to administer his goods," with power to sue for debts due to the deceased, and under obligation to pay debts due by him, and to answer to the ordinary like executors in the case of testament. Administrators remained on this footing of deputies appointed by the ordinary until the Probate Act transferred the jurisdiction in administration of the ecclesiastical courts to the new court of probate.

The courts of law having held that by the grant of administration the authority of the ecclesiastical courts was exhausted, the administrator became entitled to the privilege, similar to that formerly enjoyed by the ordinary, of dealing as he pleased with the residue of the estate. The next of kin of the same degree of relationship with the deceased were thus aggrieved by the preference of the administrator, and it was to remedy this grievance that the Statute of Distributions (22 and 23 Charles II. c. 10) was passed. It empowered the ordinary to take a bond from the administrator binding him to make a fair and complete distribution of the estates among the next of kin. Such distribution is to be in the following manner:—one-third to the wife of the intestate, and all the residue by equal portions to and amongst the children, and their representatives if any of such children be dead, exclusive of children who shall have any estate by the settlement of the intestate, or shall be advanced by the intestate in his lifetime by portions equal to the shares allotted to the other children under the distribution. If such advancement should be less than the share of the other children in distribution, then it shall be made equal thereto. But the "heir-at-law, notwithstanding any land that he shall have by descent or otherwise from the intestate, is to have an equal part in distribution with the rest of the children" (§ 5). By § 6, if there be no children nor any legal representatives of children, one moiety of the estate is to be allotted to the wife of the intestate, the residue "to be distributed equally to any of the next of kindred of the intestate who are equal in degree and those who legally represent them." By § 7 there shall "be no representation admitted among collaterals after brothers' and sisters' children; and in case there be no wife, then all the said estate to be distributed equally to and among the children; and in case there be no child, then to the next of kindred in equal degree of or unto the intestate and their legal representatives as aforesaid, and in no other manner whatsoever." For the protection of creditors it is enacted that there shall be no distribution till a full year after the intestate's death, and if any debts should be discovered after distribution, the persons sharing the estate shall refund the amount of the same ratably. Finally, by § 4 it is provided that nothing in the Act shall prejudice the customs of London, York, and other places having customable rules of succession; but these have been since abolished.

With reference to the above rules the following points may be observed:—(1) The husband's absolute right to administer his wife's estate is not affected by the Act. This was made clear by a later Act of the same reign (29 Charles II. c. 3). Administration is now granted to the representatives of the husband, where he has died without taking out administration to his wife, unless it can be shown that the wife's next of kin are beneficially interested. (2) The widow, in the event of there being no children or next of kin, takes only her half. The other half goes to the crown. (3) The child or children take equally two-thirds if the widow be alive, and the whole if she be dead. If the children of the intestate be all dead, the grandchildren will take equally amongst themselves as next of kin; if there be neither child nor grandchild alive, the great-grandchildren would likewise take equally as a class (*per capita*). But if some of the children be alive, some dead leaving issue, the children of a deceased child take their father's share (*per stirpes*). Thus, for example, the ten children of a deceased son would only take between them their father's share if any brother or sister of their father were alive; if not, they would share equally with the other grandchildren. (4) The next of kin must be ascertained according to the rules of consanguinity, which are the same in English as in the civil law. Degree is calculated from the intestate, through the common ancestor, if any, to the kindred. Thus from son to father is one degree, to grandfather two degrees, to brother two degrees, to uncle three degrees, and so on. The statute ordains distribution to be made "to the next of kindred in equal degrees *pro suo cuique jure*, according to the laws in such cases and the rules and limitations hereafter set down." Equality in degree is therefore not in all cases accompanied by equality in rights of succession. Neglecting the cases of wife and children already noticed, the father excludes all other next of kin. So would a mother, in default of a father surviving, but the Act 1 James II. c. 17 enacted that in such a case the brothers and sisters of the intestate should share equally with the mother. The language both of this and of the principal statute is very inapt, and has given rise to complicated questions of interpretation. In the absence of brothers or sisters and their representatives, the mother in the case supposed would take the whole. Mothers-in-law and stepmothers are not within the rules of consanguinity. As between a brother and a grandfather who are both in the second degree, preference is given to the brother; but a grandfather, being in the second degree, will exclude an uncle, who is in the third. An uncle and a nephew, both being in the third degree, take together. Brothers or sisters of the half blood take equally with brothers and sisters of the whole blood. The rule which prohibits representations after brothers' and sisters' children would, in a case where the next of kin were uncles or nephews, wholly exclude the children of a deceased uncle or nephew. Also, as between the son of a brother and the grandson of a brother, the latter would not be admitted by representation. Where a brother and the children of a deceased brother are the next of kin, they will take *per stirpes*, *i.e.*, the brother will take one half, and the children of the other brother will take the other half between them. When the next of kin are all children of the deceased brothers or sisters, they will take equally *per capita*. Subject to these modifications, the personal estate will be divided equally among the next of kin of equal degree, *e.g.*, great-grandfathers would share with uncles or aunts, as being in the third degree. Failing next of kin, under these rules, the estate goes to the crown as *ultimus hæres*, a result which is more likely to happen in the case of illegitimate persons than in any other.

Personal or movable property takes its legal character from the domicile of the owner, and the distribution of an intestate's goods is therefore regulated by the law of the country in which the intestate was domiciled. A domiciled Scotchman, for example, dies intestate in England, leaving personal property in England; the administrator appointed by the court of probate will be bound to distribute the estate according to the Scotch rules of succession.

In the law of Scotland the free movable estate of the intestate is divided amongst the nearest of kin, the full blood excluding the half blood, and neither mother nor maternal relations being originally admitted. The heir of the heritable property if one of the next of kin must collate with the next of kin if he wishes to share in the movables. Proximity of kin is reckoned in the same order as in the case of inheritance. The Intestate Movable Succession Act, 1855, among other changes, allows the issue of a predeceasing next of kin to come in the place of their parent in succession to an intestate, gives the father of an intestate dying without issue one-half of the movable estate in preference to brothers and sisters, and to the mother if the father be dead a similar preference to the extent of one-third, and admits brothers and sisters uterine in the absence of brothers and sisters german or consanguinean.

In the United States the English Statute of Distribution has been taken as the basis of the law for the distribution of personal property in intestacy, and its principles have been applied to real property also. "In a majority of the States the descent of real and personal property is to the same persons and in the same proportions, and the regulation is the same in substance as the English Statute of Distribution. In Georgia the real and personal estate of the intestate is considered as altogether of the same nature and upon the same footing. . . . The English Statute of Distribution, being founded on justice and on the wisdom of ages, was well selected as the most suitable and judicious basis on which to establish our American law of descent and distribution." See INHERITANCE. (E. R.)

INVERARAY, a royal, parliamentary, and municipal burgh of Scotland, the county town of Argyllshire, is situated at the lower end of a small bay, where the river Aray falls into the north-western waters of Loch Fyne, 40 miles north-west of Glasgow. The town is small, consisting of one street running east and west, and a row of houses facing the bay. The county buildings and court-house are handsome edifices. Near the church stands a small obelisk in memory of certain members of the clan Campbell who were executed on the spot in 1685 for preaching against Popery. The ancient market-cross, supposed to have been brought from Iona, is a fine specimen of the Scottish sculptured stones. The chief industry of Inveraray is the herring-fishery, the herring of Loch Fyne being celebrated for their excellence. To the fishing "district" of Inveraray there belonged in 1879 690 boats, 1647 fishermen and boys, and fishing-gear to the value of £31,592. In the district, or in boats fishing off its coast, 33,837 barrels of herring and 86 cwt. of cod and ling were cured in 1879. The town originally stood on the north side of the bay, clustering round the ancient baronial hold, attributed to Colin the Singular, who flourished at the end of the 14th century, but it was removed to its present site in the middle of the 18th century. Inveraray was erected into a burgh of barony in 1472; and Charles I., while a prisoner in Carisbrook Castle, raised it to a royal burgh in 1648. It is governed by a provost and council. Much has been done for Inveraray by the ducal house of Argyll, whose seat, Inveraray Castle, is a quarter of a mile to the north. This handsome square edifice, built between 1744 and 1761 and restored 1879–80, consists of two stories and a sunk floor, with round overtopping towers at the four corners. Many interesting and valuable relics were destroyed by a fire in 1877. The population of the royal burgh in 1871 was 984, and in 1881 it was 939.

INVERNESS, a maritime county of Scotland, is situated as to its mainland portion between 56° 38′ and 57° 36′ N. lat. and 3° 27′ and 5° 54′ W. long., and is bounded on the N. by Ross, N. E. by Nairn and Elgin, E. by Banff and Aberdeen, S. E. by Perthshire, S. by Argyll, and W. by the Atlantic. It measures 85 miles from north-west to south-east and 55 miles from north-east to south-west. The total area is 2,723,840 acres or 4256 square miles. The mainland portion has an area of 1,947,520 imperial acres or 3043 square miles, of which 86,400 acres or 135 square miles are under water. The area of the islands is 776,320 acres or 1213 square miles, of which the area under water is 39,040 acres or 61 square miles.

The surface of the county is very varied, consisting of ranges of lofty mountains alternating with deep narrow valleys, the beds of numerous lakes and rivers. Its exterior outline is very irregular. On the north-east a narrow tract runs out between Nairnshire and the Moray Firth. Further to the south-east a portion of it was detached till 1870, when by Act 33 & 34 Vict. c. 16 this and a similarly detached portion of Elgin were interchanged. Argyllshire penetrates it from the south-west, and Ross-shire from the north-west, while the western coast is indented by Lochs Moidart, Aylort, Nevis, Hourn, and other arms of the sea. Both the mainland and island portions abound in grand and picturesque scenery. The islands in the county are those of the Outer Hebrides (excluding Lewis, which belongs to Ross-shire, but including Harris), and Skye, Raasay, Rona, Scalpa, Eigg, etc. (see HEBRIDES). The mainland portion is divided into two nearly equal parts by the valley of Glenmore, or the Great Glen, which crosses it from the south-west to the north-east. This glen is now traversed by the Caledonian Canal, which, begun in 1803 and finally completed in 1847, at a total cost of £1,300,000, forms a line of inland navigation between the east and west seas, from the Moray Firth on the north-east to Loch Linnhe on the south-west. It has a length of 60½ miles, including about 37 miles of lakes, namely, Loch Ness with a length of 23 miles, Loch Oich of 4, and Loch Lochy of 10. On each side of this valley there are numerous glens and straths, separated by mountain ridges, and displaying, with their lakes and rivers, a great variety of beautiful scenery. The western half of the county is the more wild and mountainous. Its principal divisions are Moidart, Arisaig, Morar, Knoidart, and Glenelg, with the glens or valleys of Glengarry, Glenmoriston, Glenurquhart, and Strathglass. Among the numerous lakes in this portion of the county are Loch Shiel bordering on Argyll, Loch Arkaig, Loch Morar, Loch Quoich, and Loch Garry. The eastern half of the county comprises the extensive district of Badenoch, south-west of which lies Lochaber, and to the north the Aird. The principal valleys are Glenroy, Glen Spean, Strathspey, Stratherrick, Strathdearn, and Strathnairn; and Loch Ericht on the borders of Perthshire, Loch Treig, Loch Laggan, Loch Inch, and Loch Ouchan are among the largest lakes. The greater part of the county is occupied by mountains, many of which are over 3000 feet in height, the highest summits being Ben Nevis, 4406 feet, and Cairngorm, which is partly in Banffshire, 4095 feet. The principal rivers are the Spey, the Findhorn, and the Nairn, which flow in a north-easterly direction into the Moray Firth; the Ness, which issuing from Lock Ness flows north-eastwards, passing through the town of Inverness, and falls into the Moray Firth after a course of 6 miles; the Lochy, which flows south-westwards from Loch Lochy, and after a course of 10 miles falls into Loch Eil near Fort William; and the Beauly in the north of the county, which, after being joined by the Glass and two smaller streams, falls into the Beauly Firth. The small river Foyers, which flows northwards into Loch Ness, forms near the loch two beautiful falls, the one 30 and the other 90 feet in height.

Like the greater part of the Highlands of Scotland, Inverness-shire rests on the Old Laurentian gneiss. The Old Red conglomerate is found in Glenmore and along the sea-coast. Granite, gneiss, limestone, slate, marble, and brick-clay abound in many parts. The general direction of the rocks is from south-west to north-east. The upper part of Ben Nevis is composed of beautiful porphyry. Lead has been found on Ben Nevis and in Glengarry, but is not worked. Silver and iron ore have also been met with in small quantities. The want of coal renders the limestone of little value. On account of the irregular surface the climate of Inverness-shire is very diversified, and in many parts it is very unfavorable for the prosecution of agriculture.

According to the agricultural returns for 1880, the total area of arable land was 126,306 acres, or 4·6 per cent. (4·2 in 1870), of which 39,584, or 1·5 per cent. (1·4 in 1870), were under corn crops, 19,513, or 0·7 per cent. (0·7 also in 1870), under green crops, 27,155, or 1·0 per cent. (0·9 in 1870), under rotation grasses, 39,140, or 1·4 per cent. (1·2 in 1870), under permanent pasture, and 914 fallow. There were 160,656 acres under wood. Within the last twenty-five years great progress has been made in the reclamation of waste land, the arable land in 1855 extending only to 42,030 acres. There are nearly 300,000 acres of deer forests, and about 1,700,000 of heath land, one half of which affords pasturage for sheep, the other half being of no value except for grouse shooting. From the trees found in great numbers in the peat-bogs of the county it would appear to have been at an early period thickly covered with wood. Strathspey is still celebrated for its great forests; and the natural woods on Loch Arkaig, in Glengarry, Glenmoriston, Strathglass, Strathfarrar, and at the head of Loch Shiel are also very extensive. The forests consist chiefly of oak, fir, birch, ash, mountain ash, holly, elm, hazel, and Scotch poplar. There are also extensive plantations of larch, spruce, silver fir, beech, and plane. Part of the great Caledonian forest extends for several miles near the Perthshire boundary. The most unproductive portion of the county is that to the north-west of the Caledonian Canal, although it includes several patches of highly cultivated land. In the low districts surrounding the county town the soil and climate are both excellent, and good crops of all kinds are raised, which are not much later in reaching maturity than in the earlier districts of Scotland. The soil of the Badenoch and Laggan districts is generally good, but the climate is very uncertain, and much injury is often caused by early frosts. In many districts the grain in late seasons never reaches full maturity. In the whole of the Western Isles the soil is generally poor, and the moist climate renders it very difficult to secure the crops in good condition.

The number of holdings in June, 1880, was 6142. Of these there were 5616 of 50 acres and under, with a total extent of 47,772 acres; 248 were between 50 and 100 acres, total 17,407 acres; 237 between 100 and 300 acres; total 39,746 acres; 30 between 300 and 500 acres, total 11,408 acres; 9 between 500 and 1000 acres, total 6029 acres; and 2 above 1000 acres, total extent 4057 acres. Considerable enterprise has been shown in many districts in the improvement of land, and on the larger farms the best modern implements of husbandry are in use. The crofter system has very much decreased on the mainland, and some of the crofters now have leases of five, ten, or fourteen years, and have largely increased their cultivated holdings by reclamation. On the larger farms a nineteen years' lease is almost universal, and a five-shift course of cropping is the most common. Large numbers of admirable farm steadings have been erected within late years, and considerable progress has been made in the construction of suitable cottages for married servants. The acreage under wheat has been decreasing very much within late years: the area sown in 1878 was 352 acres, in 1879 only 82, and in 1880 146, while in 1855 it was 1539 acres. The best quality raised has always been that of the Aird and Beauly districts. Barley and bere were grown on 7855 acres in 1880 instead of 2220 in 1855. Much good barley is produced in the middle districts, such as Strathspey, Strathnairn, Strathglass, and Glenurquhart. Bere is grown mostly in the late districts and in the Western Isles. Most of the barley is manufactured into whisky in the county. Oats occupy more than three-fourths of the area under grain,—30,714 acres in 1880, instead of 13,704 in 1855. A considerable portion of this crop is of a light and inferior quality, the best being that produced on heavy clay land. There is a considerable area under rye, 814 acres in 1880 as compared with 125 in 1855. It is grown chiefly on the sandy hills south and east of Inverness. Under beans and pease there were in 1880 only 13 and 35 acres respectively. The extent under turnips and Swedes in 1880 was 11,084 acres, the proportion under Swedes being about one-sixth. Artificial manure is extensively used for the turnip crop, and on many soils the yield is very heavy. Potatoes were grown on 8252 acres in 1880. The dry soil in many parts of the county is well adapted for this crop, and on the more extensive farms they often constitute a large item in the farmer's profits.

The number of cattle in 1880 was 51,287 (24,061 in 1855), or an average of 40·5 to every hundred acres under cultivation, the average for Scotland being 23·2, and that for the United Kingdom 20·7. Of these the number of cows and heifers in milk or in calf was 22,208, and the number under two years of age 21,673. The principal breed is the Highland, the largest and best herds of which are in the Western Isles. There are a few of the polled and shorthorn breeds, and Ayrshire cows have in many places been introduced for dairy purposes. Crosses of an indefinite description are numerous in the lowlands, but in many places their quality has been improved by the use of polled or shorthorn bulls. The number of horses in 1880 was 8938 (3485 in 1855), or 7·0 to every hundred acres under cultivation, the proportion for Scotland and also for the United Kingdom being 4·1. Large numbers of Highland ponies are raised on the hill farms. The breed of agricultural horses, which in 1880 numbered 6758, has been much improved by the introduction of Clydesdale stallions. The sheep numbered 711,910 in 1880 (567,694 in 1855), or 563·7 to every hundred acres under cultivation, the proportion for Scotland being 149·3 and for the United Kingdom 63·5. The majority are either Cheviots or blackfaced, of which the numbers are about equal, Cheviots having been for some time on the increase. Leicesters and half-breeds are kept in several of the lower districts of the country. The number of pigs in 1880 was 2897 (1667 in 1855), an average of 2·3 to every hundred acres under cultivation, the average for Scotland being 2·6 and that for the United Kingdom 6·0. Not much attention is paid to the character of the breed, especially by the crofters, who rear this stock chiefly for domestic consumption.

According to the *Returns of Owners of Lands and Heritages*, 1872–73, the land was divided among 1867 proprietors; its gross annual value was £361,848, 5s, and the average value of the whole 2s. 9½d. per acre. Of the owners 83⅓ per cent. possessed less than 1 acre. There were no fewer than thirty proprietors owning more than 20,000 acres, while nineteen possessed upwards of 50,000 acres each, and an aggregate of nearly 1,900,000 acres—viz: Lord Lovat, 161,574; Earl of Seafield, 160,224; Macleod of Macleod, 141,679; Evan Baillie, 141,148; Lord Macdonald, 129,919; The Mackintosh, 124,181; Donald Cameron of Lochiel, 109,574; Sir G. Macpherson Grant, 103,372; Edward Ellice, 99,545; The Chisholm, 94,328; John Gordon of Cluny, 84,404; Sir John P. Orde, 81,099; Trustees of J. M. Grant, 74,646; Mrs. Campbell, 74,000; Colonel George G. Walker, 70,940; Sir John W. Ramsden, 60,400; Earl of Dunmore, 60,000; James Baird, 60,000; Edward H. Scott, 59,123.

Salmon yield a considerable rent on the rivers Lochy, Beauly, and Ness, and are found also in other streams and in several of the lochs. Red and roe deer, the alpine and common hare, black game and ptarmigan, grouse, partridges, and pheasants tenant the moors and woodlands. Foxes and wild cats are found, and otters are to be met with in the lakes and rivers. There are also eagles, hawks, and owls, and great numbers of waterfowl, particularly swans, resort to Loch Inch and the other lakes of Badenoch.

The manufactures of the county are unimportant. At Inverness there are two woollen manufactories, two breweries, and a distillery. The principal distilleries are Ben Nevis distillery near Fort William, Ord distillery near Beauly, Carbost distillery in Skye, and two in the neighborhood of Kingussie. There are flour mills in various parts of the county, and artificial manure is manufactured at Kirkton near Inverness.

The Highland Railway traverses the eastern corner of the county, and enters it again near Campbeltown, skirting its northern shore by Inverness and Beauly.

The only royal burgh is Inverness, the county town. The principal villages are Beauly (population 995), with some shipping trade; Campbeltown (831), frequented as a bathing-place, and possessing a chalybeate spring; Fort William (1562), near Ben Nevis, with herring and salmon fisheries; Kingussie (645); and Portree (893), in the Isle of Skye, having considerable export trade in cattle, sheep, and fish. The population of the county, which was 88,261 in 1861, and 87,531 in 1871, was found in 1881 to be 90,414 (43,785 males and 46,629 females). The maximum population was reached in 1841, when it was 97,799. In 1801 it was 72,672. The county returns one member of Parliament; and the burgh of Inverness unites with three others in returning a second.

At an early period Inverness was included in the kingdom of the Northern Picts, its mainland portion forming part of the provinces of Moravia and Arguthecla. The latter province with the islands subsequently became the possession of the Norwegians, but was afterwards known as Ergadia, and was divided into three portions, Ergadia Borealis, Ergadia quæ ad Moraviam pertinet, and Ergadia quæ ad Scotiam pertinet. For some time the capital of the Pictish kings was at Inverness in Moravia. The province was for a considerable period ruled by the mormaers of Moray, one of whom was the well-known Macbeth. The last of these mormaers was defeated by David I. Early in the 13th century the province, which up to that time had been included under one sheriffdom, was divided into the sheriffdoms of Inverness, Elgin, and Nairn.

Among the antiquarian remains of Inverness-shire are a large number of the so-called Druidical circles, especially in the northern part of the county. At Inshes, 2 miles from Inverness, there are remarkable cromlechs; and at Clava near Culloden there are large remains of old chambered sepulchres. Numerous traces exist of ancient pit dwellings similar to those of the Picts but of inferior masonry, and there are remains of crannogs or old lake dwellings at the Loch of the Clans and Loch Beauly. Two examples of the old Pictish towers still exist at Glenelg in a state of almost perfect preservation, and there are others in Glenmore and elsewhere. Among the vitrified forts the principal are those on the hill of Craig Phadraig, with ten others stretching into the interior; Dundbhairdghall on Ben Nevis; and Dun Fhion or Fingal's fort on the top of a conical hill near the river Beauly. The principal examples of other ancient fortresses are Castle Spynie, an extensive ruin on a hill about 700 feet above the plain and 2 miles east from the church of Beauly, and the remains of massive fortifications on the summit of a steep hill in the parish of Laggan. Among the old castles may be mentioned Urquhart castle, besieged and taken by the officers of Edward I. in 1303, and Inverlochy castle near Fort William. The county formerly contained three military forts. Of these Fort George, on the Moray Firth, 12 miles east of Inverness, built in 1747-67, at a cost of £160,000, is now used only as barracks; Fort Augustus, at the west end of Loch Ness, originally erected in 1730, and rebuilt after having been demolished by the rebels in 1745, is now almost obliterated, a palatial Benedictine monastery having been erected on its site; Fort William, on Loch Eil, built in the reign of William III., remains in good preservation, but is inhabited by civilians. On Culloden Moor to the eastward of Inverness was fought the battle (April 10, 1746) which closed the rebellion of 1745–46.

INVERNESS, a royal, parliamentary, and municipal burgh of Scotland, the capital of the above county, is finely situated at the northern end of Glenmore, on both sides of the river Ness, about half a mile from its mouth, and on the Highland Railway, 144 miles north-north-west of Perth, and 109 west-north-west from Aberdeen. It is built principally on the right bank of the river, which is crossed by a suspension bridge, a wooden bridge, and a railway bridge of stone. Though very ancient, the town presents quite a modern appearance, and possesses wide and handsome streets, and beautiful suburbs with numerous fine villas. Lately great improvements have taken place, several new streets having been laid out within a recent period. On an eminence to the south-west of the town stood an ancient castle in which Macbeth is said to have murdered Duncan. This was razed to the ground by Malcolm Canmore, who erected another on an eminence overhanging the town on the south. The original castle was a royal fortress, and that erected by Malcolm continued to be so till its destruction in 1746. Its site is now occupied by a castellated structure erected in 1835, and comprising the court-house, county buildings, and jail. At the northern extremity of the town Cromwell erected a fort capable of accommodating a thousand men; this was demolished at the Restoration, but a considerable part of the ramparts still remains. In the centre of the town is the town-hall, completed in 1880, in front of which is a fountain so constructed as to contain the lozenge-shaped stone called *Clach-na-Cudain*, or "Stone of the Tub," from its having served as a resting-place for women in carrying water from the river. It was regarded as the palladium of the town, and is said to have been carefully preserved after the town was burned by Donald of the Isles. The spire of the old jail, which is of fine proportions, now serves as a belfry for the town clock. In the tower there is a slight twist caused by a shock of earthquake in 1816. The other principal buildings are the episcopal cathedral of St. Andrew in the Decorated Gothic style, erected in 1866, and comprising nave, side aisles, transepts, and apsidal chancel; the academy, incorporated by royal charter in 1792, endowed originally with £20,000, to which in 1803 was added £25,000 left by Captain W. Mackintosh for the education of boys of certain families of that name; the collegiate school, the high school, the school of science and art, the new market buildings, erected in 1871 at a cost of £3100, the northern infirmary, and (outside the burgh) the new depôt for soldiers at Millburn. The cemetery is finely situated on a hill south-west of the town, and about a mile and a half west of the town is the lunatic asylum, erected in 1864. On Craig Phadraig hill, about a mile west of the town, there is a vitrified fort supposed to have been the residence of the Pictish kings. The manufacturing industries are not extensive; but there are iron-works, breweries, tanneries, woollen factories, and saw-mills. The harbor affords good accommodation for vessels, and there is considerable trade with Aberdeen, Leith, and London on the east coast, and by means of the Caledonian Canal with Liverpool, Glasgow, and Ireland. Shipbuilding is also carried on. The exports are chiefly sheep, wool, and agricultural produce, and the imports coal and provisions. In 1879 the number of vessels that entered the harbor was 2859, with a total burthen of 309,121 tons, while 2788 cleared, of 304,302 tons burthen. The population of the parliamentary burgh in the ten years 1861–71 increased from 12,509 to 14,466, and in 1881 it numbered 17,366. Inverness unites with the burghs of Forres, Fortrose, and Nairn in returning a member to Parliament.

Inverness is of great antiquity, but the exact date of its origin is unknown. At an early period it was incorporated as a town, and it was one of the Pictish capitals. In 1233 an abbey of the Dominicans was founded there by Alexander III. From William the Lion the town received four charters, one of which created it a royal burgh. In 1411 it was burned by Donald of the Isles on his way to the battle of Harlaw. The town was visited in 1427 by James I., who held a parliament within its walls, and in 1562 it was visited by Queen Mary, who, being refused admission into the castle, caused it to be taken and the governor hanged. During the civil wars the castle was repeatedly taken and occupied by the rival forces; and in 1746 it was blown up by the troops of Prince Charles Stuart. See *Invernessiana*, by Charles Fraser Mackintosh, 1875.

INVESTITURE, in feudal phraseology, means the act of giving corporal possession of a manor or office,—an act which was usually conjoined with some significant ceremonial, such as the delivery of a branch, a banner, or some other appropriate symbol of the thing conveyed. Investiture with staff and ring was during and after the 11th century the name given to the ceremony by which ecclesiastical dignitaries were admitted by the civil power to possession of the temporalities of their office. The word investiture (from "vestire," to put in possession; see Ducange) is later than the 9th century; the thing itself is an outcome of the feudal system. Under the Frankish monarchy the idea came very early into vogue that the right of nominating bishops lay with the sovereign,—an idea that gained currency all the more widely, especially in Germany, as the territorial and temporal character of the bishoprics and abbacies, with their various immunities and privileges of coinage, toll, market, and the like, gradually came into prominence, and their spiritual nature and functions were proportionally obscured. It was indeed but logical that ecclesiastics, so far as they were the holders of lands, should not be exempted from the ordinary obligations of feudatories to their suzerain; nor was this view seriously disputed until after the middle of the 11th century, when the views of Hildebrand (afterwards Pope Gregory VII.), who aimed at asserting the absolute freedom of the church from all secular control, began to prevail at Rome. Thus a Roman synod in 1063 forbade all clergymen from accepting churches at the hands of laymen; and in 1068 a direct collision took place at Milan between the German court, which had invested a bishop in the usual way, and the populace, who under papal influence insisted on the appointment of one who had been canonically elected in accordance with the views of the reforming church party. In 1075 (the second year of his pontificate) Gregory VII. in a council held at Rome (Labbé, *Conc.*, vol. xii., ed. 1730) in the most stringent terms deposed every bishop, abbot, or inferior ecclesiastic who should receive investiture from any lay person, interdicted any one who should be guilty of rebellion from all communion in the favor of St. Peter and from all fellowship with the church, and imposed a similar sentence on any emperor, duke, marquis, count, or other secular person who should presume to grant such investiture of bishopric or inferior dignity. The conflict between the empire and the Roman See, which began with this decree, was carried on with varying success throughout the whole of that pontificate, and was continued by Gregory's successors, with more than one unsuccessful effort at an adjustment, until in the concordat of Worms (1122) it was agreed between Henry V. and Calixtus II., on the one hand, that the emperor should surrender to the church the right of investiture by the ring and the pastoral staff, grant to the clergy throughout the empire the right of free election, and restore the possessions and feudal sovereignties which had been seized during the wars in his father's time and his own; while, on the other hand, it was conceded by the pope that all elections of bishops and abbots should take place in the presence of the emperor or his commissioners, and that every bishop elect in Germany should receive, by the touch of the sceptre, all the temporal rights, principalities, and possessions of the see, excepting those which were held immediately of Rome. It was also stipulated that in all other parts of the empire (Italy and Burgundy) the royalties should be granted to the freely elected bishop within six months after consecration. Later, the imperial control over the election of bishops in Germany came to be in practice much curtailed, partly by the tacitly changed relations between the empire and its feudatories, partly by explicit concessions wrung at various times from individual emperors (Otto IV. in

1209, Frederick II. in 1213); but the principles of the concordat of Worms continued theoretically to regulate the tenure of bishoprics and abbacies until the dissolution of the empire in 1806.

The question of investitures never assumed an aspect of first rate importance in France, partly because the bishoprics there partook less than in Germany of the nature of secular principalities, partly because at an early period in the dispute the sovereigns voluntarily yielded the leading claims of the church party. In England an arrangement was come to as early as 1105 between Pascal II. and Henry I., in virtue of which the king gave up the right to invest with staff and ring, but retained the right to nominate his bishops and to exact from them the oath of allegiance. A certain freedom of election, somewhat similar to that which still exists (but see BISHOP), was first conceded under Stephen, and confirmed by John in 1215.

IO is the heroine of a legend associated with the cultus of Hera, both in Argos and in Eubœa. In Argos the great temple of Hera was situated on a hill called Eubœa, on the road from Mycenæ to the city of Argos; while in Eubœa the legend was associated with the town of Argoura. The identity of names shows that the legend dates from a very ancient period of the worship; and as, in accordance with the universal rule in such legends, Io is only a form of the goddess, it is highly probable that she represents an older stage of the cultus than the better known Hera. Her transformation into a cow is clearly a relic of the primitive time when the goddess was actually worshipped under the symbol of a cow, the fertile mother, united with the male deity in the ἱερός γάμος which was annually celebrated at Argos (see HERA).

Even in the simplest form in which we know it, the legend has been much transformed by poetic fancy. As a heroine united with the country from immemorial time, Io is called daughter of Inachus, the river of Argos and its oldest king, or of Iasus, from whom comes the epithet Ἴασον Ἄργος. As associated with the oldest worship of Hera, she is called the daughter of Peiras, who made the first image of the goddess out of a pear tree at Tiryns; and Io Callithyia is, by a common device in such legends, the first priestess of the goddess. Zeus fell in love with her, and she was transformed into a white cow either by Zeus, to hide her from the rage of Hera, or by the jealous goddess herself. When Io and Hera had once been made into distinct personalities, such tales easily arose to explain the relation between them. Hera then insisted on getting this cow from Zeus, and set Argus Panoptes with his thousand eyes to watch her. Io is almost universally understood to be the moon, and Argus the star-studded nightly heaven. Argus tied the cow to the olive tree shown in the sacred grove on Mount Eubœa, or according to the poets pastured her in the fertile meadows of Lerna or Nemea. Zeus now sends his messenger Hermes, who lulls Argus to sleep with his magic wand, and slays him with the same curved sword, *harpe*, with which afterwards Perseus, the light-hero, slew the Gorgon, the power of darkness. According to another account, Argus, the darkness, is slain by a stone thrown by Hermes, *i.e.*, by the rising sun, whose sudden appearance is frequently spoken of as the throwing of a stone (Kuhn, *Entwickl. d. Mythol.*). Maddened by a gadfly, Io wanders over many lands till at last she comes to Egypt, where she regains human form and becomes the mother of Epaphus. Opinions differ much as to the interpretation of this part of the tale. It is not probable that both Zeus and Hermes figured in the original legend; and the end has certainly been adapted so as to bring Greece and Egypt into connection, and dates therefore from the time when intercourse between them became frequent and much influence was exerted by Egyptian religion on Greek thought, *i.e.*, the 7th century B. C. How far Oriental influence had affected the cultus at the period to which the origin of the legend belongs is doubtful; Preller compares the Phœnician conception of Astarte as a wandering cow. In later time Isis, who was conceived as horned (Herod. ii. 41), was connected with Io. The legend of Io was a favorite subject among Greek painters, and many representations are preserved on vases and in wall-paintings (see Overbeck, *Kunstmyth. d. Zeus*, 465).

See the works quoted under HERMES; and against the explanation of Io as the moon see Plew in *N. Jahrbb.*, 1870 and 1873.

IODINE, thus named on account of the violet color of its vapor (ἰοειδής, violet-colored), one of the so-called halogen elements, has already been partially described (see CHEMISTRY, vol. v. pp. 424–432).

Iodides occur in minute quantity in most mineral waters and in sea-water. The ashes of many marine algæ are rich in them; and formerly iodine was chiefly extracted from kelp or varec, the ashes of sea-weed, by distilling the mother liquor remaining after the separation of the less soluble salts by crystallization with manganese dioxide and sulphuric acid. Of late years, however, large quantities of iodine have been obtained from crude Chili saltpetre by a similar process.

The chief use of iodine is in the preparation of methyl-iodide, a substance employed in the manufacture of certain of the so-called aniline dyes. In medicine it is frequently applied externally as an irritant. Potassium iodide is also an important medicinal agent; and iodoform, CHI_3, a substance prepared by acting on alcohol with iodine in presence of alkali, has latterly been introduced as an agent for external application in certain diseases. Several iodides, especially ammonium, cadmium, and potassium iodide, are largely employed in photography.

Recent investigations have disclosed a number of most remarkable facts regarding the behavior of iodine, and the allied elements bromine and chlorine, which merit a brief description here. Free chlorine, bromine, and iodine are respectively represented by the formulæ Cl_2, Br_2, and I_2; that is to say, their molecules are "*diatomic*," each consisting of two atoms (comp. vol. v. pp. 405–409). On the other hand, the molecules of which sulphur vapor at a temperature of about 500° C. consists are hexatomic, as expressed by the formula S_6; but on raising the temperature these molecules undergo simplification, so that at temperatures above 800° the vapor appears to consist entirely of diatomic molecules such as are indicated by the formula S_2. It would seem that the halogens undergo a similar molecular simplification when heated.

Having devised a method of extreme simplicity for the determination of vapor density, V. Meyer was led in the summer of 1879 to determine the density of a number of elementary bodies at much higher temperatures than had previously been employed, and among others chlorine was examined. He was then led (in conjunction with C. Meyer) to the discovery that at high temperatures this gas has a very much lower density than corresponds to the formula Cl_2 (*Berichte der deutschen chemischen Gesellschaft zu Berlin*), 1879, p. 1430; comp. *ibid.*, 1880, p. 1172). Subsequently he extended his observations to bromine and iodine (*ibid.*, 1880, p. 394), and with similar results. Meier and Crafts took up the subject with the object of verifying V. Meyer's statements (*ibid.*, 1880, p. 851); they introduced several refinements in the method of operating, and determined the temperatures at which the experiments were made more accurately; in the main, however, their observations with iodine were confirmatory of V. Meyer's. V. Meyer's original results, and those of Meier and Crafts, are arranged in the following table, where the numbers in the column headed $\frac{D'}{D}$ indicate the ratio between the observed density and the theoretical density on the air scale corresponding to the formula I_2 (8·79).

V. Meyer.			*Meier and Crafts.*		
Temperature.	Density.	$\frac{D'}{D}$	Temperature.	Density.	$\frac{D'}{D}$
253°–450°	8·89, 8·83, 8·84, 8·85		445°	8·70, 8·78, 8·75	
586°	8·87, 8·71, 8·71	·99			
			677°, 682°	8·06, 8·58	·94
			757°, 770°, 765°	8·05, 8·28	·93
842°	6·68, 6·80, 6·80	·77	831°, 878°	8·04, 8·11	·92
1027°	5·75, 5·74	·65	1039°, 1059°, 1030°	7·18, 7·02, 6·83	·81
			1270°, 1280°	6·07, 5·57	·66
1570°	5·67, 5·60, 5·71, 5·81	·65	1390°	5·23, 5·31	·60

Meier and Crafts were of opinion that the highest temperature they employed was probably as high as that estimated by V. Meyer at 1570°, and the latter chemist subsequently acknowledged the justice of their criticism of his determinations of temperature, which were conducted by a calorimetric method, whereas Meier and Crafts employed an air thermometer. V. Meyer has since extended his observations to a still higher temperature, and has obtained the values 4·53, 4·55, 4·57, which are not far removed from the theoretical value 4·39, corresponding to the formula I for the iodine molecule (*op. cit.*, 1880, p. 1010).

An important series of observations by Meier and Crafts (*Comptes Rendus*, xcii. 39) on the density of iodine at various temperatures under various pressures show that at temperature below 700° and pressures below atmospheric pressure the density is constant, and corresponds to the formula I_2, and that the density diminishes more rapidly with rise of temperature.

From the earlier results obtained by Meier and Crafts, A. Naumann has calculated the rate of dissociation of iodine, on the assumption that the decomposition is expressed by the equation $I_2=I+I$, and has shown that it is in accordance with the general law of dissociation deduced from the dynamical theory of gases. He points out as especially remarkable that dissociation probably extends over 1200°, since it is only half completed at a temperature of about 1270°, and commences at least 600° lower.

The observations of Meier and Crafts indicate that the density of iodine begins to be abnormal at a temperature between 600° and 700°. The dissociation of bromine apparently does not commence at so low a temperature, and at a temperature at which the ratio of the observed to the theoretical density is ·66 for iodine, it is ·8 for bromine. Chlorine is much less readily dissociated than bromine. These results are in accordance with the general chemical behavior of the halogens. It has yet to be proved, however, that the dissociation is of the character indicated above, and that the molecules of the halogens do not undergo a less simple decomposition such as is contemplated in Sir Benjamin Brodie's calculus of chemical operations. (H. E. A.)

ION, of Chios, one of the five Greek tragic poets of the canon, was born in Chios, probably in the 74th Olympiad,—485–480 B. C. Although he seems to have lived much in his native island, where he met Sophocles in 441 B. C., he paid frequent visits to Athens, making the acquaintance of Æschylus, and becoming a warm admirer of Cimon and a severe critic of the rival statesman Pericles. His first tragedy dates from the 82d Ol., between 452 and 449 B. C.; and he is mentioned as third to Euripides and Iophon in the tragic contest of 429 B. C. In a subsequent year he gained both the tragic and dithyrambic prizes, and in honor of his victory gave a jar of Chian wine to every Athenian citizen,—a gift which would imply an ample fortune. From a passage in the *Peace* of Aristophanes (830 *seq.*), which was produced in 421 B. C., it is generally concluded that Ion died before that year. The names and a few fragments of eleven of Ion's plays remain; the latter give him a place only inferior to the three great tragic masters of Greece. He is credited by the scholiast on Aristophanes (*loc. cit.*) with having composed comedies, dithyrambs, epigrams, pæans, hymns, scholia, encomia, and elegies; and he is the reputed author of a philosophical treatise on the mystic number three. His historical or biographical works were five in number, and included an account of the antiquities of Chios.

IONA, or ICOLMKILL, a small island of the Hebrides, on the west coast of Scotland, in the county of Argyll, is situated about 8 miles south of Staffa and 1¼ miles west of the south-western promontory of Mull, from which it is separated by the shallow Sound of Iona. Its length is about 3½ and its breadth 1½ miles. The total area is about 2000 imperial acres, of which about 600 are under cultivation. Along the north-western shore patches of green pasture alternate with small irregular rocky elevations, culminating in the north of the island in Dunii, which has an elevation of about 330 feet. From the base of Dunii to the shore there is a stretch of low land consisting of shelly sand covered partly with grass, but towards the east exhibiting a surface of unbroken and dazzling whiteness. The southern part of the island consists of a combination of rocky elevations and grassy ravines, the rocks in the south-west corner presenting a bold and precipitous front to the sea. Geologically Iona is composed of Laurentian gneiss of great variety of character and very contorted stratification. Its deficiency in natural features of special interest is compensated for by the striking and various views obtained of the surrounding archipelago of islands, including the neighboring Mull and Jura, and the distant mountains of Skye. Fronting the sound is the small village of Iona or Buile Mor, consisting of about fifty cottages. There are two churches (Established and Free) and a school. Oats, barley, and potatoes are grown on the island, and it affords sustenance for about 300 cattle, 600 sheep, 20 horses, and 60 pigs; but the inhabitants are dependent for support as much on fishing as on agriculture. Population in 1861, 264; in 1871, 236; in 1881, 243.

The relics of antiquity still remaining consist of part of the cathedral church of St. Mary, the nunnery, some small chapels, a building called the bishop's house, and a number of ancient tombs or crosses. The cathedral, dating from the 13th century, is built in the usual form of a cross, and consists of nave, transept, and choir, with a sacristy on the north side and chapels on the south. A great portion of the walls and the central tower, about 75 feet in height, are still standing. It contains a number of old tombs. To the north are the remains of the conventual buildings which from a Norman arcade still standing appear to have been of an older date than the cathedral. The chapel of St. Oran or Odhrain situated in the cemetery, on the south side of the monastery, dates probably from the 11th century, and its western doorway presents a Norman arch with the beak-head ornament. The cemetery, called in Gaelic *Reilig Oiran*, the burial-place of kings, and said to contain the remains of forty-eight Scottish, four Irish, and eight Danish or Norwegian monarchs, possesses a large number of monumental stones. The remains of the nunnery exhibit traces of Norman architecture. Of the numerous crosses erected in the island the finest are Maclean's cross and St. Martin's cross, which are still almost entire. Both are richly carved with Runic knots and various emblematic devices and fanciful scrolls.

The original form of the name Iona was Hy, Hii, or I, the Irish for island. By Adamnan in his *Life of St. Columba* it is called *Ioua insula*, and the present name Iona originated in some transcriber mistaking the *u* in *Ioua* for an *n*. It also received the name of Hu-colum-kill (Icolmkill), that is, the island of Columba of the Cell, while by the Highlanders it has been known as Innis nan Druidhneah, the island of the Druids. It was in the year 563 that Columba, after leaving the shores of Ireland, entered the creek of Iona now known as *Port-a-churraich*, the port of the coracle, and, having satisfied himself of the suitability of the island for his purpose, founded there his famous monastery. The island was then inhabited by a Pictish population, but it has been disputed whether Columba obtained the grant of it from Conall, king of Dalriada, or from Brude, king of the Picts. Columba was buried in Iona, but between 802 and 807 his remains were transferred from it to the church of St. Patrick in the county Down, Ireland. For a long time the monastery of Iona held the supremacy among all the monasteries and churches founded by Columba and his disciples. It was several times plundered and burned by the Norsemen, and its inmates on more than one occasion put to death. The Western Isles having come into the possession of Scotland in 1072, the monastery of Iona was rebuilt and endowed by Queen Margaret. In 1092 they were, however, ceded to Magnus Barefoot of Norway, who after the renewal of the cession by Edgar in 1097 visited Iona and allowed the people to retain their possessions. The diocese of the isles, founded about 838, of which Iona was the seat, was united by Magnus to the bishopric of Man, and made subject to the archbishopric of Drontheim in Norway. A new monastery as well as a nunnery was founded by the Benedictines in 1203, and the Benedictine order either absorbed or expelled the Celtic community. About 1507 the island again became the seat of the bishopric of the Isles. The monastery was demolished in accordance with the Act passed by the Convention of Estates in 1561. For many centuries it was much frequented on account of its facilities for learning, and, as may be supposed, became after the death of Columba a great resort of pilgrims, many of whom came in order to die on the island that their remains might be interred in its sacred soil; while the remains of persons illustrious in rank or in piety were brought to it for burial from all parts of northern Europe. The site of the old monastery was about a quarter of a mile north from the present ruins.

See, in addition to the article COLUMBA, and the old authorities therein cited, Montalembert's *Monks of the West*, vol. iii.; *The Cathedral or Abbey Church of Iona*, by Bishop Ewing, 1866; *Iona*, by the Duke of Argyll, 1870; Skene's *Celtic Scotland*, vol. ii., 1877; and *Sculptured Monuments in Iona and the West Highlands*, by James Drummond, 1881.

IONIA, in ancient geography, was the name given to a portion of the west coast of Asia Minor, adjoining the Ægean Sea, and bounded by Lydia towards the east. Like the adjoining districts of Æolis on the north and Doris on the south, it was not a country or region marked out by any natural boundaries, but merely consisted of a strip of land near the coast, of comparatively small breadth, which, together with the adjacent islands, was occupied by Greeks of the Ionic race, and was thus permanently distinguished from the interior district, which was inhabited by the Lydians.

According to the tradition universally received among the Greeks, the cities of Ionia were founded by emigrants from Greece on the other side of the Ægean, and their settlement was connected with the legendary history of the Ionic race in Attica and other parts of European Greece, by the statement that the colonists were led by Neleus and Androclus, the two sons of Codrus, the last king of Athens. In accordance with this view a definite date was assigned to the Ionic migration, as it was called by later chronologers, who placed it one hundred and forty years after the Trojan war, or sixty years after the return of the Heraclidæ into the Peloponnese. It is hardly necessary to remark that no reliance can be placed upon this chronological statement; and it is altogether improbable that the colonization of the whole of this important district took place at the same period. All analogy would lead us to suppose that the foundation of the different cities which ultimately constituted the Ionic League took place at different times, and was perhaps spread over a long period of time. It is, however, not improbable that the great Dorian invasion of the Peloponnese, which gave rise to such extensive changes in the population of European Greece, may have given the first impulse to the migration of a large part of the Ionian inhabitants to the opposite shores of the Ægean. Nor is there anything unlikely in the fact that a body so composed should have put themselves under the command of a leader or œkist from Athens, which was generally looked upon as the special representative of the Ionian race.[1] But Herodotus himself tells us (i. 146) that they were very far from being of unmixed Ionic descent, and comprised settlers from many different tribes and cities of Greece (a fact indicated also by the local traditions of the different cities), as well as by intermarriage with the native races whom they found in possession of the country. A striking proof of this was to be found in the fact that so late as the time of the historian several distinct dialects were spoken by the inhabitants of different cities within the limits of so restricted an area.

Some modern critics have supposed that the population of this part of Asia was originally of Ionic race, and that the settlers from Greece found the country in the possession of a kindred people. But no trace is found in any ancient writers of such a fact, or of the distinction established by these modern scholars between the so-called Old Ionians and New Ionians. All that we know upon anything like historical evidence is that at the earliest period when we hear of any Greek population as existing on the east coasts of the Ægean we find there a large group of cities, distinct in dialect and institutions from those to the north and south of them, and generally regarded both by themselves and their neighbors as derived by direct immigration from the people who bore the name of Ionians in European Greece. Of the period of their settlement in Asia we have no trustworthy evidence; but it appears to have been anterior to the rise of the Lydian monarchy, which gradually became their most formidable neighbor.

The cities comprised under this name in historical times were twelve in number,—an arrangement copied as it was supposed from the constitution of the Ionian cities in Greece, which had originally occupied the territory in the north of the Peloponnese subsequently held by the Achaians. These were (proceeding from south to north)—Miletus, Myus, Priene, Ephesus, Colophon, Lebedus, Teos, Erythræ, Clazomenæ, and Phocæa, together with the two important islands of Samos and Chios. Smyrna, which subsequently assumed so prominent a position among the cities of this part of Asia, was originally an Æolic colony, but was afterwards occupied by a band of Ionians from Colophon, and became thenceforth an Ionian city,—an event which had taken place before the time of Herodotus. But at what period it was admitted as a member of the Ionian League we have no information.

The cities above enumerated unquestionably formed a kind of league or confederacy among themselves, of which their participation in the Pan-Ionic festival was the distinguishing characteristic. But, like the Amphictyonic League in Greece itself, this was rather of a sacred than a political character; every city, as usual among the Greeks, enjoyed absolute autonomy, and, though common interests often united them for a common political object, they never formed a real confederacy like that of the Achaians or Bœotians; and the advice of Thales of Miletus to combine in a more intimate political union found no approval among them.

The territory thus occupied was of small extent, not exceeding 90 geographical miles in direct length from north to south, with a breadth varying from 20 to 30 miles, but to this must be added the remarkable peninsular promontory of Mimas, together with the two large islands. So intricate indeed is the coast-line that the *periplus* or voyage along its shores was estimated at 340 geographical miles, or nearly four times the direct distance. A great part of this area was, moreover, occupied by mountains, none of them attaining to any great elevation, but filling up a considerable space. Of these the most lofty and striking were—Mounts Mimas and Corycus, in the peninsula which stands out to the west, facing the island of Chios; Mount Sipylos, to the north of Smyrna; Mount Corax, extending to the south-west from the Gulf of Smyrna, and descending to the sea between Lebedus and Teos; and the strongly marked range of Mount Mycale, which is in fact a kind of continuation of the chain known as Mount Messogis in the interior, and forms the bold headland of Trogilium or Mycale, opposite to the island of Samos. None of these mountains attain a height of more than from 3000 to 4000 feet; but they for the most part form abrupt and detached ranges, intersecting the country in different directions. Confined as it thus was, the narrow district in question had the advantage of comprising three broad valleys, formed by the outflow of three rivers, among the most considerable in Asia Minor: the Hermus in the north, flowing into the Gulf of Smyrna, though at a considerable distance from the city of that name; the Cayster, which flowed under the walls of Ephesus; and the Mæander, which in ancient times discharged its waters into the deep gulf that bathed the walls of Miletus, which has been gradually filled up by its continued action. These valleys were all of them extremely fertile, and besides them many smaller tracts were to be found between the mountains and the sea, of great fertility, and enjoying the advantage of a peculiarly fine climate, for which this part of Asia Minor has been famous in all ages. The consequence is that Ionia enjoyed the reputation in ancient times of being the most fertile of all the rich provinces of Asia Minor; and even in modern times, though very imperfectly cultivated, it produces abundance of fruit of all kinds, and the raisins and figs of Smyrna supply almost all the markets of Europe.

---

[1] Concerning the Ionian race in Greece, the reader is referred to the article GREECE, vol. xi., p. 73.

The colonies founded in such a favored land speedily rose to opulence and prosperity. Miletus especially was at an early period one of the most important commercial cities of Greece, and in its turn became the parent of numerous other colonies, which extended all around the shores of the Euxine and the Propontis, from Abydus and Cyzicus to Trapezus and Panticapæum. Phocæa also was one of the first Greek cities whose mariners explored the distant shores of the western Mediterranean, where they founded on the coast of Gaul the important colony of Massilia. Ephesus also, though it did not send out any colonies of importance, from an early period became a flourishing and opulent city, and gradually attained to a position in this part of Asia corresponding in some measure to that of Smyrna at the present day.

The first event in the history of these Ionian cities of which we have any trustworthy account is the invasion, or rather inroad, of the Cimmerians, a nomad people from beyond the Euxine, who ravaged a great part Asia Minor, including the neighboring Lydia, and even sacked Magnesia on the Mæander, but were foiled in their attack upon Ephesus. This event may be referred to the middle of the 7th century B. C. A more formidable danger soon threatened the Ionian Greeks from the rising power of the Lydian monarchy. Gyges, the first king of the Mermnad dynasty (about 700 B. C.), already invaded the territories of Smyrna and Miletus, and is even said to have taken Colophon, as his son Ardys did Priene. But neither conquest was durable, and it was not till the reign of Crœsus (560–545 B. C.) that the cities of Ionia successively fell under the dominion of the Lydian monarch. The defeat of Crœsus by Cyrus was followed by the conquest of all the Ionian cities by the Persian general Harpagus, and they henceforth became subject to the Persian monarchy, in common with all the other Greek cities of Asia. In this position they enjoyed a considerable amount of autonomy, but were for the most part subject to the rule of local despots. It was at the instigation of one of these, Histiæus of Miletus, that in about 500 B. C. the principal cities broke out into insurrection against Persia, in which they were at first assisted by the Athenians, with whose aid they even penetrated into the interior, and burnt the important city of Sardis, an event which ultimately led to the Persian invasion of Greece. But this first success was of little avail; the fleet of the Ionians was defeated in a great battle off the little island of Lade, and the capture and destruction of Miletus, after a long protracted siege, was followed by the reconquest of all the Asiatic Greeks, insular as well as continental (494 B. C.).

The victories of the Greeks during the great Persian war had the effect of enfranchising their kinsmen on the other side of the Ægean; and the battle of Mycale (479 B. C.), in which the defeat of the Persians was in great measure owing to the revolt of the Ionians, secured their emancipation from the Persian yoke. They henceforth became, like most of the inhabitants of the islands, the dependent allies of Athens, though still retaining their autonomy, which they preserved until the peace of Antalcidas in 388 B. C. once more placed them, as well as the other Greek cities in Asia, under the nominal dominion of Persia. They appear, however, to have retained a considerable amount of freedom until the invasion of Asia Minor by Alexander the Great brought about a fresh change. After the battle of the Granicus most of the Ionian cities submitted at once to the conqueror; Miletus alone held out, and was not reduced till after a long siege, 334 B. C. From this time they passed successively under the dominion of the Macedonian rulers of Asia, but continued to enjoy a state of great prosperity, both under these Greek dynasties and after they had been united as a part of the province of Asia with the all-absorbing empire of Rome.

There was indeed one striking exception to this prosperity. Miletus, so long one of the chief cities of Ionia, gradually sank into complete decay, a circumstance owing not so much to political as to physical causes, the mass of alluvial matter brought down by the river Mæander having gradually filled up the Latmian Gulf, on which it was situated, so that the island of Lade was ultimately joined to the mainland, and Miletus itself altogether ceased to be a seaport. The same cause has at a later period produced the same effect, though in a less degree, with the city of Ephesus; while the continually advancing deposits of the Hermus threaten, at no distant period, unless prevented by the skill of modern engineers, to close up the still more extensive Gulf of Smyrna.

It has been mentioned that the Ionian cities were accustomed to celebrate in common a festival called the Pan-Ionia; the sanctuary at which this was celebrated, and which was also called the Pan-Ionium, was situated on the northern slope of Mount Mycale, in the territory of Priene. But, besides this common religious centre, Ionia contained also two of the most celebrated shrines in all Asia, the temple of Artemis at Ephesus, and that of Apollo at Branchidæ near Miletus. It is probable that both sites were connected with local centres of more ancient religious worship, and were adopted by the Ionian Greeks when they first settled in Asia. (E. H. B.)

IONIAN ISLANDS, the ordinary collective name of Corfu (*Κέρκυρα*), Cephalonia (*Κεφαλληνία*), Zante (*Ζάκυνθος*), Santa Maura (*Λευκάς*), Ithaca, Cerigo (*Κύθηρα*), and Paxo, with their minor dependencies. As the islands are seven in number they are often called the Heptanesus (*Ἑπτάνησος*) in Greek, and Heptanesian or Septinsular is the corresponding adjective. The history of the use of Ionian as the distinctive epithet of the islands is sufficiently obscure; but it is probable that, like the application of the name Ionian Sea to this part of the Mediterranean, it is due to the settling of Ionian colonists on the coasts and islands. The islands have no real geographical unity beyond that involved in the fact that, with the exception of Cerigo, situated off the south coast, they are all within a little distance of the west coast of Greece or Albania. Corfu is separated from the mainland by not more than 2 miles, while the passage from it to Santa Maura, the nearest of the larger islands, is no less than 46. Since 1863 the whole Heptanesian territory has been incorporated with the kingdom of Greece, and the several islands have been assigned to different administrative divisions. Corfu, Cephalonia, and Zante each gives its name to one of the thirteen nomarchies of the kingdom; Cerigo is part of the nomarchy of Argolis and Corinth. The area of the seven islands is computed at 1041 square miles. The population shows a steady increase: in 1836 it was 204,242 (110,496 males, 93,746 females); in 1854, 228,981 (123,254 males, 105,727 females); in 1870, 229,516; and in 1879, 244,433.

Corfu has a denser population than any other part of Greece, more than 350 inhabitants to the square mile; and Zante ranks next with about 300. The city of Corfu, with its 25,000 inhabitants, is the third in size of the Greek towns, being exceeded only by Patras (Patrai) and Athens.

The following table shows the details of the last census:—

Nomarchy.		Males.	Females.	Total, 1879.	Total, 1870.
Corfu (Kerkyra).	Corfu	13,402	13,292	26,694	25,729
	Messe	12,697	11,631	24,328	21,754
	Oros	14,191	12,811	27,002	24,983
	Leucas	12,185	10,898	23,083	20,892
	Paxo	2,651	2,351	5,002	3,582
		55,126	50,983	106,109	96,940
Cephalonia	Craneia	15,698	16,505	32,203	33,358
	Palle.	9,651	9,352	19,003	17,377
	Same	7,925	9,190	17,115	16,774
	Ithaca	6,305	5,917	12,222	9,873
		39,579	40,964	80,543	77,382
Zante (Zakynthos). Part of Argolis and Corinth.	Zante	23,935	20,587	44,522	44,557
	Cerigo (Kythera)	6,750	6,509	13,259	10,637
	Total	125,390	119,043	244,433	229,516

As the Ionian Islands have no geographical unity, their political unity is of comparatively modern date. A Septinsular or Heptanesian history, as distinguished from the individual histories of the seven islands, is consequently in its earlier chapters a mere conventional composition produced by gathering together a variety of scarcely connected facts. To a certain extent indeed the various islands have passed under the same succession of influences: they have been subjected to the same invasions, and have received accessions to their populations from the same currents of migration or conquest; but in the degree in which even what may be considered as common experiences have affected the individual islands there has been no small diversity. In the matter of population, for instance, the island of Corfu has undergone much more important modifications than the island of Ithaca. For such facts as the establishment of Ulysses in Ithaca, the settlement of a Corinthian colony in Corfu, and the origin of the Peloponnesian War in a dispute between the colony and the "metropolis," the reader will consult the separate articles Corfu, Ithaca, etc.

The beginning of Heptanesian history may be said to date from the 15th century. Though it is true that Leo the Philosopher (about 890 A. D.) formed all or most of the islands into a distinct province under the title of the Tema of Cephallenia, and that in this condition they belonged to the Eastern empire after Italy had been divided into various states, this political or administrative unity could not last long in the case of islands situated, as they were, in the very meeting place of opposite currents of conquest. Robert Guiscard, having captured Corfu (1081) and Cephalonia, might have become the founder of a Norman dynasty in the islands but for his early death at Cassopo. Amid the struggles between Greek emperors and Western crusaders that continued to fill the 12th century, Corfu, Cephalonia, Zante, etc., emerge from time to time; but it was not till the Latin empire was established at Constantinople that the Venetians, who were destined to give the Ionian Islands their place in history, obtained possession of Corfu. They were afterwards robbed of the island by Leon Vetrano, a famous Genoese corsair; but he was soon defeated and put to death, and the senate, to secure their position, granted fiefs in Corfu to ten noble families in order that they might colonize it (1206). The conquest of Cephalonia and Zante followed, and we find five counts of the family of Tocco holding certainly the former island, and probably the latter as well as Santa Maura, as tributary to the republic. But the footing thus gained by the Venetians was afterwards lost, and through the closing part of the 13th and most of the 14th century the islands were a prey by turns to corsairs and to Greek and Neapolitan claimants. In 1386, however, the people of Corfu made voluntary submission to the republic which had now risen to be the first maritime power in the Mediterranean, and in 1401 (August 16th) the senate, with mercantile caution, secured their possession of the island from any claim which might be asserted by the kings of Naples through the duchy of Taranto by obtaining a ratification of their title from Ladislaus for the sum of 30,000 ducats. In 1485 Zante was purchased from the Turks in a very depopulated condition; and in 1499 Cephalonia was captured from the same masters; but Santa Maura, though frequently occupied for a time, was not finally attached to Venice till 1684, and Cerigo was taken only in 1717.

On the fall of the Venetian republic in 1797, the treaty of Campo Formio, which gave Venice to Austria, annexed the Ionian Islands to France; and in 1798 the French Government ratified the arrangement, and their division into three departments. But a Russo-Turkish force came to drive out the French at the close of that year; and in the spring of 1799 Corfu capitulated. By treaty with the Porte in 1800, the emperor Paul erected the Republic of the Seven United Islands, which, with various modifications, was but another name for anarchy and confusion, till a secret article in the treaty of Tilsit, in 1807, declared the Ionian Islands an integral part of the French empire. They were incorporated with the province of Illyria, and in this condition they remained till the decline of the French power. The British forces, under General Oswald, took Zante, Cephalonia, and Cerigo in 1809, and Santa Maura in 1810; Colonel Church reduced Paxo in 1814; and after the abdication of Napoleon, Corfu, which had been well defended by General Donzelot, was, by order of Louis XVIII., ceded to Sir James Campbell. By the treaty of Paris (9th November, 1815) the contracting powers—Great Britain, Russia, Austria, and Prussia—agreed to place the "United States of the Ionian Islands" under the exclusive protection of Great Britain, and to give Austria the right of equal commercial advantage with the protecting country, a plan strongly approved by Count Capodistrias, the famous Corfiot noble who afterwards became president of the new republic of Greece.

The terms of the treaty were unfortunately not only of indefinite import, but, if not actually self-contradictory, at least susceptible of contradictory interpretation. And, still more unfortunately, instead of interpreting the other articles in harmony with the first, which declared the islands one "sole free and independent state," the protecting power availed itself of all that they contained in support of the extension of its authority. The first lord high commissioner, Sir Thomas Maitland, who as governor of Malta had acquired the sobriquet of "King Tom," was not the man to foster the constitutional liberty of an infant state. The treaty required, with questionable wisdom, that a constitution should be established, and this was accordingly done; but its practical value may be judged of from the fact that the budget presented to the assembly of representatives in 1840, without risk of discovery, consisted of so much blank paper,—duly bound, it is true, in purple velvet. The constitution, which came into force in January, 1818, placed the administration in the hands of a senate of six members and a legislative assembly of forty members; but the real authority was vested in the commissioner, who was able directly to prevent anything, and indirectly to effect almost anything. Sir Thomas Maitland was not slow to exercise the control thus permitted him, though on the whole he did so for the benefit of the islands. The construction of roads, the abolition of direct taxes and of the system of farming the church lands, the securing of impartial administration of justice, and the establishment of educational institutions are among the services ascribed to his efforts. These, however, made less impression on the Heptanesians than his despotic character and the measures which he took to prevent them giving assistance in the Greek war of Independence in 1821. He was succeeded in 1823 by General Sir Frederick Adams, who in the main carried out the same policy, though he showed more favor to the aristocracy. It was under his government that the new fortifications of Corfu began to be constructed, and that some of the most important public works which still do honor to the English protectorate were undertaken. In Cephalonia the credit belongs, however, to Colonel Napier, one of the most able and arbitrary Englishmen who had to do with the islands. Lord Nugent, who became commissioner in 1832, began by allowing the parliament greater freedom, but was afterwards compelled to revert to the previous method of management. Sir Howard Douglas, his successor (1835–1841), had a stormy reign. He ruled with a firm, too often with a high hand; and he was met by continual intrigues, contentions, and calumnies. The parliament was prorogued in 1831, 1841, and 1842, the principal exponent of the opposition being the famous Mustoxidi (who died in 1861). A complete change of policy was inaugurated by Mr. Mackenzie (1841–43), but his relations to the home Government, rendered more embarrassing by a bold act of his own, led to his speedy resignation. Lord Seaton (1843–49) was induced by the European disturbances of 1848 to propose and urge on a number of important reforms in the constitution; and in 1848 liberty of the press was granted by statute. Freedom of election, both parliamentary and municipal, a large extension of the franchise, and the restoration of voting by ballot were among the concessions of 1849. The assembly (the ninth) first elected under the extended franchise had

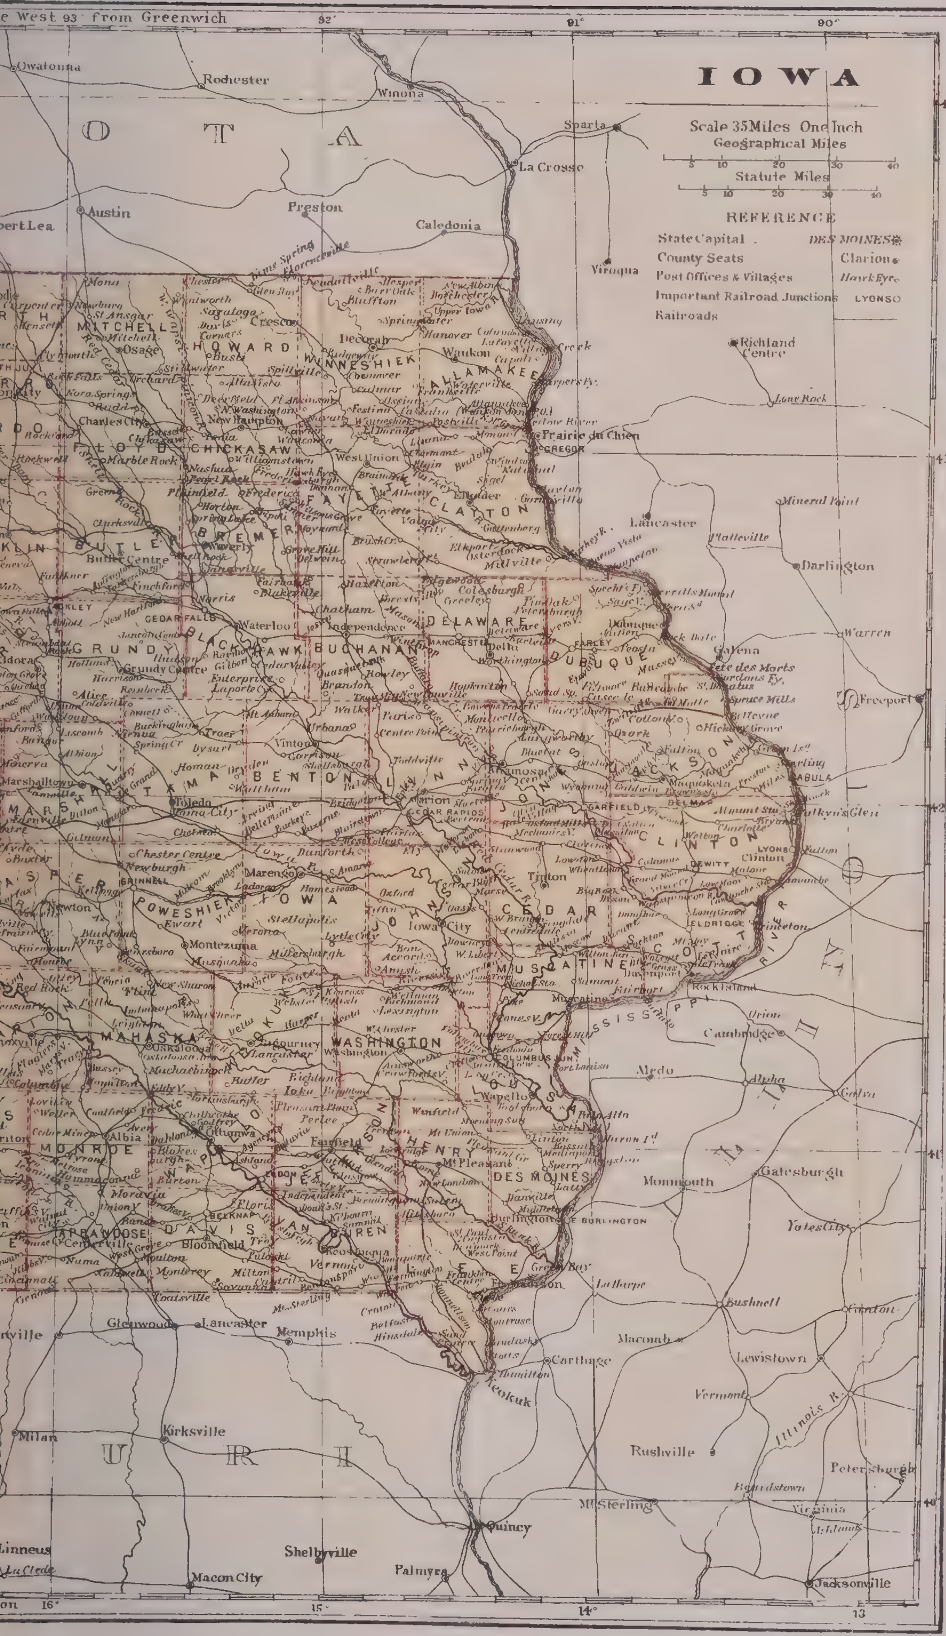
PLATE II.



ICA, NINTH EDITION.

J. M. Stoddart & Co. Publishers

to be twice prorogued by Sir Henry Ward (1849–1855), and was finally dissolved in 1861; and the growing hostility to the Government was vainly met by banishment of members of assembly and editors of papers. The party which wished for union with Greece was rapidly growing in vigor and voice. Serious insurrections of the peasantry, especially in Cephalonia, had to be put down by military force both by Lord Seaton and Sir Henry Ward. Sir John Young (1855–1859) found the tenth parliament of the same temper as the ninth: in its first session it passed a resolution in favor of immediate union with Greece. The hostility of the unionist party to the commissioner himself was increased by the publication (1858) of one of his despatches (stolen from the colonial office), in which he recommended that "Corfu and Paxo should, with the consent of their inhabitants, be converted into English colonies, and that only the southern islands should be handed over to Greece." About the same time, however, the hopes of the unionists were roused by the appointment of Mr. Gladstone as high commissioner extraordinary to investigate into the condition of the islands. From his eminence in Greek scholarship, and his known sympathy with Greek independence, it was their expectation that he would support if he did not satisfy their pretensions. But after a tour through the principal islands Mr. Gladstone came to the conclusion that the abolition of the protectorate was not the wish of the mass of the people, and the cordial reception which he owed to his own reputation and character was too much ascribed by him to the general goodwill of the Ionians to the English Government. For a few days in 1859 he held office as lord high commissioner, and in that capacity he proposed for the consideration of the assembly a series of reforms. These reforms were, however, declared inadmissible by the assembly; and Sir Henry Storks (February 16, 1859), who succeeded to the difficult post which Mr. Gladstone resigned, began his rule by a prorogation. The contest continued in the same style between the assembly and the protectorate. The English Government was slow to realize the true position of affairs: as late as May, 1861, Mr. Gladstone spoke of the cession of the islands as "a crime against the safety of Europe," and Sir Henry Storks continued to report of tranquillity and contentment. The assembly of 1862 accused the commissioner of violation of the constitution and of the treaty of Paris, and complained that England remained in ignorance of what took place in the islands. During this time there had been considerable agitation in Greece owing to the disfavor in which King Otto (of Bavaria) was held. On the abdication of that prince in 1862 the Greek people by universal suffrage voted Prince Alfred of England to the throne, and when he declined to accept the crown England was asked to name a successor. The prince proposed was William, brother of the Princess of Wales; and the English Government declared to the provisional Government of Greece that if they accepted him (which they did) his power would be strengthened by the long-refused cession of the Ionian Islands. In 1863 the commissioner laid before the parliament (the thirteenth) the conditions on which the cession would be carried out. The rejection of one of these conditions—the demolition of the fortifications of Corfu—led to a new prorogation; but none the less (on November 14, 1863) the plenipotentiaries of the five great powers signed the protocol by which the protectorate was brought to a close. The neutrality which they attributed to the whole of the islands was afterwards (January, 1864) confined to Corfu and Paxo. On May 30 of that year the lord high commissioner handed over the archives of the state to General Zaimis, the Greek plenipotentiary; and on the following day he left Corfu with the English troops and men-of-war. King George (Prince William of Schleswig-Holstein) made his entry into the capital on June 6th. The eighty representatives of the Ionian Islands took their places in the national parliament in July.

I.*, London, 1863; Viscount Kirkwall, *Four Years in the I. I.*, London, 1864, vol. i. containing a chronological history of the British protectorate; F. Lenormant, *La Grèce et les îles Ioniennes*, Paris, 1865; P. Hiotis (Χιωτις), *Hist. des îles Ioniennes*, Zante, 1815–64. Mardo's *Saggio di una descrizione geografico-storica delle Isole*, Corfu, 1865, is mainly geographical. De Bosset's *Description des monnaies d'Ithaque et de Cephalonie*, London, 1815, is an early contribution to the subject, fully treated by Postolakas, Κατάλογος τῶν ἀρχαίων νομισμάτων τῶν νήσων Κέρκυρας, Λευκάδος, etc., Athens, 1868. For the linguistic peculiarities of the islands reference may be made to Tsitselis, Γλωσσάριον Κεφαλληνίας, Athens, 1876.

Plate II.

IOWA, one of the north-western States of the American Union. Its boundary lines are—on the S. and N. the parallels 40° 36′ and 43° 30′ of N. lat., on the E. the Mississippi river, and on the W. the Missouri and Big Sioux rivers. The south-eastern corner projects slightly below the parallel of 40° 36′, the boundary following the Des Moines river down to its mouth. The neighboring States are —Minnesota on the north, Wisconsin and Illinois on the east, Missouri on the south, and Nebraska and Dakota on the west. The length of the State from north to south is about 200 miles, and its greatest breadth from east to west 300 miles. Its area is 35,228,800 acres, or 55,045 square miles.

The State lies entirely within the prairie region of the Mississippi valley, and has a level or undulating surface. Its mean height above the sea is 925 feet,—ranging from 500 in the south-east to 1700 in the north-west. About 24,600 square miles of the area rise less than 1000 feet above sea-level.

The surface presents very little relief. A broad elevation (1700 feet at the north boundary, and decreasing gradually southwards) separates the waters of the Mississippi from those of the Missouri. The position of this "divide" is, for the most part, near the western border of the State, giving to the branches of the Mississippi long courses and an easy fall, while those of the Missouri have comparatively short courses and a rapid fall. Near their sources, these branches, both of the Mississippi and Missouri, flow in broad, shallow valleys. Farther down their courses, however, bluffs develop, and increase gradually in height, while the valleys in general become narrower. The bluffs bordering the valley of the Mississippi range in height from 200 to 400 feet, the valley between them being usually from 4 to 8 miles in width, although in a few places, as at Dubuque, they close in upon the river on both sides. On the Missouri the bluffs range from 200 to 300 feet in height, enclosing a bottom land 5 to 12 miles in width.

Rivers and Lakes.—The Mississippi and Missouri are the only navigable rivers. They have ample depth of water for all purposes of inland navigation. At two points upon the former river, indeed (at Rock Island and near Keokuk), there are rapids which at low water form partial obstructions to navigation; but at high water steamers can run them in either direction. A canal is now being made to facilitate the passage of the lower or Des Moines rapids, and works are projected for the improvement of the upper or Rock Island rapids. The other rivers are the Upper Iowa, Turkey, Maquoqueta, Wapsipinicon, Iowa, Cedar, Skunk, or Checauqua, and Des Moines, flowing into the Mississippi, and the Chariton, Nodaway, Grand, Nishnabotany, and Little and Big Sioux, flowing into the Missouri. None of these streams are navigable. A few small lakes are found in the north-west, on or near the divide between the two great rivers. The area of swamp and marsh surface is proportionally small, and is rapidly diminishing.

Forests.—As in most of the prairie region of the Mississippi valley, there is in this State but little forest, the timber being confined to the bottom lands of the streams and the faces of the bluffs. The commonest trees are the oak, elm, cottonwood, black walnut, hickory, maple, and linden. Upon the bluffs is found a sparse growth of pines and red cedar.

Geology.—The geology of the State is remarkably simple; excepting in the north-western quarter, where the formations are so covered with Quaternary drift as to be unrecognizable, there is from north-east to south-west a succession of belts, from the Lower Silurian to the top of the Carboniferous, varying in breadth and extending north-west and south-east. The Silurian occupies but a comparatively small area in the north-eastern corner. A strip of Devonian follows, 40 to 50 miles in width, extending from Davenport on the Mississippi north-westward to the northern boundary. The south-western half of the State is overlaid by the different members of the Carboniferous formation, with here and there fragments of Cretaceous beds, which have survived the enormous erosion to which the surface has everywhere been subjected.

Minerals.—It is estimated that about 7000 square miles are underlaid by the Coal-measures. Within this area coal beds of workable thickness and quality have been found at Fort Dodge, Moingona, Des Moines, and Oskaloosa, where they are being extensively worked. The coal is bituminous, no anthracite having been found in the State. The north-eastern part of Iowa is included within the great lead region of the Upper Mississippi; and, although the palmy days of the mines of that region are over, the product is yet very important. The ore, which is galena, is found in pockety deposits in the limestones of the Silurian formation. These deposits vary immensely in size, and in general extend to no great depth, and therefore cannot be relied upon for permanence.

Climate.—The climate resembles in its essential features that of the rest of the prairie States, excepting that towards the west the aridity of the atmosphere and the decreased rainfall characteristic of the great plains begin to be perceptible. The annual rainfall ranges from 24 to 44 inches, with an average of about 36 inches, the south-eastern portion receiving the greatest amount, and the western part the least. The mean annual temperature ranges from 42° to 52° Fahr., the summer mean from 66° to 79° and the winter mean from 14° to 27° showing a difference between the summer and winter temperatures of 52°. The highest single observed temperatures have been 95° to 105°, and the lowest 18° to 33° below zero, an extreme range of about 125°. The south-eastern portion has the mildest and most equable temperature, as well as the greatest rainfall. Northward and westward the temperature becomes lower and extremes greater.

Soil.—The soil is extremely fertile, whether drift, bluff, or alluvial. The drift, whose name explains its origin, covers the greater part of the State. It is a dark loam, 1 to 2 feet in depth, and of almost inexhaustible fertility. The bluff soil or loess occupies the country bordering upon the valley of the Missouri. It is supposed to be a subaerial deposit, brought by the prevalent westerly winds from the plains of Nebraska and Dakota, and deposited here near the borders of the humid region. It has a great depth, reaching 200 feet in some instances, and is everywhere extremely rich. The alluvial soil, found in the valleys and bottom lands, is the deposit of the streams, and varies in composition with the country which the streams have traversed above. Much of it on the Missouri and its branches is composed of loess, while that on the Mississippi is mainly altered drift deposits.

Agriculture.—The agricultural interest is by far the largest and most important of the State. In the production of Indian corn it ranks second, and of wheat fifth, among the States of the Union. The following table, taken from the report of the department of agriculture, shows the amount of the agricultural products for 1879:—

	Number of acres under each Crop.	Product.	Value.	Average yield per acre
		Bushels.	$	Bushels.
Indian Corn..	4,873,400	185,189,200	44,445,408	38·0
Wheat	3,214,400	32,786,880	30,163,930	10·2
Rye	23,400	365,040	197,122	15·6
Oats	1,034,900	37,256,400	8,568,972	36
Barley	195,000	4,290,000	1,930,500	22
Buckwheat ...	8,000	144,000	99,360	18
Potatoes........	105,700	9,090,200	2,908,864	86
		Tons.		Tons.
Hay.....	2,314,286	3,564,000	16,180,560	1·54

The numbers of different classes of live stock were—horses, 778,400; mules, 44,700; milch cows, 724,500; other cattle, 1,370,400; sheep, 454,400; hogs, 2,778,400. In number of horses Iowa ranks as the fifth, of milch cows and other cattle third, and of hogs second, among the States. The average value of cleared farming land in the State in 1879 was $27·30 per acre; of timber land, $39·36. The increased value of the latter is due to the scarcity of forests. The average monthly wages paid to agricultural laborers during the same year was $23·26; average daily wages, on transient employment, $2·01.

Manufactures.—The manufacturing industries have not yet reached a high degree of development. Those branches connected with agriculture have naturally made most advance. The following statistics, from the results of the tenth census (1880), show the condition of these industries.

Industries, 1880.	Number of Establishments.	Capital.	Greatest number of Hands employed at any one time during the Year.	Average day's wages for a Skilled Mechanic.	Average day's wages for an Ordinary Laborer.	Total amount paid in wages during the Year.	Materials.	Products.
Agricultural implements...........	58	$1,085,530	1075	$2·06	$1·26	$235,335	$559,861	$1,148,872
Boots and shoes........................	543	477,077	1025	1·76	1·23	253,681	445,443	1,179,811
Bricks and tiles.........................	276	474,614	2760	2·08	1·17	370,929	227,637	935,507
Carpentering and building	374	531,660	2664	2·06	1·34	536,924	1,197,845	2,175,346
Cheese and butter......................	237	742,633	897	1·50	·95	127,430	1,087,645	1,555,188
Flouring and grist-mill products	701	7,950,560	3025	2·09	1·14	845,714	16,567,552	21,062,744
Lumber, sawn and planed.........	332	5,035,440	5886	1·88	1·23	1,399,779	3,808,696	6,401,940
Printing and publishing......	151	1,150,786	1384	2·00	1·17	509,529	525,536	1,431,589

Communication.—For means of communication and transportation Iowa is dependent almost entirely upon its railroads and its two bounding rivers. It has no canals, if we except the short one around the Des Moines rapids.

In 1880 there were forty-five railroads, working 4779 miles of track, with a total capital stock of $60,000,000, and a funded debt of $44,400,000. The total amount invested in railroads exceeded $100,000,000. The total gross earnings of the companies from passengers, freight, and mails were $5,218,000, of which $1,415,000 or 27 per cent. were net earnings. This is but $2\frac{3}{10}$ per cent. on the capital stock.

Banks.—According to the report for 1880 of the controller of the currency, there were in operation in Iowa 75 national banks, having a capital of $5,837,000, and an outstanding circulation of $4,697,314; 60 State banks and trust companies, with a capital of $2,521,985, holding $6,100,367 of deposits; 245 private bankers, representing a capital of $2,583,754, with deposits amounting to $7,017,806; and 4 savings banks, with a capital of $48,167, having deposits amounting to $208,018.

Administration.—As in the other States, the governmental power is divided among three departments, known as the executive, legislative, and judicial.

The officers of the executive department are the governor, lieutenant-governor, secretary of state, auditor, treasurer, superintendent of public instruction, and register of the State land office. All these officers are elected by the people, the term of office being in each case two years. No one is eligible for the office of governor or lieutenant-governor who is less than thirty years of age, or has not been a citizen of the United States and of the State for at least two years. The governor is commander-in-chief of the militia. He has the power of filling vacancies in office in cases for which the law does not otherwise provide, of calling the general assembly to meet in extra session, of vetoing laws passed by the general assembly, and of pardoning persons convicted of any crime excepting treason. The lieutenant-governor is *ex officio* president of the State senate; and, in the event of the death, resignation, or removal of the governor, he assumes his office.

The legislative department is vested in the general assembly, which consists of a senate and house of representatives. The former consists of not more than 50 senators, who are elected for terms of four years. Each senator must be at least twenty-five years of age, and must be a citizen of the State. The house of representatives consists of not more that 100 representatives. Their term of office is two years. A representative must have attained the age of twenty-one years. The general assembly meets at Des Moines (which since 1857 has been the capital), and holds a regular session once in two years.

The judicial department comprises a supreme court and district and circuit courts. Its officers are the judges of the several courts, clerk and reporter of the supreme court, attorney-general and district attorneys, all of whom are elected by the people. The supreme court consists of four judges, whose term of office is six years. The senior in office is the chief justice. The State is divided into a certain number of judicial districts, in each of which are elected every four years a judge of the district and of the circuit court and a district attorney. The latter is the prosecuting attorney for his district.

The representation of the State in the national congress consists of two senators, chosen by joint ballot of the two houses of the general assembly, and of nine representatives, elected directly by the people of the congressional districts.

The State is divided into ninety-nine counties. Their officers are all elected by the people, and the tenure of office is two years. They are—three, five, or seven supervisors (who collectively form a "board of supervisors"), an auditor, a clerk of the district and circuit courts, a sheriff, treasurer, recorder, superintendent of schools, coroner, and surveyor. The board of supervisors have authority over the property of the county, levy State and county taxes, and keep in repair roads and bridges. Each county is divided into civil townships, which are in most cases 6 miles square, corresponding with the congressional or survey townships of the general land system. Each township is under a civil government, administered by three trustees, a clerk, an assessor of taxes, and two or more justices of the peace and constables. All these officers are elected by the people, and all, with the exception of the justices of the peace, whose term is two years, serve for one year only. The trustees are the general managers of the affairs of the township. They are the judges of election, and have charge of fences and roads, and the care of the poor. Cities and towns, when incorporated, are not removed from the jurisdiction of the township officers.

Value of Property.—The preliminary results of the tenth census (1880) show the following figures regarding the wealth, debt, and taxation of the State:—

Assessed valuation of real estate	$296,254,342
" " personal property	101,268,422
Total assessed valuation	397,522,764
Amount of State tax	827,305
" county tax	4,280,091
State debt in 1879	$545,435
Bonded debt of counties	2,607,211
All other debt "	325,165

Judging from returns of true valuation of real estate from a few counties, scattered over the State, the true valuation of real estate must be not far from $900,000,000. It is impossible to make an estimate of the true valuation of personal property.

Education.—The State is divided into school districts, each civil township constituting one, with such incorporated cities and towns as may so elect. The support of the educational system is derived from the proceeds from all sales of State lands, 5 per cent. of all proceeds from sales of land belonging to the general Government within the State, a county tax of not less than 1 mill nor more than 2½ mills on the dollar, and a district tax of not more than 1½ per cent. upon the assessed valuation of the property within the school district. Besides these, there are several other minor sources of revenue. The amount of the school district tax for 1880 was $3,704,465, and the county tax for schools, $409,110, giving a total taxation for support of schools of $4,113,575. The total valuation of school property is estimated at $12,197,396. The total school district debt, all which is bonded, is $1,125,138. The schools are graded, and classified as primary, intermediate, grammar, and high schools. The law permits a high school in each county.

The State supports one university, located at Iowa City. It comprises academical, normal, medical, and law departments. The State also supports a school of agriculture and the mechanical arts, located near Ames, in Story county. There are also several colleges supported by religious denominations, the greater number of them belonging to the Methodists, theological seminaries, and a college under the direction of the Norwegian Luther Synod.

Population.—The inhabitants of the State in 1880 numbered 1,624,620, a gain of 36 per cent. on the number of 1870. The following tables show the growth of the population since 1840, and give details of its distribution in 1870 and 1880:—

	White.	Colored.	Total.	Increase per cent.
1840	42,924	188	43,112	
1850	191,881	333	192,214	346
1860	673,779	1069	674,913	251
1870	1,188,207	5813	1,194,020	77
1880	1,614,510	9953	1,624,620	36

	1880.	Percentage.	1870.	Percentage.
Males	848,234	52	625,917	52½
Females	776,386	48	568,103	47½
Natives	1,363,132	84	989,328	83
Foreigners	261,488	16	204,692	17

The density of the population is 30 inhabitants per square mile. Excluding the cities of 10,000 inhabitants and upwards (the urban population), this density is reduced to 27.

The principal cities of the State, with their population in 1880, are as follows:—

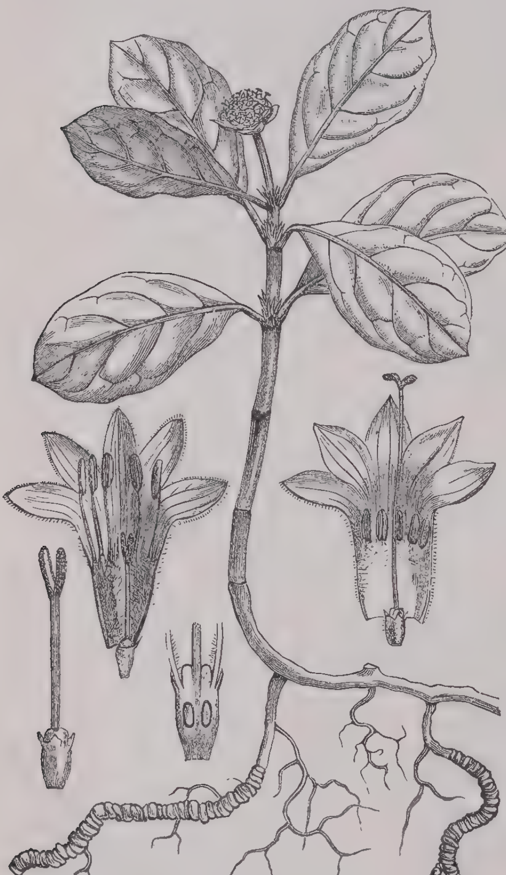
Des Moines	22,408	Keokuk	12,117
Dubuque	22,254	Cedar Rapids	10,104
Davenport	21,834	Clinton	9,052
Burlington	19,450	Ottumwa	9,004
Council Bluffs	18,059	Muscatine(estimated)	8,294

History.—Iowa was originally a part of the Louisiana purchase. In 1834 all that part of the United States lying west of the Mississippi river and north of Missouri, including the present area of Iowa, was placed under the jurisdiction of the Territory of Michigan, and two years later the Territory of Wisconsin was created, including what is now Iowa. In 1838 Iowa itself was made a Territory, and on December 28, 1846, it was admitted to the Union as a State. At the time of the Louisiana purchase, this region was occupied by the Sioux, Sac and Fox, and Iowa tribes of Indians. The first white settlements within the State were made along the Mississippi in 1833,—Fort Madison, Burlington, and Dubuque being the first points occupied. From these points settlement spread westward, and the growth of the Territory and State has from that time been rapid and steady. (H. G.*)

IOWA CITY, the capital of Johnson County, Iowa, and till 1857 the seat of the State Government, is situated on the Iowa river, and on the Chicago, Rock Island, and Pacific Railroad, 130 miles east of Des

Moines. It is the seat of the State university, which since 1857 has been open to both sexes, and holds a high position among western colleges, both as regards methods of study and the number of students in attendance. The population, which in 1870 was 5914, numbered 7123 in 1880.

IPECACUANHA. The root used in medicine under this name is obtained from *Cephaelis Ipecacuanha*, A. Rich., a small shrubby plant of the natural order *Cinchonaceæ*. It is a native of Brazil, growing in clumps or patches in moist shady forests from 8° to 22° S. lat., and is believed to extend to the Bolivian province of Chiquitos, and the valley of Cauca in New Granada. The drug of commerce is procured chiefly from the region lying between the towns of Cuyaba, Villa Bella, Villa Maria, and Diamantina in the province of Matto Grosso, and near the German colony of Philadelphia, north of Rio Janeiro. Ipecacuanha, although in common use in Brazil, was not employed in Europe previous to 1672. In France within a few years after that date it formed the chief ingredient in a remedy for dysentery, the secret of the composition of which was purchased by the French Government for 1000 louis d'or, and made public in 1688. The botanical source of ipecacuanha was not accurately known until 1800.



Ipecacuanha Plant.

The mode of obtaining the root is thus described by Weddell. The collector or *poayero* grasps the whole of the stems of the *poaya* or ipecacuanha plant in one hand, and loosens the roots by inserting a stick obliquely under them, to which is given a see-saw motion; the adhering soil is then shaken off, and the root placed in a bag. A poayero collects on the average about 10 to 12 ℔ of the root in a day, but sometimes as much as 30 ℔, or as little as 6 ℔ or 8 ℔. The root requires to be dried rapidly; it is therefore spread out in the sunshine as much as possible, and at night is covered over to shield it from the dew. In about three days, under favorable circumstances, it becomes dry, and is then broken up, sifted to remove sand or dirt, and packed in "serons," or bales made of cowhide. The root is gathered during the whole of the year, but in less quantity during the rainy season on account of the difficulty of drying the root. As imported, about three packages out of four are damaged by sea-water or damp. The root appears to be possessed of very great vitality, for in 1869 M'Nab, the late curator of the Botanical Gardens of Edinburgh, discovered that so small a portion as $\frac{1}{16}$ of an inch of the annulated root, placed in suitable soil, would throw out a leaf-bud and develop into a fresh plant, while Lindsay, a gardener in the same establishment, proved that even the leaf-stalk is capable of producing roots and buds; hence there is but little probability of the plant being destroyed in its native habitat. The great value of the drug in dysentery, and its rapid increase in price from an average of 2s. 9½d. per ℔ in 1850 to about 8s. 9d. per ℔ in 1870, led to attempts to acclimatize the plant in India, which, however, have not hitherto proved to be a commercial success, owing to the difficulty of finding suitable spots for its cultivation, and to its slowness of growth. Like other dimorphic plants, ipecacuanha ripens seeds best when cross-fertilized, and presents various forms. Two of these have been described by Professor Balfour of Edinburgh, one distinguished by having a woody stem, firm elliptic or oval leaves, with wavy margins and few hairs, and the other by an herbaceous stem, and leaves less coriaceous in texture, more hairy, and not wavy at the margins. This diversity of form is most apparent in young plants and tends to disappear with age.

Ipecacuanha root occurs in pieces about 2 or 3 lines in thickness, of a grayish-brown or reddish-brown tint externally, having a ringed or annulated surface, and exhibiting a white or grayish interior and a hard wiry centre. It has a faint rather musty odor and a bitterish taste. It is usually mixed with more or less of the slender subterranean stem, which has a very thin bark, and is thus easily distinguished from the root. The activity of the drug resides chiefly in the cortical portion, and hence the presence of the stem diminishes its value. The variety imported from New Granada and known as Cartagena ipecacuanha differs only in its larger size and in being less conspicuously annulated. Ipecacuanha owes its properties to the presence of rather less than 1 per cent. of the alkaloid emetine, which, with the exception of traces, occurs only in the cortical portion of the root. The formula assigned to emetine has been variously stated by different chemists, that published by Lefort and Wurtz in 1877 is $C_{28}H_{40}N_2O_5$. Emetine is a white powder, turning brown on exposure to light, and softening at 70° C. (158° Fahr.). It is precipitated from its solution by tannin and nitrate of potassium, and is soluble in chloroform, but only slightly so in ether. A solution containing only $\frac{1}{6000}$ part of emetine has been shown by Power to become of an intense and permanent yellow color when treated with a solution of chlorinated lime and a little acetic acid. Emetine exists in the root in combination with ipecacuanhic acid, which according to Reich is a glucoside. It is amorphous, bitter, and very hygroscopic. The root contains also about 37 per cent. of starch, a large quantity of pectin, and small proportions of resin, fat, albumen, and fermentable and crystallizable sugar.

Ipecacuanha is one of the safest and most valuable emetics, being more suitable for administering to children than any other. The amount required to produce its effect varies considerably, children as a rule being more tolerant than adults: according to Ringer, thirty grains is the average dose for an adult, twenty grains for young children. Its action is rather slow, taking place in from 20 minutes to half an hour after ingestion. Minute quantities of the drug, on the contrary, such as drop doses of ipecacuanha wine every hour or three times a day, according to the urgency of the case, have the effect of checking vomiting arising from natural causes. The nauseating and emetic properties of ipecacuanha are believed to be due to its influencing the peripheral terminations of the pneumogastric nerve, since it produces vomiting even if injected into the blood. In nauseating doses it acts both as a diaphoretic and antispasmodic. It is also a stimulant or irritant of the mucous membranes, and is hence classed as an expectorant, and used successfully in cough, bronchitis, gastric catarrh, and diarrhœa. Some individuals are so sensitive to the action of ipecacuanha as to suffer, even on smelling the drug on entering a room where it is kept, all the symptoms of coryza, hay fever, or bronchitis. In large doses of from 60 to 90 grains, repeated if required in 10 or 12 hours,—the patient lying on his back to prevent sickness or nausea,—it is found to be one of the most valuable remedies in dysentery, especially in the epidemic and sporadic forms met with in tropical and malarious countries. Externally applied in the form of ointment, ipecacuanha causes considerable irritation, followed by the appearance of pustules and ulceration. In doses of one-eighth to one-sixth of a grain it acts as a stomachic, and probably increases the gastric secretions.

Other plants to which the name of ipecacuanha has been popularly applied are American Ipecacuanha (*Gillenia stipulacea*, Spreng.), Wild Ipecacuanha (*Euphorbia Ipecacuanha*, L.), Bastard Ipecacuanha (*Asclepias curassavica*, L.), Guiana Ipecacuanha (*Boerhavia decumbens*, Vahl), Venezuela Ipecacuanha (*Sarcostemma glaucum*, H. B.), and Ipecacuanha des Allemands (*Vincetoxicum officinale*, Moench.). All these possess emetic properties to a greater or less degree.

The term *poaya* is applied in Brazil to emetic roots of several genera belonging to the natural orders *Cinchonaceæ*, *Violaceæ*, and *Polygalaceæ*, and hence several different roots have from time to time been sent over to England as ipecacuanha; but none of them possesses the ringed or annulated appearance of the true drug. Of these the roots of *Ionidium Ipecacuanha*, Vent., *Richardsonia scabra*, St. Hil., and *Psychotria emetica*, Mutis, are those which have most frequently been exported from Brazil or New Granada.

IPEK (?12,000) (Slavonic, *Petcha*; Albanian, *Peja*; Latin, *Pescium*), a town of Upper Albania, in the Turkish eyalet of Uskub, situated in the upper valley of the Drin between the mountains Peklen and Koprionik. A small stream, bearing like several others in the Balkan peninsula the name of Bistritza (the bright or clear), flows through the town. On one of the neighboring heights is situated the monastery of Ipek, founded by Archbishop Arsenius in the 13th century, and famous as the ancient seat of the patriarch of the Servian Church. The buildings are surrounded by thick walls, and comprise a large central church (Our Lady's), and two side chapels (the Martyrs and St. Demetrius), each surmounted by a leaden cupola. The church dates from the 16th and 17th centuries. Among its numerous objects of interest are the body of Archbishop Nicodemus, the white marble tombs of Arsenius and other chiefs of the Servian Church, and the white marble throne on which the patriarchs were crowned. The side chapels have stained glass windows. According to some authorities, Ipek occupies the site of Dioclea, destroyed by the Bulgarians in the 11th century. In the Turkish administration it is the seat of a pasha with two tails, and at one time the pashalik had become almost an hereditary government. The population of the town was calculated by Boué (1838, 1845) at 8000 and by Dr. Müller (1844) at 12,000. Jourishitch, the Servian author, states the number of houses at 4000. In the recent troubles of Turkey Ipek has suffered, and in 1876 the Turkish officials closed the monastery.

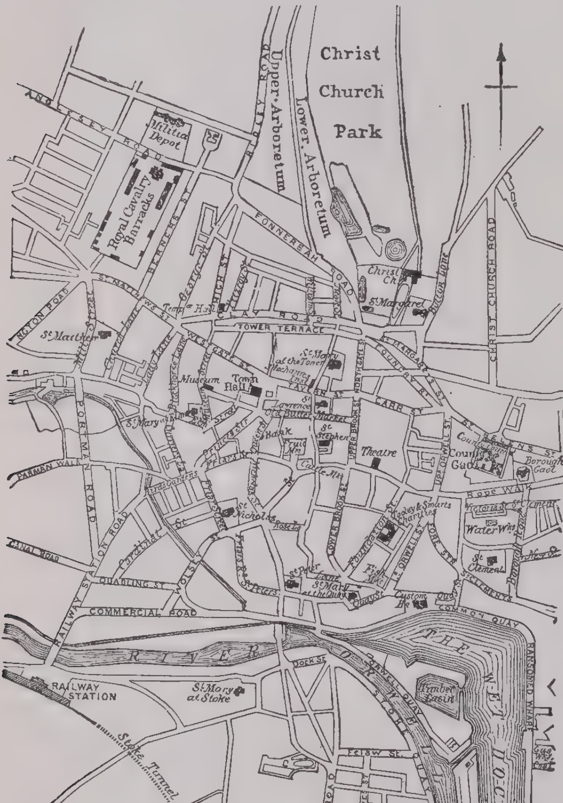
IPHICRATES, an Athenian general who flourished in the earlier half of the 4th century B. C., owes his fame as much to the improvements which he made in the accoutrements of the peltasts or light-armed troops as to his numerous victories gained by their aid. Increasing the length of their javelins and swords, substituting linen corselets for their heavy coats-of-mail, and introducing the use of light shoes, called after him *Iphicratides*, he increased greatly the rapidity with which these troops could make the sudden forays that were so common in the military tactics of the time. With his peltasts Iphicrates seriously injured the allies of the Lacedæmonians in the Corinthian war, and in 392 succeeded in dealing a heavy blow at once to the vanity and the prestige of the Spartans, by almost annihilating a body of their famous hoplites. Following up his success, he took city after city for the Athenians; but his arrogance procured his transfer from Corinth to the Hellespont, whither, however, his success followed him. About 378 he accepted a command under the Persians in Egypt, and on his return thence to Athens commanded an expedition in 373 for the relief of Corcyra, which was menaced by the Lacedæmonians. On the peace of 371, Iphicrates seems to have returned to Thrace, and somewhat tarnished his fame by siding with his father-in-law, King Cotys, in a war against Athens for the possession of the entire Chersonese. The Athenians, however, soon pardoned him and gave him a joint command in the social war. For his conduct in this position he was impeached; after his acquittal he lived quietly at Athens. The date of his death is unknown.

See Rehdantz, *Vitæ Iphicratis, Chabriæ et Timothei.*

IPHIGENEIA is the heroine of several famous Greek legends. She is generally said to be the daughter of Agamemnon, and is also called Iphianassa, though the two are distinguished by Sophocles and by the writer of the *Cypria*. Agamemnon had offended Artemis, who therefore prevented the Greek fleet from sailing for Troy, and could be appeased only by the sacrifice of his daughter. According to some accounts the sacrifice was completed, according to others Artemis carried away the maiden to be her priestess in the Tauric Chersonese, and substituted for her a hind. In this new country it was her duty to sacrifice to the goddess all strangers; and as Orestes came in search of her she was about to sacrifice him, when a happy recognition took place. These legends show how closely the heroine is associated with the cultus of Artemis, and with the human sacrifices which accompanied it in older times before the Hellenic spirit had modified the barbarism of this borrowed religion. They bring into connection the different places in which this goddess was worshipped; and, as Attica was one of her chief seats, Iphigeneia is sometimes called a daughter of Theseus. At Comana in Cappadocia, one of the chief homes of the goddess in her more barbaric form, there was a priestly family Orestiadæ; and Iphigeneia and Orestes are named as the founders of Artemis worship in Sparta and Attica, as well as in many parts of Asia Minor and Italy (see Preller, *Griech. Mythol.*, 3d ed., i. 250). At Hermione Artemis was worshipped with the epithet Iphigeneia,—this showing the heroine to be in the last resort a form of that goddess. Iphigeneia is a favorite subject in Greek literature and art. She is the heroine of two plays of Euripides; but none of the many other tragedies founded on her story have been preserved. In vase paintings she frequently occurs; and the picture by Timanthes representing Agamemnon hiding his face at her sacrifice was one of the famous works of antiquity.

IPSWICH (50,000), Old Eng. *Gippeswic*, the county town of Suffolk, 68 miles north-east of London by rail, stands on a gentle ascent above the left bank of the Gipping, which widens here into the Orwell estuary. Its lower and older portion, irregularly built, retains some curious specimens of ancient domestic architecture, as Sparrowe's House (1567), with quaint emblematic mouldings of Charles II.'s reign, Archdeacon's Place (1471), and Wolsey's Gateway (1528), sole relic this of one of those "twins of learning," the colleges of Christ Church and Ipswich. The public buildings, however, are one and all of them modern. The town-hall (1868) is an imposing edifice in the Venetian style, surmounted by a clock-tower 120 feet high, and beautified with statues and medallions. Close by, and similar in style, are the post-office (1880) and the new corn-exchange (1880–81), and a second good group is formed by the new museum and fine art gallery (1880–81), the former of which, founded in 1847, has a splendid collection of red crag fossils. Other buildings are the East Suffolk Hospital (1836–69), militia artillery barracks (1855), custom-house (1845), mechanics' institute (1824; greatly enlarged 1877), working men's college (1862), public hall (1868), and a little theatre, where Garrick made his début in 1740. The grammar school, dating from at least 1477, was last refounded by Queen Elizabeth in 1565, and was rebuilt in 1851 on the northern outskirts of the town, the Prince Consort laying the foundation stone. It is a red brick Tudor pile, with a pretty chapel, has 6 masters and 85 boys, and is endowed with 11 scholarships of an aggregate yearly value of £302. Fourteen board schools had an average attendance of 2426 in May, 1880, when there were twenty-two other elementary schools, attended by 3130 children. The older of the sixteen churches are all of them towered flint-work structures, wholly or mainly Perpendicular in style, with the exception of St. Peter's (restored and enlarged in 1877), which is Decorated. They include St. Margaret's (restored 1846–74), with a beautiful oak Tudor roof, elaborately painted *temp.* William and Mary; St. Matthews (restored 1860), St. Lawrence (1431; restored 1858); and St. Clement's (restored 1860–80), containing the tomb of Eldred, an early circumnavigator. St. Michael's (1880) is a wholly new erection in Early English style, and three other churches have practically been rebuilt—St. Mary-le-Tower (1863–66), rich in oak carving and painted glass, with a tower and spire 176 feet high, and a peal of twelve bells; St. Helen's (1877–78), also with a spire; and St. Mary (1871) at Stoke, a suburb south of the Gipping. Of non-established places of worship the Roman Catholic church of St. Pancras (1863) is the most noticeable, a late First Pointed edifice with a richly carved reredos and a lofty flèche. Ipswich has two finely planted arboretums, the upper one of which is public; alongside stretches Christ Church park, with its picturesque Tudor mansion (1549). There are shady walks too, between the river and a wet dock, which, formed in 1842 at a cost of £130,000, covers 32 acres, and admitted vessels drawing 14 feet. Under an Act obtained in 1877 the commissioners have expended £80,000 more in making a new entrance lock, to admit vessels drawing 18 feet, in erecting public warehouses, and in deepening and improving the river.



Plan of Ipswich.

In 1879, 264 vessels of 54,353 tons entered from, and 89 of 11,406 tons cleared to, foreign countries and British possessions; coastwise there entered 2405 of 152,161, and cleared 1792 of 118,624 tons. There were 125 vessels of 9779 tons, besides 23 fishing boats, registered as belonging to the port on 31st December of that year, in which the customs revenue amounted to £20,828, the chief imports being coal (51,720 tons), linseed, cotton seed, maize, barley, iron, and iron pyrites; the exports, wheat, malt, flour, artificial manures, and agricultural implements. The last are manufactured at the Orwell Works (1785) of Ransomes, Sims, & Head, the greatest in the world, covering 13 acres, and employing over 1400 hands. Shipbuilding (27 vessels of 1965 tons during 1875–79), brewing, tanning, and the manufacture of manure from coprolites, and of silk, flax, ropes, and artificial stone, are the leading industries. Ipswich returns two members to parliament. The borough has an area of 8192 acres, The population, which in 1871 was 42,947, had increased in 1881 to 50,213.

A pavement found in Castle Field in 1854 establishes the presence of the Romans, but Ipswich is first mentioned in history as having been plundered by Northmen in 991 and 1000. Lying out of the course of events, it has played no conspicuous part, and the chief incidents in its history are the granting of its earliest charter by John (1199); the visits of Edward I. (1297), Edward III. (1350), Elizabeth (1561, 1565, and 1578), and George II. (1737); the meeting of the British Association (1851) and of the British Archæological Association (1864). Thomas Wolsey (1471–1530), William Butler (1535–1618), Bishop Ralph Brownrigg (1592–1659), Clara Reeve (1738–1803), and Mrs. Trimmer (1741–1810) were natives; and Gainesborough, a resident from 1747 to 1759, has given his name to a beautiful lane above the "princely" Orwell. See G. R. Clarke's *History of Ipswich*, Ipswich, 1830.

IPSWICH (7734), the second most important town of Queensland, Australia, is built on the south side of the river Bremer at the head of navigation, about 24 miles in a westerly direction from Brisbane, in 27° 35′

S. lat. and 152° 50′ E. long. It is the centre of a rich pastoral and agricultural district, the principal product being maize. Coal is worked on the banks of the Bremer and the Brisbane, and there is a woollen factory in the town. A court-house, a hospital, a lunatic asylum, a grammar school, opened in 1863, and a school of arts are among the public buildings. The first sale of crownlands took place on October 11, 1843; and the first steamer between Brisbane and Ipswich was run June 29, 1846. It was in 1860 that the town was incorporated as a municipality, and in the same year was held the first session of the supreme court. The railway to Brisbane was opened in 1875. The value of ratable property is estimated at about £350,000. In 1871 the population of Ipswich was 4820; in 1876, including the suburbs, it was 7734.

IQUIQUE, a seaport town of Peru, in the department of Tarapaca, in 20° 12′ S. lat. In the twenty-five years from 1850 to 1875 it rose from a mere fishing village to be a place of from 18,000 to 20,000 inhabitants. This rapid growth was solely the result of the trade in the nitrate of soda which is found in exhaustless abundance in the neighboring country, and of which during the five years 1874 to 1878 there was annually exported from the province, by way of Iquique, Mejillones, Junin, and Pisagua, an average of 276,811 tons. About 60 or 70 tons of iodine are also manufactured in the nitrate of soda factories, varying in proof from 95 to 98 per cent. There entered and cleared in 1877 253 vessels, of which 142 were English, the total burden being 138,054 tons. As there is no cultivable land in the vicinity, all provisions have to be imported. In 1875 the town was laid waste by a conflagration; and it had hardly begun to recover from this disaster when it was visited in 1877 by a series of earthquakes. The wooden houses which fell at the first shock took fire, and while the firemen were endeavoring to extinguish the flames a huge wave rushed in and carried off their engines. The people suffered severely both from hunger and thirst, as the principal store and the water condensers were both destroyed. The total damage was estimated at £800,000. In 1878 there were only 7000 or 8000 people in the town, which, however, has been rebuilt with greater attention to solidity of architecture and regularity of plan.

IRAK ADJEMI (*i.e.*, Persian Irak), also called Jebal (Arabic, mountains) and Kohistan (Hindustani, mountain-land), is the most important of the eleven provinces of Persia, comprising the larger part of the western half of the country, or upwards of 138,280 square miles. To the north lie Azerbijan, Ghilan, and Mazanderan, to the east Khorasan, to the south Farsistan and Khuzistan, and to the west Ardilan and Luristan. The mountains for the most part run west and east, or north-west and south-east. Among the important valleys are those of Hamadan, Ispahan, and Yezdikhast. The principal river—though it only belongs to Irak Adjemi in the middle part of its course—is the Kizil Uezen or Sefid Rud, which drains about 25,000 square miles of country, rising between Hamadan and Tabriz, in that part of the Kurdistan highlands which bears the name of Besch Parmak or Pentchangusht (Five-Finger Mountain), flowing north-north-east and then east to its junction with the Hasht Rud, and finally breaking through the Elburz range and finding its way to the Caspian. The rest of the rivers for the most part flow towards the Great Salt Desert, which forms part of the wide eastern plain that stretches eastward into Khorasan. The following are points whose position has been fixed. Teheran, the capital, 35° 40′ 30″ N. lat., 51° 24′ 54″ E. long.; Kum, 34° 39′ N. lat., 50° 53′ 54″ E. long.; Kushan, 34° N. lat., 51° 26′ 39″ E. long.; Ispahan, 32° 37′ 30″ N. lat., and 51° 39′ E. long. The name Irak Adjemi is a modern one, and Reynaud confesses that he knows no other origin of its use than the fact that the Seljukids who reigned over Irak and bore the title of Sultan el Irak were also rulers of the Jebal. The country corresponds in large part to the ancient Media.

IRAK ARABI, or Irak el Arabi, to which the name Irak is more properly applied, is the district between the Tigris and Euphrates, and from the Euphrates west to the desert, its northern limit being from Anah on the Euphrates to Tekrit on the Tigris. It corresponds to the land of Chaldæa or Lower Mesopotamia. There is a town Irak in the district, about 20 miles east of the Euphrates.

IRAWADI, or Irrawaddy, the principal river in the province of British Burmah, traversing the Pegu division from north to south. The Irawadi is formed by the junction of two streams whose source is as yet unknown, in about 26° N. lat. The chief tributaries are the Mogoung, from the westward, which throws its water into the main stream (here 600 yards wide) in 24° 50′ N. lat. and the Shwe lí and Kyeng-dweng. Shortly after leaving the mouth of the Mogoung it enters the first or upper defile. Here the current is very rapid, and the return waters occasion violent eddies and whirlpools. When the river is at its lowest, no bottom is found even at 40 fathoms. After receiving the Tapeng from the east, it enters the second defile, which is exceedingly picturesque, the stream winding in perfect stillness under high bare rocks rising sheer out of the water. Farther down the Irawadi, and not far from Mandalay, is the third or lowest defile. The banks are covered at this point with dense vegetation, and slope down to the water's edge; at places appear almost perpendicular but wooded heights. The course of the Irawadi after receiving the waters of the Myitnge and Tsagaing, as far as 17° N. lat., is exceedingly tortuous; the British frontier is crossed in 19° 29′ 3″ N. lat., 95° 15′ E. long., the breadth of the river here being ¾ mile; about 11 miles lower down it is nearly 3 miles broad. At Akouk-toung, where a spur of the Arakan hills ends in a precipice 300 feet high, the river enters the delta, the hills giving place to low alluvial plains, now protected on the west by embankments. From 17° N. lat. the Irawadi divides and subdivides, converting the lower portion of its valley into a network of intercommunicating tidal creeks. It reaches the sea in 15° 50′ N. lat. and 95° 8′ E. long., by nine principal mouths. The only ones used by sea-going ships are the Bassein and Rangoon mouths. The area of the catchment basin of the Irawadi is 158,000 square miles; its total length from its known source to the sea is about 900 miles, the last 240 of which are in British territory. As far down as Akouk-toung in Henzada district its bed is rocky, but below this sandy and muddy. It is full of islands and sandbanks: its waters are extremely muddy, and the mud is carried far out to sea. The river commences to rise in March; about June it rises rapidly, and attains its maximum height about September. The total flood discharge for 1877 was 466,120,288,940 metre tons of 37 cubic feet. The river is navigable at all seasons by steamers of light draught as high as the first defile, and during the dry season for steamers drawing 6 feet as far as the frontier. The chief tributaries of the Irawadi in British territory are the Tha-htún (or Theng-dún), the Tha-de, and Thai-lai-dan from the west; and the Kye-ní, Bhwotlay, and Na-weng from the east. Below Akouk-toung on the west and Prome on the east the Irawadi receives no tributaries of any importance.

The broad channel of the Irawadi has always been the sole means of communication between the interior and the seaboard. From time immemorial the precious stones, minerals, etc., of Upper Burmah, Siam, and the Chinese frontier provinces have been brought down by this route. At the present day the great bulk of the trade is in the hands of the "Irrawaddy Flotilla Company," an important English carrying firm; but native boats still maintain a strenuous competition. The flotilla of the company consists of about sixty vessels, including both steamers and flats. They employ about 1770 hands, European and native, and distribute in wages upwards of £50,000 a year. Their headquarters are at Rangoon, whence steamers run twice a week to Bassein, and also to Mandalay. The latter service is continued twice a month to Bhamo, about 1000 miles from the sea. The principal articles carried up stream are Manchester piece goods, rice, salt, hardware, and silk. The articles carried down stream are raw cotton, cutch, india-rubber, jade, spices, precious stones, timber, earth-oil, and dry crops, such as wheat and pease. The value of the trade either way is roughly estimated at about 1½ millions sterling. The total number of native boats on the Irawadi is returned at about 8000. They carry a large proportion of the heavy articles of commerce, especially cutch and earth-oil.

IRBIT, a town of European Russia in the government of Perm, 70 miles north-east of Ekaterinburg, at the confluence of the Irbit with the Nitza, a sub-tributary of the Obi. Though the St. Petersburg Calendar for 1878 gives the permanent population as only 4212 (in 1860 the number was 3408), it is one of the most important trade centres of northern Russia, and during its great fair (February 1–13 to March 1–13) it is visited by upwards of 20,000 people. Among its public buildings are a theatre, an exchange, a bank (established in 1849, with a capital of 30,000 roubles), and a district school. Irbit was originally founded by Tartars in 1633, but the discovery of iron ore in the neighborhood soon attracted Russian settlers. The assistance which the inhabitants rendered in the suppression of the Pugatcheff rebellion was rewarded by Catherine granting Irbit the rank of a town in 1775. In 1781 it was made a district town of Perm. The right of holding the fair was bestowed by Michael Theodorovitch as early as 1643, and from 1695 the customs which had previously been collected at Verkhoturya were taken at Irbit itself.

In 1829 the value of the wares brought to market amounted to 10,888,155 roubles (£1,723,916), and these were sold to the value of 7,537,489. In 1861 the corresponding figures were 51,204,000 roubles and 39,397,500. In 1859 the principal items were (*a*) of Russian goods: leather and skins, 6,780,000 roubles; furs, 4,750,000; copper and iron, 1,252,000; grain, salt, meat, and fish, 1,207,000; fruit and groceries, 1,115,000; wooden wares, 1,040,000; (*b*) of European wares: cotton, woollen, and silk, 12,087,000; sugar, 2,650,000; groceries 860,000; (*c*) of Asiatic goods: tea, 29,500,000. In 1880 the fur trade was especially active, no fewer than 3,550,000 Siberian furs and 110,100 Russian furs being brought to market. The tea, on the other hand, did not go beyond the value of 5½ million roubles. There is a horse fair at Irbit, October 28th (September 10th), when old horses are disposed of by Tobolsk and Tyumen Tartars. The Irbit iron-works are situated 40 miles from the town, on the banks of the river Irbit, below the confluence of the Shaitanka, which flows out of Irbit lake, a sheet of water nearly 4 miles long and 2½ miles broad. The inhabitants of the spot numbered 1822 in 1869 (861 men and 961 women). In 1873 the output of pig iron was about 2000 tons. The Irbit post-road leaves the great Siberian road at Kamnishloff, 73 miles from the town.

IRELAND.

PART I.—GEOGRAPHY AND STATISTICS.

IRELAND, a large island to the west of Great Britain, and along with it forming the United Kingdom, extends from 51° 26′ to 55° 21′ N. lat., and from 5° 25′ to 10° 30′ W. long. It is encircled by the Atlantic Ocean, and on the east is separated from Great Britain towards the north by the North Channel, whose width at the narrowest part, between the Mull of Cantyre and Torr Head, is only 13½ miles; in the centre by the Irish Sea, whose width is 130 miles; and in the south by St. George's Channel, which has a width of 69 miles between Dublin and Holyhead, and of 47 miles at its southern extremity. The island has the form of an irregular rhomboid, the largest diagonal of which, from Torr Head in the north-east to Mizen Head in the south-west, measures 302 miles. The greatest breadth of the island is 174 miles, and the average breadth about 110 miles. The total area comprises 32,535 square miles, or 20,822,494 acres. Territorially it is divided into 4 provinces—Leinster, Munster, Ulster, and Connaught—and 32 counties, the number of counties included in the different provinces being 12, 6, 9, and 5 respectively. These 32 counties are divided into 316 baronies, comprising 2532 parishes, which are further divided into townlands or ploughlands numbering about 60,760, with an average size of over 300 acres each. Table I. shows the area and distribution of land by provinces and counties in 1880.

Geology.—The central part of Ireland is occupied by a great undulating plain, whose highest elevation is 300 and average elevation about 200 feet. In the centre of the country, from Dublin Bay on the east to Galway Bay on the west, this plain stretches from shore to shore, but towards the south and north it is enclosed by an irregular semicircular belt of mountainous country. The surface of the plain is broken occasionally by isolated hills. Throughout nearly the whole of its extent it rests on the Carboniferous Limestone, and in several places there are remains of the Upper Carboniferous strata or Coal-measures, by which the Carboniferous Limestone was at one time overlaid, and which have been carried away during a vast period of denudation chiefly by the action of subaerial agents. The strata of limestone are nearly horizontal, except where they are contorted by local disturbances. In the central plain it is only occasionally that the limestone crops to the surface, as it is generally overlaid by boulder clay, the result of glacial action, by the middle sands and gravels formed on the bed of the shallow sea by which the plain was at one time occupied, or by the peat bogs resting on the beds of previous lakes. At one period the Carboniferous beds must have extended widely beyond their present limits, and have formed the surface strata of the uplands to the north-west and south-east. In the north-western highlands of Sligo, Leitrim, and Fermanagh they still form a lofty tableland, which occasionally rises into peaks about 2000 feet in height.

The mountain masses of Ireland are generally traversed by deep and narrow valleys running both north and south and east and west, and frequently giving rise to high and isolated peaks. The districts of Donegal and Derry in the north-west, and those of Galway and Mayo in the west, consist chiefly of metamorphosed Lower Silurian rocks, and are believed to form part of the same geological system as that of the Highlands of Scotland. Those of Donegal and Derry, lying between Donegal Bay and Lough Foyle, consist of granite, gneiss, and hornblendic and other schists, with crystalline limestones and quartzites. Their principal peaks are the isolated summit of Errigal (2466 feet) and Blue Stack (2219 feet). In West Galway and Mayo the rocks consist chiefly of quartzite, or of alternating beds of quartzite and granite or gneiss schist. They include the Twelve Pins of Connemara (2395 feet), Croagh Patrick on the shores of Clew Bay (2510 feet), the Nephin Beg mountains, and the Ox mountains. The range of hills between Killary Harbor and Lough Mask—the highest summit of which, Muilrea, has an elevation of 2688 feet—belongs to the Upper Silurian formation. The fact that these rocks do not share in the metamorphism of the Lower Silurian beds shows that

the alteration must have taken place at some time between the Lower Silurian and Upper Silurian periods. Rocks of Cambrian age occur in Wexford, Wicklow, and Dublin. The principal elevations of these districts are formed of granite, and belong to an earlier epoch than that of the Old Red Sandstone. The highest summit is Lugnaquilla (3039 feet), composed of altered Silurian rocks lying on the granite. In the south-western districts of Kerry, Cork, and Waterford, the mountains are composed of broad bands of Old Red Sandstone, the valleys being formed of narrow bands of Carboniferous rocks. The lie of the strata is nearly east and west, since they have been plicated by forces acting in a transverse direction, the time of disturbance being some unknown date between the Carboniferous and the Permian periods. This district includes the rugged range of Macgillicuddy's Reeks, which rise abruptly from the Carboniferous Limestone surrounding the Killarney lakes, and, occupying the greater part of the peninsula between Dingle Bay and Kenmare River, attain at Carntual a height of 3414 feet above sea-level. Many of the most conspicuous mountain groups in the southern half of the island consist of central cores of Silurian strata wrapped round with thick folds of Old Red Sandstone. Such are Slieve Aughty, Slieve Bernagh, the Silver Mine mountains, and Slievenaman in Clare and Tipperary, Galtymore in Limerick, which has an elevation of 3015 feet, and the Slieve Bloom mountains in Queen's county. The principal mountain groups in the north-east are the Carlingford mountains, composed of felspathic and pyroxenic rocks, and attaining in Slieve Foy a height of nearly 2000 feet; the Mourne mountains to the north of Carlingford Lough, composed of granite, with veins of basalt, felstone, mica trap, and porphyry, the highest summit being Slieve Donard (2796 feet); and the Slieve Croob mountains, to the north of the Mourne range, composed of granite of a much earlier origin. Both the Mourne and Carlingford mountains are of intrusive origin, and probably belong to the Permian period. A considerable extent of low country in Down, Armagh, and Cavan is occupied by Silurian rocks in the form of grits and slates. The estuary of Belfast Lough lies in Triassic rocks, containing beds of rock salt. Rocks of similar age extend west of Lough Neagh, and thence north to Lough Foyle. They are overlaid by Jurassic and Cretaceous strata, which, however, are almost wholly concealed under the great basalt flood of the north-eastern counties. The greater part of Antrim and the eastern portion of Derry are occupied by basalt rock forming an elevated plateau, for the most part bounded towards the sea by precipitous escarpments, consisting of Upper Greensand and Chalk, surmounted by the black basalt which, often crowning their summits, stands in striking contrast with the light-colored strata below. In some places, however, as at the Giant's Causeway, the Creta-

* Including 133,035 acres under the smaller streams and lakes.

ceous rocks disappear, and the basalt slopes gradually to the sea, displaying a series of terraces formed of hexagonal pillars, and occasionally separated by bands of volcanic ash.

Coast-Line.—Along the present coast-line there are to be seen in several places traces of ancient sea margins, the most continuous being those on the northern and eastern coasts, especially in county Antrim. Of still more ancient sea margins there are evidences in the terraces at the base or on the flanks of the mountains. The present coast-line, especially on the west and south, is very much indented by bays and inlets, which Hull, in his *Geology of Ireland*, attributes in many cases to the chemical action of the sea-water on the limestone rocks. On the south coast they most commonly run in a northerly direction with a westerly inclination at the upper end, and on the west coast the direction of the larger inlets is easterly, although several of the smaller ones run north, south, and north-east. Their troughs have mostly been excavated in the synclinal folds of the rocks, which therefore frequently project far into the sea in the form of high and bold headlands. On the northern coast the inlets generally run in a southerly or south-westerly direction. Most of those on the east coast have by the accumulation of sand been either wholly or partly formed into lagoons; and on the south-east coast the sea has made considerable encroachments on the land.

The principal inlets are—on the east coast Belfast Lough, Strangford Lough, Carlingford Lough, Dundalk Bay, Dublin Bay, and Wexford Harbor; on the south coast Waterford Harbor, Dungarvan Harbor, Youghal Bay, and Cork Harbor; on the south-west coast Roaring Water Bay, Dunmanus Bay, Bantry Bay, Kenmare River, and Dingle Bay; on the west coast Tralee Bay, the mouth of the Shannon, Galway Bay, Clew Bay, Blacksod Bay, Killala Bay, Sligo Bay, and Donegal Bay; and on the north coast Sheep Haven, Lough Swilly, and Lough Foyle. In all, Ireland possesses fourteen harbors suitable for the largest ships, seventeen for frigates, and over thirty for coasters, besides an immense number suitable for fishing-boats.

The islands of Ireland are small in size, and are situated near the mainland, most of them being formed of rocks from which, according to Hull, the adjoining Carboniferous strata had been denuded by the action of the sea-water. They are most numerous on the west coast, especially opposite Galway, Mayo, and Donegal. Off the Donegal coast the largest is Neish Aran. Separated from the mainland of Mayo by a narrow isthmus is Achill, the largest island of Ireland, and in Clew Bay there are an immense number of islets all formed of drift. An archipelago of granite rocks off the coast of Galway is formed of continuations of the mountains, and at the mouth of Galway Bay are the three islands of Aran, composed of Carboniferous Limestone. Among the picturesque stacks of rocks off the coast of Kerry the most notable are the Skellings. The largest islands opposite Cork are Dursey Island, Bear Island, and Clear Island, south of which is a picturesque rock called the Fastnet, on which there is a lighthouse. On the east coast the principal are Lambay Island, Innispatrick, and Ireland's Eye off county Dublin and Copeland Island at the mouth of Belfast Lough. On the northern coast the principal are Rathlin Island off Antrim, and Tory Island off Donegal.

Rivers and Canals.—Several of the rivers of Ireland, including the largest of them, have had their channels determined by a previous physical condition of the land surface, and must have been formed during a long period of denudation. Many of the valleys are dried-up river beds, and along various of the present river valleys traces of old river terraces may still be seen. In some cases the alterations of the courses by breaks and dislocations of the strata are of very recent occurrence. In the districts of Sligo and Fermanagh, as well as of Galway, Clare, Kerry, and Cork, the rivers and streams have frequently cut out subterraneous passages through the limestone, in some cases altogether disappearing; and along their courses *turloughs* or blind lakes, and abrupt deep holes called *sluggas* are frequently formed.

Owing to the moistness of the climate and the lie of the surface of the country, Ireland is more intersected by large rivers than England or Scotland, and it is a remarkable circumstance that in several cases there are groups of rivers with closely contiguous sources, which, however, flow in widely different directions. The largest river is the Shannon, which has its source in the Carboniferous mountains of Fermanagh and Leitrim, and flows southward through Lough Allen, Lough Ree, and Lough Dearg to Limerick, where it opens out into a wide estuary and takes a westerly course to the ocean. Up to Limerick, where it becomes tidal, it is navigable for large vessels, and for vessels of small tonnage it is navigable within 5 miles of Lough Allen. Its course above Lough Dearg is very sluggish, but from that lake to Limerick its descent is very rapid. Its total length is 240 miles, and it drains an area of 4544 square miles. The Suir, the Nore, and the Barrow, which have their sources not far from each other in the Slieve Bloom mountains, and unite at Waterford, drain together an area of 3400 square miles. The Suir is navigable for boats as far as to Clonmel, and the Nore to Innistioge. The Barrow, by means of a branch of the Grand Canal, forms a line of 120 miles of inland navigation between Dublin and Waterford. The other principal rivers, all of which are to some extent navigable, are—debouching on the west coast the Erne, the Moy, and the Corrib; on the south coast the Blackwater and the Lee; on the east coast the Lagan, the Boyne, the Liffey, and the Slaney; and on the north coast the Bann and the Foyle.

The Grand Canal, which with its various branches has a length of 165 miles, connects Dublin with the Shannon at Shannon Harbor; and the Royal Canal, with a length of 76 miles, connects Dublin with the Shannon at Cloondora. Lines of inland navigation, partly natural and partly artificial, connect Lough Neagh with Belfast, Newry, and Lough Erne. From the sea at Galway there is communication by Lough Mask and Lough Corrib to Lough Carra. Since the introduction of railways the passenger traffic on the canals has wholly ceased, but the goods traffic is still considerable.

Lakes.—Many lakes of considerable extent exist both in the mountainous and lowland districts of Ireland, and the number of small lakes is very great. Altogether the area covered by lakes amounts to 711 square miles, of which 287 are in Ulster, 305 in Connaught, 69 in Munster, and 50 in Leinster. Lough Neagh in Ulster is the largest inland lake in the United Kingdom, and has an area of 153 square miles, with a general depth of from 20 to 40 feet. Lough Erne in Fermanagh has a length of upwards of 40 miles, but a breadth of only 8 miles. Properly speaking, it consists of two lakes 5 miles apart and connected by a river, the upper lake being 13 miles in length with an area of 9278 acres, and the lower 24 miles in length with an area of 28,000 acres. Both lakes are dotted with numerous islets, and the lower one is famed for its picturesque beauty. Lough Corrib and Lough Mask have respectively an area of 43,484 and 22,219 acres. The country to the west of Lough Corrib contains about 130 lakes, 25 of which are more than a mile in length. The lakes of Killarney in Kerry, which are three in number and closely adjoin each other, are situated in the midst of wild and picturesque mountain scenery. The area of the lower lake is 5001 acres, of the middle one 680, and of the upper one 430. Lough Dearg, a small lake in the south of Donegal, has been resorted to from time immemorial as a place of penance by Roman Catholics. The other lake of the same name in the course of the Shannon has an area of 29,570 acres. The other principal lake districts are Sligo, Cavan, Westmeath, and Longford. Hull, in his *Geology of Ireland*, makes a classification of the lakes, according to their modes of formation, under the three heads of—(1) lakes of mechanical origin, (2) lakes of glacial origin, and (3) lakes of chemical solution. Of the first group, which are those whose formation is due chiefly to faults or dislocation of the strata, he mentions as special examples Lough Neagh and Lough Allen, both of which originated before the Glacial period, and probably between the Miocene and Pliocene periods. Those of glacial origin occur in the mountainous districts, and are due either to the scooping out of the rocks by the passage of ice over their surface, or to the accumulation of embankments at the end of the valleys or hollows. Those due to chemical solution are situated either on the limestone plain or in districts where the limestone formation has penetrated, and have been produced by the solution of the limestone through the action of water containing carbonic acid gas.

Coal.—Of the Upper Carboniferous beds which at one time overspread the central plain of Ireland, only small patches remain in isolated spots, serving chiefly as an indication of the immense loss that has been sustained in an important element of material prosperity. The principal coal-fields are the Leinster, the Munster, the Connaught, and the Tyrone.

The Leinster or Castlecomer field, situated between the Nore and Barrow, consists of a range of hills varying from 800 to 1000 feet high, and extending over portions of Kilkenny, Queen's county, and Carlow. It lies in the form of a basin, its most productive beds occupying the centre. These are the Middle Measures, but in the field both the Middle and Lower are represented. The coal is anthracite. The most common fossils are either terrestrial or freshwater, marine fossils being found chiefly in some of the upper beds. Above the Barrow coal in county Kilkenny several remarkable reptilian remains have been found. The Lower Measures consist of gannister beds resting upon Carlow flags, and contain some beds of shale and a few thin seams of coal, with several beds of marine fossils. This field is the most important in Ireland, and yields a larger weight of coal than all the others together.

The West Munster coal-field occupies portions of Clare, Limerick, Kerry, and Cork, and consists of a series of low hills extending from near Galway Bay in the north to Killarney in the south. All the three measures are represented, but there are only a very few workable seams, as most of the coal is very thin, and the strata very much inverted. The principal collieries are at Dunhallow in Cork, and the coal, which is anthracite, is used chiefly for lime-burning. Many of the Lower Measures are very rich both in terrestrial and in marine fossils.

The East Munster coal-field consists of a low range of hills in Tipperary, closely adjoining the Carboniferous hills in Leinster, from which they are separated by the river Nore. Thence it extends to near Cashel, a distance of about 20 miles, and its average breadth is about 5 miles. All the measures are represented. The productive portion of the field is at Killenaule, and consists of two thin seams in the Upper Measure. In the Lower Measures the principal fossils are marine; and plant impressions, especially those of ferns, are very numerous.

The Connaught coal-field embraces the mountainous district round Lough Allen, and includes portions of Sligo, Roscommon, and Leitrim in Connaught, and of Fermanagh and Cavan in Ulster. Both the Middle and Lower Measures are represented. They are composed chiefly of yellow sandstone and shale, and are overlaid by beds of grit. The coal is bituminous, and a large portion of it is workable.

The Tyrone coal-field includes the district between Dungannon and Lough Neagh, having a length of 6 and a breadth of 1 to 2 miles, and the small basin of Annaghone a little to the north. All the measures are represented. The coals have been worked only near the surface, but it is believed that very extensive and valuable seams of workable coal exist at lower depths.

The average quantity of coal raised in Ireland annually is about 130,000 tons, of which about 80,000 are raised in Leinster, 30,000 in Munster, 16,000 in Antrim and Tyrone, and 6000 in Leitrim and Roscommon. As the annual importation of coal exceeds 2,000,000 tons, it is evident that the coal supply obtained from Ireland's own mines is quite a minor element in its prosperity; but the industry might be much more largely developed, the total available amount of coal being estimated at 180,000,000 tons.

Peat.—For the absence of coal the country is to some extent compensated by the supply of peat fuel obtained from the red bogs situated in the central plain, and occupying a large tract included within two lines drawn across the island, the one from the Hill of Howth to Sligo, and the other from Wicklow to Galway. Originally this district was occupied by a forest, principally of oak trees, which after being gradually killed by the growth of mosses and other peat-producing plants, were succeeded by a forest of firs, these also in turn perishing. The average depth of the bog is 25 feet, but in some cases it is over 40 feet. According to its depth it varies in color, from whitish brown to a brown-black closely resembling coal. The brown or red turf in the centre forms the best fuel. The lower strata sometimes pass into lignite. Lignite of an immense thickness is found around the southern shores of Lough Neagh. In the mountain districts the bogs usually consist of brown turf of only about 12 inches thickness. Preglacial or interglacial peat has been found in Queen's county, county Galway, and county Tipperary, and submarine bogs with remains of an ancient pine forest have been discovered off the south-west coast. The bogs of the central plain contain in a state of good preservation animal and human skeletons, tree canoes, gold and silver coins and ornaments, crannogs or lake dwellings, log houses, and wooden roadways. The total area occupied by bog is 2,830,000 acres, or about one-seventh of the surface of the island, mountain bog occupying 1,254,000 acres, and flat red bog 1,576,000 acres.

Iron.—The deficiency in coal supply is the more to be regretted in the case of Ireland on account of its immense stores of iron, which for want of proper fuel remain unutilized. Red hematitic iron of a very rich kind is found associated with the coal-fields in the districts of Tyrone, and in Cork and Waterford. Valuable pisolitic ore occurs between the sheets of basalt in Antrim. Iron is met with in great quantities in the bogs, and is easily fusible, but the quality is not nearly so good as that of the clay iron which occurs in great abundance in the coal districts of Connaught. Some centuries ago the manufacture of iron was one of the most important industries of Ireland, the surface of the country being dotted over with small iron-works, in which the ore was smelted by wood charcoal; but as the supply of wood became exhausted the industry was wholly discontinued, the last of the old furnaces having been put out more than a hundred years ago. On the discovery of coal at the Arigna river near Lough Allen, iron-works were established there in 1788 which were carried on until 1808, and again revived in 1825, when the undertaking failed on account of the insufficiency of capital with which the company started. Of late years iron-mining has been prosecuted with some briskness in Antrim, as well as in Down and Londonderry. The quantity produced in the country has risen from 106 tons in 1860 to 77,600 tons in 1870 and 155,833 in 1879; but for the proper development of the industry the available supply of coke is wholly insufficient, and until other methods or materials of smelting have been discovered, the valuable iron ores of the country will contribute a very small modicum to its prosperity.

Gold.—From the gold ornaments and crucible ladles and other implements used in the purifying of gold that have been discovered in a bog on the borders of

Limerick and Tipperary, it would appear that that metal was manufactured there at a very early period; and there is a tradition that gold was smelted for King Tighearnmas about 1620 (or 915) B. C. in one of the valleys of the Liffey. About the end of last century a nugget of gold 22 oz. in weight was found in a tributary of the Ovoca, and, the Government having shortly afterwards taken up the enterprise, placer mining was carried on for some years. The gold was from 21⅜ to 21⅞ carats fine, the alloy being silver. The total value of the gold obtained at the Government works was £3675, while gold to the value of over £10,000 was obtained by private enterprise. All the gold has been found in shallow places. Very little gold is found in the iron or quartz veins, although pieces of iron are always found with the gold, and quartz is sometimes attached to the nuggets. The gold usually occurs in small grains, but nuggets of considerable weight are sometimes found.

Silver and Lead.—In very ancient times there were silver mines at Argetros, county Kilkenny, and near Toomavara, county Tipperary. The metal occurs both as native silver and in the lead ore, which sometimes yields as much as 80 oz. of silver to the ton. Lead is found in a greater number of localities than any other metal. Its most usual form is galenite, which occurs sometimes alone, but generally with sulphide of zinc, sometimes with the sulphides of iron and copper, and occasionally with sulphate of baryta and sulphate of strontium. In 1854 the lead mines of Ireland were wrought by ten companies, and the amount of ore raised was 3069 tons 15 cwts., yielding 2210 tons 15 cwts. lead and 18,096 oz. silver. Since that period the industry has gradually declined, until in 1875 it was prosecuted by only one company, that of Luganure in Wicklow; but since 1877 two mines have also been wrought at Carahan in Clare. Table II. gives returns from 1876 to 1879.

Copper.—The principal copper-mines are at Knockmahon in Waterford, at Cronebane and Connary in Wicklow, and at Bearhaven, Ballycommisk, and Cosheen in Cork. Chalcopyrite or yellow copper is the most common, but melaconite or black copper is found at Cronebane and Connary, and tetrahedrite or gray ore in the small beds to the south of Bearhaven. Native copper is common in most of the districts where the ore is found, and in many places large quantities of copper are collected from the streams by precipitation on iron. In 1854 the quantity of copper raised in Ireland was 12,171 tons, value £104,882. Since 1874 the industry has been on the decline, as may be seen from Table III.

Other Minerals.—There is a large lode of pyrites associated with the iron ore at Ovoca, county Wicklow, and native sulphur is found in the limestone in various districts as well as in some of the copper-mines. The produce of the sulphur-mines of Wicklow amounted in 1860 to 99,259 tons, in 1870 to 38,634 tons, and in 1879 to only 8262 tons. Tin stone has been found in a leaden lode at Dalkey, county Dublin, and also in the auriferous soil of Wicklow, but no lodes or workable deposits have been discovered. Salt is found at Carrickfergus and Larne in Antrim, and gypsum suitable for manure in the same districts. Molybdenite is found in a vein of granite near Roundstone in county Galway. Antimony, arsenic, sulphate of barytes, cobalt, magnesia, alum, and steatite all occur in several districts. Clays suitable for porcelain, as well as those used for coarse pottery, are not uncommon, and there are a great many quarries for building stone, flags, and slate, and also some for granite and marble. Lime is of course plentiful almost everywhere. Mineral springs, chiefly chalybeate, exist in the Upper Limestone in many parts of the country, the principal being Mallow in Cork, Ballynahinch in Down, Swanlinbar in Cavan, Castleconnel near Limerick, and Lucan near Dublin.

Climate.—The climate of Ireland is more equable than that of Great Britain, both as regards temperature and rainfall. No district in Ireland has a rainfall rising so high as that of large portions of the Highlands of Scotland, or falling so low as that of several large districts in the east of Great Britain. In January the mean temperature rises but little above 37° over the larger portion of the eastern slope of Great Britain, whereas in the same month it scarcely falls below 40° in any part of Ireland; and in July, whilst in Great Britain the extremes in the mean temperature are 64° in the London district and 54° in Shetland, the extremes in Ireland are 59° in the north and 62° in Kilkenny. Latitude accounts only for a part of these differences, which are mainly occasioned by the physical configuration of the surface in its relations to the prevailing moist W.S.W. winds. Ireland presents to these winds no unbroken mountain ridge running north and south, which would result in two climates as distinct as those of the east and the west of Ross-shire; but it presents instead only a series of isolated groups, with the result that it is only a few limited districts which enjoy climates approaching in dryness the climates of the whole of the eastern side of Great Britain.

Agriculture.—In wet years the excessive moisture is very prejudicial to cereal crops, especially in the southern and western parts of the island. Probably the returns either of corn or of green crops would in exceptional cases be very deficient under any mode of culture, and they might on the average, in the south-western district, be less remunerative than those of grass; but undoubtedly, if tillage were more practised on pasturage farms, the rearing and feeding of cattle would be more satisfactorily performed. Moreover, the soil in many cases is such that most kinds of crops thrive in the moist climate, and much might be done by drainage to procure a drier atmosphere and to mitigate the prejudicial influences of rainfall at the period of ripening. In regard to the natural fertility of the soil, and the ease with which it can be cultivated, Ireland as a whole has great advantages over Great Britain. Strong retentive clay soils, sandy soils, chalky and gravelly soils, are almost wholly absent, and the mixture of soils resulting from the great variety of stratification, as well as from the detritus carried down to the plains, has created many extensive districts of remarkable richness. The most fertile part of the country is the tract in Munster known as the "Golden Vein," stretching from Cashel in Tipperary to near Limerick. Along the banks of the Shannon there are long stretches of flat lands formed by deposits chiefly of calcareous and peaty matter carried down by floods, and at the estuary of the river this matter has been largely mixed with blue silt deposited by the sea. Extensive districts of similar formation are connected with the Suir, Nore, and Barrow, and with the Bann. In other parts of the limestone plain a rich soil has been formed by the decomposition of drift accumulated by the Esker Sea, mingled in some cases with the remains of granite; and a mixture of a variety of rocks has also greatly benefited many of the other limestone soils. The red bogs contain underneath them abundant marl admirably adapted for use in reclaiming the land. In many of the mountain districts the soil above the hard rocks consists of a thin stratum of vegetable matter. On the clay slate formations in Louth, Down, Wicklow, Wexford, Waterford, Cork, and Kerry, the soil is generally poor, except in the hollows, where rich patches have frequently been formed by rocky deposits. Similar remarks apply to the soils above mica slate. In the districts of the Old and New Red Sandstone, including the greater part of Cork, and portions of Kerry, Waterford, Tyrone, Fermanagh, Monaghan, Mayo, and Tipperary, the soil in the hollows is generally of remarkable fertility. Where gneiss and schist rocks prevail a finely productive soil frequently occurs, resting on inliers of limestone and other calcareous rocks. Indeed, Ireland contains comparatively little irreclaimable land, and even in the mountainous districts which are unsuitable for tillage there is often soil sufficient, with the aid of the moist climate, to yield pasturage of superior quality in great abundance; and more than two-thirds of the surface of the country, being less than 500 feet above sea-level, possesses a temperature well adapted to all the usual kinds of crop.

But, although enjoying such favorable natural conditions, Ireland as a whole lags far behind most other portions of the United Kingdom in agricultural progress, both as regards the circumstances of the peasantry and the development of the capabilities of the soil for producing food. The causes of this state of things are somewhat complex; and, having their chief connection either directly or indirectly with the procedure of the legislature, they have been in operation for several centuries, during which, instead of diminishing in influence, they have apparently gained strength by intermixing and entangling with each other. Until a comparatively recent period the system of landholding in Ireland was the tanistry or communal, governed by the ancient Brehon code. According to this code the land belonged primarily to the tribe or commune, and was vested in the chief or tanist, who, from his rank as a noble, held a portion of it as his own property, had a life interest in a second portion from the office to which he had been elected, and possessed jurisdiction over a third portion, the commonal land, which was divided annually. The nobles from among whom the tanist was chosen had a right of ownership of land, and another class had the right of ownership of chattels, which went to their sons by gavelkind. Only certain classes of the tribe—the Saer Céili or "free tenants," and Daer Céili or "base tenants"—could obtain security of tenure for life, the others being either yearly tenants, free laborers, or slaves. The interests even of the yearly tenant were preserved by stringent regulations, and in the course of generations it was possible to rise from the lowest social grade to the rank of a "free tenant." The lands of the tenants went to their male descendants by gavelkind. Even the free laborers and the slaves, with the exception of those who were convicts or prisoners, had the right of sustenance and shelter on the estate of their lord. Unlike those of Great Britain, the ancient laws of Ireland remained uninfluenced by Roman legislation; and, although the Danish invasions caused some disturbance of the old order of things, the regulations so far as the possession and tenure of land were concerned remained practically unmodified until the invasion of Henry II. The natural consequence was that the pastoral mode of life associated from the beginning with the Brehon code should also remain unchanged, the more especially as soil and climate alike were favorable to the growth of luxuriant pasturage; but, as pastoral employment is that which is least able to support a dense population, a large proportion of the servant class gradually sank into a condition of idleness and wretched poverty. Unhappily the result of the Anglo-Norman invasion was not to improve this state of things by the gradual influence of other laws and customs, but to introduce into the social system disturbing and irritating elements, which kept alive all the old evils in a more aggravated form. Henry II. nominally bestowed the entire land of Ireland upon ten of his followers, but practically, with the exception of the small district of the Pale, it remained in the possession of its ancient lords. Confiscations became more frequent as the power of the English increased, and within that portion of the territory over which English rule did not extend, the tenants and laborers, in the unsettled condition of society, suffered severely from the irresponsible authority of the nobles. Henry VIII., the first English sovereign who really held sway over the whole island, induced the nobles to acknowledge him on condition that their ancient rights and privileges were left intact; but this arrangement was set aside by Elizabeth, whose reign was signalized by the great wars resulting in the composition of Connaught and the planting of Munster. By the former of these, while possession was secured to the nobles in their estates, the lands in the province were alienated from the clan to the chief, and the free tenants became virtually proprietors of their farms; and by the latter 574,628 acres, the estate of the earl of Desmond, were parcelled out to be peopled according to a plan founded wholly on English customs. Soon after the accession of James I. in 1603, tanistry and gavelkind were abolished by decision of Queen's Bench, and the estates of the Ulster nobles—511,465 acres in extent—were forfeited to the crown, to make way for the great plantation of Ulster. The custom of gavelkind was, however, revived by the Act of Queen Anne against the Catholics, and the statute was not repealed till the reign of George III. The confiscations were repeated on a larger scale during the Stuart and Cromwellian periods, from which time may be dated the complete practical overthrow of the Brehon system except in Ulster and a few isolated districts, where the shadow of it still lingers in the custom known as tenant-right. Even, however, after the subjugation of Ireland by Cromwell, Sir William Petty, in his *Political Anatomy*, written in 1672, estimated the value of the tenant's claims for improvements and benefit of leases at one-third of his annual rental. The same writer calculated that, whereas in 1641 about two-thirds of the good land belonged to the Irish or Catholics, at the time he was writing the proportion was as nearly as possible reversed, the figures being as follows:—Purchased by the Protestants of Connaught of the transplanters 80,000 acres, possessed by the English and Protestants and Church 5,140,000, possessed by the Irish 2,280,000. Of the 1,100,000 inhabitants, the proportion of Irish to English was as 9 to 3; and 6 out of every 8 of the Irish lived in a "brutish nasty condition." After the confiscations which followed the wars of William III., the Catholics did not possess more than one-seventh of the soil. The penal laws by which the Catholics were disabled from holding freehold property tended to effect a still further transference of proprietorship to the Protestants. The functions of the proprietor were generally performed by the large Protestant tenant, to whom a long lease of the property was granted, and who sublet to the Irish farmer. Frequently the farms were subdivided and sublet to the third, fourth, or fifth degree, and, as the Catholics were disabled from holding leases for more than thirty-one years, and at less than two-thirds of a rack-rent, they necessarily occupied the lowest step in this peculiar social scale. Instead of an industrious and thriving class of peasant proprietors, which the Brehon system left to itself would in all probability have gradually developed, a race of wretched cottiers sprang up, whose only inheritance now guaranteed to them by the remains of the old Brehon system was their deep-seated conviction as to their inalienable rights to the soil; the custom which, without now recognizing these rights, threw upon them the expense not only of fencing, draining, and other improvements, but of the erection of all the dwellings on the farm; and their dependence on the proprietor, one, however, who was now generally an alien, and from whom they held their small patches of soil on payment in labor according to conditions strung to the utmost degree of severity by the process of subletting and an unlimited competition. Support by any other form of industry than agriculture was rendered impossible by laws which practically paralyzed the commerce and manufactures of the country, and agriculture itself was additionally hampered by the enactments passed in the reign of Charles II. against the exportation to England of cattle, sheep, and pigs, of salt beef and bacon, and even of butter and cheese. These enactments, combined with that final one by which the prohibition formerly passed against the exportation of woollen manufactures to England or the colonies was extended also to foreign countries, caused the "middle men" to turn their attention to woollen smuggling; and, finding it a more lucrative means of livelihood than that of squeezing money from impoverished tenants, they in many instances drove the cottiers from their farms, which they changed into sheep walks.

The Acts of 1771, 1778, and 1782, which removed the Roman Catholic disabilities in regard to the holding of leases and property, and the Act of 1793, which extended to the Catholics the forty shillings franchise, had, on account of the peculiar social condition created by former legislation, practically as disastrous effects as even the penal laws which they superseded. The landlords for election purposes created an immense number of the lowest kind of freeholds, which they let at exorbitant rents owing to the high price of provisions during the great war. These prices indeed gave a temporary stimulus to agriculture, and led to the conversion of a considerable amount of pasturage into tillage, but practically the position of the freeholder was more servile than that of the previous tenant-at-will, and when prices sank to their normal rate at the close of the war he found himself in a condition of absolute ruin. At the same time, by this minute subdivision of leaseholds, an immense increase had taken place in the agricultural population, whose numbers could perhaps scarcely have found support under any system of agriculture, although undoubtedly under a system of peasant proprietorship support would have been possible to a much larger number, inasmuch as the principal profits of tillage would have fallen into the hands of the tillers of the soil instead of those of absentee proprietors. To aid the landlords in freeing themselves from the incubus of impoverished tenants an eviction Act was passed in 1816, and further protection was afforded them by the Subletting Act of 1826, but it was not until after the abolition of the forty shilling leasehold suffrage in 1829 that any important diminution took place in the leaseholds. Under tenancy-at-will, which was then generally substituted, the subdivision of holdings was not materially diminished, although for some years previous to the occurrence of the potato blight and the repeal of the Corn Laws more than one-fourth of the population stood in need generally of relief, and the landlord, in order to escape the burdensome taxation consequent upon the Poor Law Act of 1838, had begun the transformation of small holdings into large farms. Table IV., compiled from special parliamentary returns giving the number of freeholds by counties, will illustrate the influence of various acts of legislation on the growth of freeholds, and especially their rapid increase after 1793 and their rapid decline after 1829.

The potato blight and the repeal of the Corn Laws, occurring nearly simultaneously, caused an immediate and almost complete sweep to be made of the smaller class of holdings. The consequence was an enormously rapid diminution of the population, which made whole districts of the county almost tenantless, but which, great as it was, only removed the abnormal strain of hardship under which the peasant was suffering, and brought him no permanent relief from his burdens by an increase of wages or more favorable terms of occupancy. Indeed, tenancy-at-will was still further increased by the Parliamentary Votes Act of 1850, which granted the suffrage to those who for twelve months were rated as occupiers of land valued at £12 a year.

The change which has taken place in the size of the holdings since 1841 is sufficiently indicated in Tables V., VI., and VII.

The number of holdings of less than one acre is not given in the census returns of 1841, but the number of persons occupying the holdings is given in Kennedy's *Digest of the Evidence of the Devon Commission*. Reckoning that no one possessed more than one holding, the total diminution in the number of holdings between 1841 and 1880 would thus be 252,294, or, not including holdings under 1 acre, 167,593. The number of occupiers in 1880 was 527,444, or 46.778 fewer than the number of holdings. The diminution in holdings took place chiefly between 1841 and 1851, that is, practically between 1846 and 1851, this decline being 218,450. It was confined to farms not exceeding 15 acres in extent, which between these years declined as much as 380,884, and between 1851 and 1880 have declined by only 41,425. Those not exceeding 1 acre, principally the potato gardens of the cottiers, between 1841 and 1851 declined by 97,586, or nearly three-fourths; since 1851 they have increased by more than one-fourth. Farms above 1 and not exceeding 5 acres declined between 1841 and 1851 by 222,353, or nearly three-fourths; and those above 5 and not exceeding 15 acres by 60,945, or nearly one-fourth. Between 1851 and 1880 the decline in farms of the former class has been 23,791 and of the latter class 30,519, there having been a slight increase in this class in the province of Connaught. The largest increase in the number of holdings took place in those exceeding 30 acres, the additions between 1841 and 1851 being 100,465, and between 1851 and 1880 only amounting to

12,374, the greatest proportional increase between 1841 and 1880 being in the provinces of Connaught and Ulster. The increase between 1841 and 1851 in farms above 15 and not exceeding 30 acres was 61,969, and between 1851 and 1880 there has been a decrease of 4793, there having been a slight increase in Connaught. In farms above 30 acres in extent, the increase between 1851 and 1880 has been greatest, both in numbers and in proportion, in those above 50 and not exceeding 100 acres. Since 1861 the decrease in the total number of holdings has been gradual but continuous; and the slight increase between 1851 and 1861 is more than accounted for by an increase in the gardens of the cottiers. The largest proportional decrease in the number of holdings, 8 per cent. above that for Ireland, has been in Munster, where, as will be seen from subsequent statistics, the increase of the acreage under pasture has also been greatest.

The relation which the decrease in the number of holdings has had to the decrease in tillage may be to some extent understood from Table VIII., which gives the percentages of acreage in the various classes of holdings for 1854, 1861, and 1871, with the percentage of land in each class under crops, grass, fallow, woods, and bog or waste respectively. The registrar-general's returns do not supply materials for such a table for 1851. It will be seen that there is an uninterrupted decline in the proportion of land under crops according to the increase in the size of the holdings, it being over 80 per cent. in those less than 1 acre, over 60 per cent. in those above 1 and not exceeding 5 acres, and only a little over 3 per cent. in those above 500 acres. On the other hand, the acreage under grass is in farms between 1 and 5 acres only about 28 per cent., and reaches its maximum, nearly 60 per cent., in farms above 200 and under 500 acres; and, while the extent of bog and waste is scarcely 8 per cent. in farms between 1 and 5 acres, it gradually increases with the increase in the size of the farm until it is over 60 per cent. in those above 500 acres. The acreage under crops remained nearly stationary between 1854 and 1871 in all the classes of farms, but the acreage under grass increased 2·5 per cent., the increase being wholly in farms of above 30 acres, while there was a decrease of about 1 per cent. in the case of all classes of farms below 15 acres in extent. The increase may almost be accounted for by reclamations, the decline in the acreage under bog and waste being between the same periods about 2·4 per cent., which occurs principally in farms above 50 acres in extent, there being a considerable increase in the case of some of the other classes of farms. The nature of the change in regard to cropping and tillage which has taken place since 1847 is shown more distinctly in Table IX., which gives the acreage under the different kinds of crop in 1847, 1851, 1861, 1871, 1879, and 1880. Table X. gives the acreage under crops, grass, fallow, woods, and waste for 1851 and 1880, and Table XI. shows in detail the proportions per cent.

The general result of Table IX. is to show a total decline between 1847 and 1880 in the area under crops amounting to 157,351 acres, the decrease having taken place after 1861, up to which year there was from 1847 an increase of 651,961, the decline between 1861 and 1880 being 809,312, or more than one-seventh. The stated area under crop in 1847 conveys, however, a misleading impression, as the area under potatoes was only 284,116 acres, whereas in 1846 it was estimated at 1,237,441, the difference being undoubtedly due to the fact that in 1847 a great portion of this area was left out of cultivation. Thus, if 1846 had been substituted for 1847 it would have been found that in the area under crops there was a decrease between 1846 and 1851 probably as great as that which occurred between 1851 and 1880. This latter decrease amounted to 777,727 acres or 3·8 per cent. of the area of the country, the decrease in Leinster being 383,143 or 7·6 per cent., in Munster 268,351 or 4·5 per cent., in Ulster 107,750 or 2 per cent., and in Connaught 18,623 or ·4 per cent. Unfortunately the commissioners' reports do not give the acreage in 1847 under grass, and the census returns of 1841, though they give the acreage of arable land, do not distinguish between that under grass and that under crop. If, however, we deduct the amount under crop in 1847 from the total arable area in 1841, which is stated at 13,464,000 acres, we have only 8,225,425 acres under grass, the increase of grass land between 1841 and 1851 being, according to this calculation, 523,152 acres, while if we add the acreage left out of crop in 1847 it is probably 1,000,000 acres more. Since 1851 the acreage under grass has been gradually but uninterruptedly increasing, the increase between that year and 1880 being 1,510,531 acres or 7·5 per cent. of the whole country, there being thus in all probability about 2,500,000 more acres under grass in 1880 than in 1841. In Leinster the increase has been 470,842 acres or 9·7 per cent., in Munster 572,746 or 9·6 per cent., in Ulster 98,422 or 1·7 per cent., and in Connaught 368,521 or 8·8 per cent. The largest percentage under grass is in Munster, and the smallest in Ulster, the proportionate difference between the two being 14·5 per cent. But in addition to this stated increase of acreage under grass, it is to be remembered that a large proportion of the acreage under meadow and clover comes properly under this category, being really untilled land, and that this has increased between 1847 and 1880 by 770,961 acres, the increase in Leinster being 146,227, in Munster 253,866, in Ulster 211,334, and in Connaught 159,534. Thus if we deduct the area under meadow, the decrease in the area under crops between 1847 and 1880 would, even according to this table, be 928,312 acres, there being a decrease in cereals of 1,547,145, and an apparent in-

crease in the area of green crops of 519,611 acres, and in flax of 99,222. As, however, about 1,000,000 acres formerly under potatoes were in 1847 left out of cultivation, it is probable that between 1846 and 1880 there was a decrease in the acreage under green crops as large as the apparent increase between 1847 and 1851. If, on the other hand, the acreage under meadow and clover be added to that under grass, the increase between 1851 and 1880 of the two combined is 2,175,552 acres, and between 1841 and 1880 it is probably nearly 3,500,000.

Sir William Petty estimated the area of Ireland in 1641 at 10,500,000 Irish acres, or 17,008,264 English acres, of which he classed 1,500,000 Irish acres, or 2,429,752 English acres, as rivers, highways, bogs; an area of similar extent as very coarse land; and 7,500,000 Irish acres, or 12,148,760 English acres, as good meadow, arable, and pasture. According to the returns of the Census Commissioners of 1841, the area of arable land comprehended 13,464,000 acres, plantations 374,482, water 630,825, and uncultivated land 6,295,735. Between 1841 and 1851, owing to works undertaken both by Government and private proprietors in order to give relief at the period of famine, the area of arable land showed the large increase of 1,338,581 acres, there being a decrease in the extent of waste land amounting to 1,086,493 acres, and in the area under woods amounting to 69,476, while the area under waste includes a large acreage under water. The returns of 1841 are, however, much less accurate than those from 1847. Between 1851 and 1880 the arable lands increased from 14,802,581 to 15,355,598 acres, or by 553,017, there being a decrease in the waste land of 577,184 acres, and an increase of the area under woods of 34,952 acres, while the total acreage of the country is stated in somewhat larger figures. The percentage of decline in waste land for the whole acreage of the country was 2·9, there being a decline of ·6 in Leinster, and of 4·5 in Munster, an increase, strange to say, of ·7 in Ulster, and a decline of 7·8 in Connaught, where there is still the large percentage of 33·2. Of the 4,632,308 acres returned for Ireland under the head of waste land in 1880, 1,718,386 acres were returned as bog and marsh, viz., 325,864 in Leinster, 324,826 in Munster, 372,387 in Ulster, and 695,309 in Connaught; and 2,064,361 acres as barren mountain land, 157,618 being in Leinster, 699,732 in Munster, 679,285 in Ulster, and 527,726 in Connaught. According to the report of Sir Richard Griffith, the total number of acres improvable in 1844 was 3,755,000, of which 1,425,000 were improvable for cultivation and 2,330,000 for pasturage. The reclamations of waste between 1841 and 1851 nearly all took place after 1844, and the total acreage of reclamations between 1841 and 1880 is 1,663,427, leaving therefore an acreage in 1880 of waste but reclaimable land amounting to 2,091,573. The term waste land is, however, used in a rather vague sense, and might without much exaggeration be made to include a considerable portion of the area now classed as arable. The significance of the change which has taken place in the acreage of the principal crops will be better understood if the tables already given are compared with Tables XII. and XIII.

The area under cereals has declined between 1847 and 1880 by 1,547,145 acres, or nearly one-half; while in 1847 the produce of cereals reached 2,548,723 tons, in 1878 it amounted to only 1,226,655 tons, and in 1880 to 1,275,678 tons, the difference between 1847 and 1878 amounting to 1,322,068, and between 1847 and 1880 to 1,273,045. Allowance must, however, be made for the fact that since 1855 the estimates of produce, having been corrected by the Poor Law Guar-

dians, have generally been lowered; and, of course, the weather introduces a very variable element. In any case it would appear that generally there has been a decline in productive power from 1856 until 1871. For the five years up to and including 1860 there is a much lower average than for the five previous years, and the decline still continues for the ten years up to and including 1870; but, except in the case of potatoes and cabbage, there is an increase for the ten years following, due to the high averages of 1874 and the two subsequent years. The decline in the productive power may doubtless in a considerable degree be accounted for by the fact that the increase in the acreage under pasturage took place chiefly in the richer districts of the country, but it is also attributable, as is the low average still attained, to inadequate manuring, insufficient draining, inattention to the destruction of weeds, over-cropping, or in a word, to general ignorance in regard to the proper methods of culture. In some isolated instances the system of agriculture practised is quite on a par with that on the best farms of England and Scotland, and within recent years considerable progress has been made; but as a whole an approach to a satisfactory state of things exists only in Ulster, where agriculture has the stimulus both of tenant-right and of manufactures. In Ulster the average produce per acre is now equal to the average of Ireland, although in 1642 it was rated to the "adventurers" as worth only 4s. an acre, while land in Leinster was rated at 12s., in Munster at 9s., and in Connaught at 6s. The southern and western districts of the country lag farthest behind, and generally proximity to Great Britain seems to exercise an advantageous influence. Griffith's valuation, apart from other objections, of course supplies no test as to the agricultural value of the land at the present time, and has the disadvantage that the southern and western districts were valued immediately after the famine. By it the total annual value of Ireland was given as £11,439,575, that of Ulster being £2,533,265, of Munster £3,247,177, of Leinster £4,305,413, and Connaught £1,353,720.

An increase in the average produce of wheat per acre might naturally be expected from the fact that its area is now restricted to those districts where soil and climate are specially suitable. The decline in the area under wheat between 1847 and 1880 has been 595,235 acres, or more than four-fifths. It has been specially large in Leinster and Munster, but the fact that it has also been considerable in Ulster and Connaught shows that it must be attributed to other causes besides a real or supposed unsuitability of climate. In 1878 the amount of wheat produce was less by 499,191 tons than in 1847, and in 1880 it was less by 503,190 tons. The decrease in the acreage under oats has not been proportionally so great; but, inasmuch as oats are the staple crop of the country, it is perhaps even more significant. Between 1847 and 1880 the decrease in area was 818,927 acres; and the decline in amount of produce in 1878 as compared with 1847 was 705,689 tons, and in 1880 it was 634,998 tons. The decrease in the acreage under cereals has by some been accounted for by an increase in that under potatoes, but although between 1851 and 1861 this increased by 265,003 acres, it has since gradually diminished, being 47,773 less in 1880 than in 1851. The increased productiveness of the potato in 1880 is attributed both to the favorable season and the importation of new varieties, especially the "Champions." The report of the special potato inquiry of 1880 shows that "Champions" were grown on 220,934 acres, "White Rocks" on 194,778, "Skerry Blues" on 116,959, and "Scotch Downs" on 98,342. Between 1851 and 1880 there has been a diminution in the total area under green crops of 125,247 acres. It is certainly remarkable that, while the number of cattle has so largely increased, not only the area but until recent years the average produce per acre of turnips and mangolds, the staple winter food of cattle, has been diminishing. The aggregate produce of turnips was less by 1,395,100 tons in 1878 than in 1851, in 1879 by 4,023,522 tons, and in 1880 by 1,741,638.

The nature of the increase which has taken place in live stock since 1841 is brought out in Tables XIV.–XVII.

TABLE XIV.—*Number of the various kinds of Live Stock in Ireland and its four Provinces for 1841, 1851, 1861, 1871, and 1880.*

(The figures for 1880 in Tables XIV. and XV. are taken from the Agricultural Abstract, and differ slightly from those in the complete return.)

The returns for 1851 give no information as to the number of horses used for agricultural purposes, but Table XV. supplies this information for 1861, 1871, 1879, and 1880. Table XVI. gives the total value of each kind of live stock for 1841, 1851, and 1871 on holdings above one acre, and the average value of the same on each holding, the valuation given agreeing with the rate originally fixed by the commissioners, according to which horses were estimated at £8 each, asses at £1, cattle £6, 10s., sheep £1, 2s., pigs £1, 5s., goats 7s., and poultry 6d. The value of all classes of live stock has of course greatly increased within recent years, but although a table representing the actual increase of value in live stock would throw an important light on certain aspects of Irish agriculture, these considerations cannot be entered into here, and as the increase is due almost entirely to other causes than increased merits in the live stock, a table at a fixed rate more exactly represents the change in value so far as it depends upon the agriculturist.

As horses and mules are classed together in the returns of 1841, no comparison can be made as to the difference in the number of horses between that year and 1880; besides, the returns of 1841 are much more inaccurate than those since 1847. Between 1851 and 1880 horses increased by 35,447, but between 1861 and 1880 they decreased by 57,079, agricultural horses diminishing by 66,853, undoubtedly an indication of a diminution in tillage, but not a criterion as to its amount, both because the horses are not fully occupied, especially on small farms, and because a considerable amount of farm work is done by bullocks, which are much better suited for this work than the small and weak horses kept on most farms. Asses have more than doubled in numbers since 1841, and have increased between 1851 and 1880 by 49,264, a sign both of poverty and of lazy and inefficient work.

Cattle have increased between 1841 and 1880 by 2,080,471, or have more than doubled in numbers, and between 1851 and 1880 by 953,565, or scarcely so much as between 1841 and 1851. The only pure native breed of cattle now in Ireland is the "Kerry," a light handsome animal, black or red in color, with upturned horns. It is easily kept, and in quality both its flesh and its milk resemble those of the finer West Highlands. The variety known as the "Dexter," a cross between the "Kerry" and some unknown breed, is shorter and plumper than the pure "Kerry," and has none of its finer points; and in Connaught there is another breed of cattle which is also a coarse variety of the "Kerry." In some parts of the country the Scotch West Highland breed has been introduced. The "old Irish" breed which existed in the central parts of the country has now been all but eradicated by crossing. The English Longhorn was at first the animal principally used to improve the breed of the Irish cattle, but it was ultimately supplanted by the Shorthorn, and the greater number of Irish cattle are now crosses with that breed. Polled Scotch cattle have also been largely introduced into the mountain districts, and in Ulster and Cork the Ayrshire or a cross between it and the Shorthorn is the breed chiefly used for dairy purposes. Milch cows in 1880 exceeded a third of the total number of cattle,—the numbers of the three classes of other cattle (those under one year, those above one and under two years, and those above two years) being pretty nearly equal. The proportion of milch cows to the total number of cattle in Leinster was less than one-fourth, in Munster nearly one-half, in Ulster above nine-twentieths, and in Connaught about three-eighths. Since 1861 the number of milch cows has decreased by 148,335, the decrease having nearly all taken place since 1871. Dairy farming is carried on chiefly in the south, more especially in Cork, where the methods practised are generally greatly superior to those of the other districts. In Cork the cows are generally wintered partly on turnips or cabbage, and to some extent also on artificial feeding stuffs, but in other districts they are often not housed even in winter, and what they gather from the winter pastures is supplemented only by an allowance of hay. The milk is used chiefly in the manufacture of butter, the buttermilk being employed for feeding pigs, and forming also along with potatoes or stirabout an important element of family

diet. On account of the bad household arrangements of the small farms, the butter manufactured is often dirty and unwholesome; and it is also frequently oversalted. Cheese is not manufactured except by some of the Scotch or English farmers for their own use. The proportion of calves kept may be gathered from the number of cattle under one year old, which in 1880 was less than the number of cows by 555,813. On the best farms the cow calves are generally kept. Only a very small number of calves are fattened for the butcher, but many are killed when only a few days old. Those that are kept scarcely ever receive warm milk after the first week, but are fed chiefly on buttermilk, hay-tea, and similar substitutes. This early process of half starvation, joined to imperfect winter housing and feeding, leaves effects on the constitution of the animals which greatly lessen their value for the butcher; and, although the breed of cattle in Ireland is one which fattens quickly on good pasturage, the animals, besides being smaller than they would otherwise have been, are always deficient in "tallow," and generally weigh about 2 stones less than those of apparently similar dimensions reared in England or Scotland. Scientific cattle-feeding is only practised in exceptional cases.

Sheep have increased between 1851 and 1880 by 1,439,233, there having been very little increase between 1841 and 1851. The number is smallest in Ulster, which possesses only about one-eighth of the whole. The old native breed has been greatly improved by the introduction of Leicesters, and within recent years Border Leicesters have been largely introduced, as well as Shropshire Downs. In the mountain western districts there are large flocks of Cheviots and Scotch Blackfaced. The sheep possessed by the small farmer are generally of a very mongrel character.

Pigs between 1841 and 1851 decreased by 268,244, but between 1851 and 1861 increased by 17,185, and between 1861 and 1871 by 519,381, while between 1871 and 1880 they declined by 772,377. They constitute a very important item in the economy of the small farmer, and their carcases are largely sold to supply the English market. The old Irish "grey-hound" pigs, which were very nearly allied in race to the wild boar, are now almost extinct, their place having been taken chiefly by Berkshires, although Yorkshire and Cumberland breeds are not uncommon.

Table XVIII. shows the progress of the cattle export trade to the United Kingdom since 1790.

Between 1841 and 1851 poultry diminished by 863,733, much less than might have been expected from the decrease in small farms; and between 1851 and 1880 their numbers have nearly doubled, the larger portion of the small farmers' returns being now often obtained from the rearing of geese and turkeys and the produce of eggs. The breed of domestic fowls is somewhat mixed, but Dorking and Spanish fowls are becoming more common.

An approximation to a proper estimate of the deficiencies of the chief branch of Irish agriculture, the rearing of cattle, may be obtained by a computation founded on a comparison of its statistics with those of Great Britain. In 1880 the average number of cattle to every 100 acres under cultivation was 25·5, the average of England being 16·9, of Wales 23·7, of Scotland 23·2, and of Great Britain 18·4. Horses in the same year had an average in Ireland of 3·3, that of England being 4·4, of Wales 4·9, of Scotland 4·1, and of Great Britain 4·4. The average of sheep was for Ireland only 23·2, while for England it was 68·4, for Wales 98·2, for Scotland 149·3 and for Great Britain 82·9. Of pigs the average in Ireland was 5·5, in England 6·9, in Wales 6·6, in Scotland 2·6, and in Great Britain 6·2. While in Great Britain, with a permanent pasturage of 14,426,959 acres, the number of cattle amounted to 5,912,046, in Ireland, with a permanent pasturage of 10,259,108 acres, they amounted to 3,921,026, the number of cattle in England to every 100 acres under grass being 41·0, while in Ireland it was 38·2. But in addition to this the pasturage of Great Britain supported 26,619,050 sheep, while that of Ireland supported only 3,561,361, or rather fewer sheep than cattle, and less than one-seventh of the number of sheep supported in Great Britain; and if we regard six sheep as equal to one of the cattle, which is less than the estimated value, the number of cattle supported on every 100 acres in Great Britain would be 71·7, the number in Ireland being only 44·6. It would certainly not be exaggeration to estimate the cattle of Great Britain as on an average one-fourth better than those of Ireland, and if this be so, it follows that compared with Ireland at least double the value of cattle and sheep are supported on the same amount of pasturage in Great Britain. (Thom's *Almanac* gives the value of cattle, sheep, and pigs of Ireland in 1880 as £60,904,429, and those of Great Britain as £138,559,045, reckoning those of each country as individually of equal value.) In Great Britain, however, the combined area under rotation grasses and under green crops, excluding potatoes, is 7,360,060 acres, as against only 2,326,538 in Ireland, the area devoted chiefly to the rearing of cattle and sheep being in Great Britain 21,787,019 acres, while in Ireland it is only 12,585,646, the average, reckoning six sheep as equal to one of the cattle, being thus 47·5 animals to every 100 acres devoted to rearing them in Great Britain as against 35·9 in Ireland; or, reckoning the animals in England as one-fourth better, the proportions are 59·3 to 35·9.

If, moreover, it be remembered that in Ireland pasturage occupies nearly all the richer districts of the country, and that where tillage is carried on the first principles of scientific agriculture are generally unknown, we cannot be underestimating the food produce of Ireland in stating it as about two-fifths less for the acreage than that of Great Britain; and since 1847 there has, owing to the increase of pasturage, been a great decline in the production of food. From the inadequacy of the information given by the Board of Trade it cannot be determined with accuracy to what extent Ireland is dependent on other countries for supplies of corn and meal. From special parliamentary returns we learn that the total foreign imports of grain in 1850 were 1,683,687 qrs., and of meal and flour 220,107 cwts., and that the exports to Great Britain from Ireland exceeded the imports from it in the case of grain by 242,287 qrs., and of flour by 708,008 cwts. In 1855 the exports of corn and meal to Great Britain exceeded the imports from Great Britain and foreign countries together by 451,627 qrs. In the yearly returns of imports of foreign corn and meal into the United Kingdom no separate column is given for Ireland; and, in addition to this, since 1867 no return has been given of the trade in corn and meal between Ireland and Great Britain. Weekly returns of the imports of foreign grain into Ireland are, however, published in the *London Gazette*, and Table XIX., founded on a special parliamentary return and on the *Gazette* returns, gives the total amount of foreign imports of grain and meal in 1865, and in each year from 1870.

Notwithstanding that much of the land now under pasturage is well adapted for turnips or mangolds, the amount of green crop grown is generally quite insufficient for scientific cattle-rearing. In many cases also the grass is laid down after the soil has been exhausted by over-cropping, and little pains generally are taken to improve the soil by draining or manures. The increase in pastoral farming has indeed been largely due to the desire to save trouble, one of the principal difficulties of the large farmer being to obtain, notwithstanding a low general average of wages, the worth of his expenditure in hired labor. The indolent habits of the peasantry, due to long ill fortune, constitute also a principal obstacle to the introduction of spade culture, which has been advocated as well suited for the climate and soil of Ireland, and as affording employment to the largest possible agricultural population. As it is, the small farmer, living in a wretched hovel which he shares with a considerable portion of his live stock, is able, on account of the fewness and simplicity of his wants, to succeed, though making use of very primitive methods of culture, where the larger farmer wholly dependent on hired labor would fail if he attempted a system of tillage even according to the most approved methods.

For the promotion of the agricultural progress of the country grants of various kinds are bestowed by Government. Since 1847 an act for granting land improvement loans has been in operation, and since the passing of the act up to the 31st March, 1881, the total number of loans issued has been 7328, amounting to £3,278,762,—the applications for the year 1880–81 being 638, amounting to £161,575. The quantity of land drained since the commencement in 1847 until the 31st March, 1881, has been 274,827 acres, at an average cost of £7 per acre. The number of loans for farm buildings sanctioned since the passing of the act 13 & 14 Vict., c. 31, until the 31st March, 1881, has been 1528, amounting to £771,360,—the number of loans sanctioned during the year ending 31st March, 1881, being 133, amounting to £53,670. Under 23 Vict., c. 19, the number of loans sanctioned for dwellings for agricultural laborers has been 462, amounting to £263,465,—the cases for the year up to 31st March, 1881, being 16, amounting to £11,155. The whole expenditure charged against the different undertakings commenced under the Arterial Drainage Acts (prior to 1863), including £70,201 for rent chargeable to counties, amounted at the close of the operations to £2,390,612, 12s. 4d., of which £2,249,540 was advanced on loan, and £141,073 by way of free grant, and the repayments in respect thereof, including interest, amounted on 31st of March, 1881, to £1,413,944. The loans sanctioned since the passing of the Acts in 1863 amount to £553,295. The advances on account thereof, including interest charged during the operations of the works, amount to £411,116, and repayments, including interest, to £103,448. The total area of land drained and improved is 55,311 acres, at a cost of £325,705. In view of the prevalent agricultural distress, the Government on 29th November, 1879, offered to landlords within the radius of distressed districts certain facilities of obtaining loans under the Lands Improvement Acts, and on 12th January, 1880, offered additional inducements. Of the sum of £1,500,000 borrowed from the Church Temporalities Commissioners for relief works, £1,166,385 had up to March, 1881, been sanctioned as loans to landlords, and of this sum £702,857 had been issued. The amount issued as Seeds Loans, under the Seed Supply Act of 1880, was for year ending 31st March, 1881, £494,317, making a total of £647,490 since the passing of the Act.

One of the chief obstacles to agricultural improvement in Ireland has been the unsatisfactory relations between landlord and tenant. The legislation bearing on the subject has been of a very various and contradictory character. An immense number of holdings was created by the Freehold Votes Act of 1793; but in 1816 an Act was passed to facilitate the working of the Ejectment Act first passed in the reign of Queen Anne. In 1851 an Act was passed to facilitate ejectments in cases of implied tenancies from year to year under £50 rental, and in 1860 these facilities were increased and extended to all tenancies. There are no records of evictions earlier than 1849. A special return presented to the House of Commons in April, 1881, gives by provinces and counties the number of evictions for each year from 1849 to 1880, as ascertained by the police. The numbers are of course only approximately correct, but err by defect, not by excess. The total number of families evicted during that period was 90,107, comprising 460,570 persons; but of these, 21,340 families, comprising 115,859 persons, were readmitted. Deducting readmissions, the numbers in 1849 were 13,384 families, 72,065 persons; in 1850 they were 14,546 families, 74,171 persons; in 1851 they declined to 8815 families, 43,449 persons; and they gradually diminished until 1856, from which year until 1862 the numbers though fluctuating fell short in each year of 1000 families. There was a considerable diminution from 1865 till 1878, when they rose to 834 families, or 3916 persons, while in 1879 the numbers were 1098 families, or 5576 persons, and in 1880 they were 1893, or 9036 persons. During the half year ending 30th June, 1881, the numbers evicted were 1433 families or 6557 persons. In 1865 it was enacted that no evictions should take place without the intervention of the sheriff; but, although a means was thus supplied of obtaining records absolutely correct, the sheriffs in some instances neglected to send in returns. In Table XX. the figures for 1870–79 are taken from the judicial statistics, and those for 1880 from a special return. These ejectments do not include those of cottiers and weekly tenants in towns whose cases are decided by petty sessions. The large increase of ejectments since 1870 shows that the Landlord and Tenant Act of that year has failed in ordinary circumstances to improve the relations between landlord and tenant; and, while some of its provisions have had in certain respects a beneficial effect, it has also exercised a variety of prejudicial influences, and not only broke completely down under the strain of the famine of 1879, but in many cases led to the almost unavoidable infliction of great hardship on the tenant. The salient principle of the Act was the abandonment of the position assumed in the Act of 1860, which endeavored to place the relation of landlord and tenant on the simple basis of contract. Stated positively, its leading features were the legal confirmation of the Ulster tenant-right and other ancient customs, the provision made for compensation for loss on quitting and for improvements, and the sanctioning of grants on loan and other facilities to tenants to aid in the purchase of their holdings. Since the passing of the Act the average sum adjudged annually in cases between landlord and tenant has been over £18,000, of which more than a third has been for Ulster tenant-right. The amount adjudged annually has varied considerably but irregularly, and of late years there has been a diminution in

TABLE XX.—*Ejectment Decrees executed from 1870–80.*

the number of cases. The judicial statistics give information, in reference to the several counties and provinces, as to the number of cases, the amount charged where decrees were made, the amount reduced or added on appeal, and the amount adjudged, distinguishing also between compensation for loss on quitting holdings and improvements together, for loss on quitting holdings alone, and for improvements alone. In 1877 and 1878 an additional column was added, giving also the total sum claimed. The sum claimed in 1877 was £225,225 for the 598 cases, an average of £425, the gross sum adjudged being only £15,401, or an average of £25, 10s.; in 1878 the sum claimed was £176,954, an average of £344 for the 514 cases, the gross sum adjudged being £17,063, or an average of £33; in 1879 the gross sum adjudged was £12,654. The total number of loans made to aid tenants in purchasing their holdings up to 31st March, 1881, was only 849, and the gross sum granted £492,370. Table XXI. gives various details. According to a special return made to the House of Commons in April, 1881, the number of holdings sold by the Church Temporalities Commission up to 30th December, 1880, was 2444 to the public, and 6195 to tenants. Of the 411 purchasers who had fallen in arrears, 332 were purchasing tenants, arrears £4619, and 79 other purchasers, arrears £3813.

To remedy the defects of the Act of 1870, a new Act was passed in 1881. Practically it secures to the tenant a near approximation to the "three F's"—"free sale," "fair rent," and "fixity of tenure." "Free sale" is granted so far as is compatible with a due regard to the rights of the proprietor. The "fairness" of a rent may be decided by the "intervention of court," and, while on certain conditions a "fixed tenancy" may be agreed upon between landlord and tenant, an approximation to this is obtained in other cases by provisions in regard to rent and "compensation." Additional facilities have also been given to tenants to purchase their holdings, and provision has been made for grants of money to aid in the reclamation of land and in emigration. A feature of the Act is the creation of a land commission as a supreme court of appeal, except in special cases, in questions between landlord and tenant, and with the power of sanctioning loans.

Leases are not held by so many as one-tenth of the total number of farmers, tenancy-at-will being preferred, partly for the freedom it allows, and partly because it is thought to involve a tacit consent to permanent occupancy.

One of the chief hindrances to agricultural progress in Ireland has been absenteeism. According to Sir William Petty, who wrote in 1672, one-fourth of the real and personal property of Ireland was possessed by absentees. Prior, in his *List of Absentees*, published in 1729, divides them into three classes—those who are seldom or never seen in Ireland, those who visit Ireland for a month or two, and those who are occasionally absent. The money spent out of Ireland by the first class he estimated at £204,200, by the second at £91,800, and by the third at £54,000. According to another account, published in 1769, the income of the first class is placed at £371,900, of the second at £117,800, and of the third at £92,000. Arthur Young gives the rental of absentees in his time as £732,200, about one-seventh of the whole estimated rental, and Swift declared that one-third of the rental of Ireland was spent in England. Absenteeism continued to increase until the close of the great war in 1816, and although it diminished from that time, a substitute for many of its evils was supplied by the rapid impoverishment of a large number of idle and extravagant squireens. To help in freeing the country from this incubus, an Act was passed in 1848 to facilitate the sale of encumbered estates in Ireland, which however proved wholly ineffectual, and was superseded by another in the following year appointing a commission of three persons to constitute a court for the purpose. This court commenced its sittings in October, 1849, and from that period until it closed its sittings in August, 1859, 3547 sales were effected, the gross amount of which was £25,190,839. In 1859 the court was reconstituted on a permanent footing under the title of the "Landed Estates Court," power being conferred on it to deal with unencumbered as well as encumbered estates. Up to January, 1880, the sales in this court amounted to £27,277,140, so that probably about one-sixth of the whole area has changed hands through the action of the two courts. The average price for the five years ending 1867 was 17½ years' purchase; in 1870, the year of the passing of the Land Act, it fell to 16½ years' purchase, but in 1873 it had risen to 20 years' purchase. and for the six years ending 1877 it was 19·4, while for 1878 it was 18·9, and for 1879 only 17·7. The action of the Encumbered Estates Court was of a somewhat arbitrary kind, and in the beginning of its operations it forced the sale of estates at a time when their market value was much below the average. In addition to this it introduced a large number of proprietors who looked at their purchase entirely from a business point of view, and who, though quite alive to the importance of agricultural progress, had little regard for the feelings of their tenants; having bought the improvements which the tenant had effected, they naturally had no scruples in raising the rents so as to make them represent the value of these. It is not probable that the land sales have

Corrected statement, 1878....	25,727	4,812,412	4,560,342	15,780	5,898,370	3,311,085	21,982	5,260,269	4,125,945	5,266	4,190,999	1,422,650	68,755	20,162,050	13,420,022

increased very much the number of proprietors; for, although they caused a subdivision of many large estates, a number of small estates have been consolidated, and in many cases more than one estate has been purchased by the same person. On the whole, however, the result has been to increase the estates of a medium size, and also probably to lessen the number of absentees. From a return presented to the House of Commons in 1872, it would appear that the number of proprietors resident on their estates in 1870 was 5589, possessing 8,880,549 acres, with an annual value of £4,718,497, while there were 4842 proprietors resident either usually or constantly elsewhere in Ireland, who possessed 5,215,264 acres, with an annual value of £2,499,343; 2973 rarely or not usually or never resident in Ireland, who possessed 5,129,169 acres, with an annual value of £2,470,816; and 5982 unclassed, who possessed each less than 100 acres, and together 236,872 acres, with an annual value of £257,100. 25·5 per cent. of the soil is thus owned by absentee proprietors, and 26 per cent. by proprietors who, though resident in Ireland, are not resident on their properties.

According to the classified summary return of owners of land in Ireland laid before the House of Commons in 1876, the land in 1873 was divided among 68,716 proprietors, who together possessed 20,157,557 acres, with a ratable annual value of £13,418,357, or, according to the corrected statement of 1878, 68,755 proprietors, possessing 20,162,050 acres, with a ratable value of £13,420,022. Table XXII. gives a classification of proprietors according to the area of their estates, and their numbers in the several provinces and in all Ireland, with the acreage possessed by each class collectively, and its ratable valuation,—the result of the corrected statement of 1878 being also added.

According to the returns presented to the House of Commons in 1872, which have the advantage of omitting cities and towns, the total number of rural proprietors in 1870 was only 19,547, possessing a total area of 20,046,182 acres, with a ratable value of £10,180,434. A return obtained by the Irish Government in 1870, and ordered by the House of Commons to be printed in 1876, gives the number of rural proprietors as 19,288. It also shows that only 2377 possessed less than 25 acres, so that nearly all the proprietors of less than 1 acre must be in towns. The classified returns of 1876 show that nearly one-half of the whole acreage of the country is possessed by 749 proprietors holding each upwards of 5000 acres, and that more than four-fifths of the land is possessed by 3750 proprietors holding upwards of 1000 acres. Compared with Great Britain, the number of proprietors is strikingly small, Scotland having twice as many, and England nearly fourteen times as many. The proportion of landowners possessing less than 1 acre is very much smaller, and that of those possessing less than 500 acres is also smaller. Further details of comparison with England and Scotland will be found in the article ENGLAND, vol. viii. p. 202–204.

Woollen Manufacture.—Though Ireland is without the stimulus to industry produced by an abundant supply of coal, yet with its great command of water power it might have widely developed its manufactures before the introduction of steam, had not special causes been in operation to check their progress. The unsatisfactory political and social relations of the country, and the unhappy legislation which had blighted its agriculture, would necessarily in any case have indirectly stunted its manufactures also; but, in addition to this, they were specially discouraged by various restrictive and repressive Acts. For a considerable period after the Anglo-Norman invasion Ireland was, however, in this respect placed on an entire equality with England, and in Acts passed in the reigns of Edward I., Edward III., and Edward IV. is specially exempted from the duties or prohibitions imposed on foreign manufactures.

At an early period the woollen manufactures of Ireland were exported in considerable quantities to foreign countries. In a posthumous poem, *Dita Mundi* (two copies of which are in the British Museum, of dates 1474 and 1501), by Bonifazio Uberti, who died about 1367, mention is made of "the noble serge" which Ireland sent to Italy; and Irish frieze is specially excepted by name in an English statute of 1376. Five mantles made of Irish frieze are mentioned in a list of goods exported duty free from England to Pope Urban VI. Considerable impulse was given to the manufacture in the reign of James I. by the establishment of a colony from the Palatinate, in Germany, at Carrick-on Suir, but in the reign of Charles I. the clothing trade was discouraged by the earl of Strafford, lord-deputy, who to prevent it interfering with that of England endeavored to foster the linen manufacture instead. The Act of the 12th of Charles II., which prohibited the export of raw wool both from Ireland and England to foreign countries, was in the case of Ireland not only harmless but ineffectual; but, in addition to this, Ireland was virtually debarred from the English market by the heavy duties imposed on her woollen manufactures, and, being left out in the Navigation Act of 1663, she was also debarred from the colonial market. The foreign market was, however, left open to her; and after the prohibition of the export of Irish cattle to England the Irish farmer was led to turn his attention to the breeding of sheep, when not only did the woollen manufacture increase with great rapidity, but, owing to the superiority of the wool, the materials manufactured were of such a quality as to awaken the alarm of the English manufacturer, at whose instance both Houses of Parliament petitioned William III. to come to the rescue. In accordance with his wishes, the Irish parliament in 1698 imposed additional heavy duties on all woollen clothing with the exception of friezes exported out of Ireland, and in the following year an Act was passed by the British Government prohibiting the export from Ireland of all woollen goods to any country save England, to any port in England save six, and from any town in Ireland save six. Sir William Petty in 1641 estimated the number of woollen workers and their wives at 30,000, but the result of these Acts was so disastrous as practically to annihilate the manufacture, to reduce large districts and towns to the last verge of poverty, and seriously to cripple the revenues of the kingdom. Notwithstanding, however, that Ireland ceased to make even for her home supply any but the coarser articles, and was forced to import her finer goods from England, the Acts were almost as injurious to the English as to the Irish manufacturer; for not only did many of the skilled Irish workmen settle in France, Spain, and the Netherlands, but by means of smuggled Irish wool, to the extent of four-fifths of the Irish fleeces annually, the foreign manufacturer was able at a much smaller cost to fabricate materials quite equal to those of England, and for a time almost to swallow up her Turkey wool trade. According to the tables given by Newenham, the annual average of new drapery exported from Ireland for three years ending 25th March, 1702, was only twenty pieces, and that of old drapery 4 yards, while the export of woollen yarn, worsted yarn, and wool, which to England was free, amounted to 349,410 stones. The annual average export for the three years ending 1722 had risen to 5494 yards for new drapery and 364 yards for old drapery, while that of yarn, worsted, and wool, owing doubtless to smuggling, had fallen to 188,450 stones, and for the three years ending in March, 1732, fell as low as 96,953 stones, but for the three years ending in 1772 had risen to 129,191 stones, of which wool amounted only to 2247 stones. The returns as to the exports of new and old draperies from 1722 to 1777 are incomplete. Arthur Dobbs, in his *Essay on the Trade of Ireland*, published in 1729, estimated the medium exports of wool, worsted, and woollen yarn at 227,049 stones, which he valued at £117,554, 15s. 10d.,—the other exports of manufactures made from sheep, such as friezes, flannel, gloves, etc., being estimated at £2353, 5s. On the other hand the annual average of new drapery imported for three years ending in 1702 was 29,329 yards, and of old drapery 15,787 yards; and the averages gradually rose till they were 84,631 yards and 18,726 respectively for the three years ending in 1722; 379,766 and 206,875 for the three years ending in 1772; and, according to Arthur Young, 485,609 and 259,466 for the seven years ending in 1777. Between 1779 and 1782 the various Acts which had hampered the woollen trade of Ireland were repealed or greatly modified; but, although a temporary impulse was thus given to the manufacture, the imprudent manner in which it was prosecuted and the influence of the remaining statutes led in the majority of cases to disappointment, and after a short period of deceptive prosperity, followed by failure and distress, the expansion of the trade was limited to the supply of the home market. Thus, while the annual average of new drapery exported for the three years ending in 1792 had risen to 352,309 yards and of old drapery to 10,688 yards, the averages fell for the three years ending in January, 1802, to 18,028 and 2007 respectively; while the average imports of new drapery for three years rose from 379,989 in 1782 to 1,077,471 in 1802, and of old drapery from 251,251 to 1,474,000. In 1823 the imports of new draperies into Ireland had risen since 1801 from 967,225 yards, valued at £120,903 in Irish currency, to 1,437,652 yards, valued at £179,706; while the import of old draperies had risen from 911,082 yards, valued in Irish currency at £637,757, to 1,188,366 yards, valued at £831,856. Since 1825, owing to the cessation of duties, returns of the exports and imports of Ireland to and from Great Britain have ceased to be issued. According to the evidence laid before the House of Commons in 1822, one-third of the quantity of woollen cloth used in Ireland was imported from England, the value being about one-half. The number of persons employed in the manufacture was 6500, while worsted stuffs and flannels employed each about 3000 more, in addition to which probably other 35,000 were dependent on these workers for their livelihood. According to a return presented to parliament in 1837, the number of woollen or worsted factories in Ireland was 46, all situated in Dublin or in the southern counties of Ireland, the number of workers employed being 1321; and in a special return relating to factories for 1839 the number of woollen mills is stated as 31, employing 5 steam engines with a horse-power of 58, and 39 water-wheels with a horse-power of 523, the number of workers being 1231. Table XXIII. gives the number of factories, spindles, power-looms, and persons employed in the woollen and worsted manufacture at various periods from 1850. In addition to this, a large number of persons are employed in handloom weaving,—farming in many cases also occupying part of their time.

Linen Manufacture.—The linen manufacture of Ireland has suffered fron legislation chiefly indirectly—from the trade restrictions which hampered the commerce of the country generally, and from the depressing influence of an unsatisfactory social system and unfavorable agricultural relations. At a very early period flax was to some extent cultivated in Ireland, and was both spun into thread, which was exported to foreign countries, and manufactured into cloth, which was made use of for cloaks, for the headdresses of women, and for shrouds. But although the manufacture was so well known in the beginning of the 15th century as to be noticed in an English poem of that period, and is mentioned in a statute of Henry VIII. as constituting along with that of wool one of the principal branches of the trade of Ireland, there is no probability that it would have rivalled that of wool unless it had been artificially fostered and the latter artificially all but annihilated. The earl of Strafford, lord-deputy in the reign of Charles I., with a view both to discourage the woollen manufacture of Ireland and to obtain for England a cheaper supply of linen than was to be had from France or Holland, as well as probably to benefit himself, invested as much as £30,000 of his fortune in the promotion of the linen trade, and not only imported flax-seed in large quantities from Holland, but offered premiums to induce skilled workmen from France and the Netherlands to settle in Ireland. A similar policy was vigorously prosecuted by his successor the duke of Ormond, who in 1665 procured the passing of an Act by the Irish parliament to encourage the growth of flax and the manufacture of linen. In addition to this he despatched persons to the Netherlands to obtain a knowledge of the best mode of manufacture, and he brought over a number of families from Brabant and others from France and Jersey whom he settled at Carrick and at Chapelizod near Dublin, in both which places he established flourishing factories. Following the same line of policy, an act was passed by the English parliament inviting foreign workmen to settle in Ireland, and admitting all articles made of flax or hemp into England duty free, a privilege which, according to the report of the Irish House of Commons in 1774, gave Ireland an advantage over foreign nations of 25 per cent. In 1698 the Irish parliament, in answer to the representations of England, promised that they would "heartily endeavor to establish a linen and hempen manufacture," but this promise was at first only fulfilled by levying prohibitory duties on the exports of woollens, and the linen trade in 1701 had made such comparatively small progress that the value of the exports of cloth was only £14,112, and of the exports of linen thread £39,106, 18s. 4d. In 1705 the Irish were, however, permitted to export their white and brown linens to the British colonies, but not their striped and dyed linens, which were also excluded from England by a prohibitory duty of 30 per cent. In 1710, in accordance with an arrangement entered into between the two kingdoms, a board of trustees was appointed to whom a considerable sum was granted annually for the promotion of the manufacture; but the jealousy of England nevertheless

interposed to check the manufacture whenever it threatened to interfere with her own trade, and by an Act of the 23d of George II., which imposed a tax on Irish sailcloth imported into England, the hempen manufacture was virtually annihilated. From 1700 to 1777 the sum expended by the Board of Trustees on the promotion of the linen trade, according to tables given by Arthur Young, amounted to £847,504, the annual average amount for the fifteen years up to 1772 being £14.100. In addition to this bounties were granted for the import of flax-seed, which during seven years up to 1777 averaged £15,094 annually; and a special parliamentary bounty was also paid annually, which in 1777 amounted to £4000, and from 1700 to that date to £192,540. At first the total sum applied to the encouragement of the trade was very small, being in 1700 only £100, and in 1703 £430: but the grants increased rapidly from 1716, and altogether between 1700 and 1777 they amounted to £1,295,560, the total annual average grant for the seven years ending 1777 being £33,540. The linen manufacture of England was, however, also encouraged by bounties, which according to the statistics of M. César Moreau amounted in 1824 to £73,392, those of Ireland amounting only to £17,528. Table XXIV., compiled from statistics supplied by Arthur Young and M. Moreau, shows the increase of the linen manufacture so far as this can be judged from a comparison of the exports of linen cloth and yarn to all parts of the world at various periods from 1710 to 1823. Arthur Dobbs estimated that in 1727 the value of the whole linen manufacture, including both that exported and that used for home consumption, was about £1,000,000 sterling.

The Linen Board ceased to act in 1830, the trade having since 1825 been in a very depressed condition owing to the importation of English and Scotch yarns made by machinery, which undersold the home-made article. A flax-spinning factory had indeed been erected at Cork in 1805, but appears to have been unsuccessful, and no further attempt to introduce machinery seems to have been made until after the discontinuance of the Linen Board, when an experiment on a large scale was made on the Bann near Belfast, from which period may be dated the rise of the great linen trade of Ulster, where, with the gradual disappearance of the hand spinning in the other provinces, nearly the whole linen manufacture of Ireland became concentrated. Statistics as to the acreage and produce of flax will be found under "Agriculture," *supra*. It is in the province of Ulster that flax is chiefly grown, but the soil has in many instances been much deteriorated by a too frequent rotation of the crop. The flax of Irish production in 1880 was estimated at 24,508 tons, of British production at 1398, while the foreign imports of flax into the United Kingdom amounted to 94,812 tons. The cessation of the duties on exports from Ireland to Great Britain deprives us of the means of tracing the progress of the modern development of the linen industry. It was calculated that in 1855 the total exports of linen from Ireland to Great Britain and foreign countries was 106,000,000 yards, valued at £4,400,000, and undoubtedly since that period it has more than doubled. According to the report of the Flax Supply Association of Belfast for 1876, it was estimated that in 1875 the consumption of fibre in all the mills of Ireland was about 45,897 tons, or about one-seventh of that consumed by all the flax mills in existence. It was also estimated that the total quantity of yarns produced per annum was 21,373,700 bundles, of which 10,479,040 were supposed to be manufactured into cloth by power-looms, and 5,850,000 by hand-looms, in addition to which about 2,000,000 bundles were supposed to be imported from Great Britain and the Continent, leaving for export 7,044,660 bundles,—fully two-thirds of the production and imports into Ireland of yarn being converted into linen fabrics in Ireland. According to the report made to parliament in 1837, the number of workers employed in the flax factories of Ireland was 7810, and according to the returns relating to factories for 1839 the number of mills engaged in the manufacture was 40, employing 32 steam engines with a horse-power of 928, and 37 water-wheels with a horse-power of 1052, the total number of persons employed being 9017. Table XXV. gives returns at various periods from 1850. In the report of the Flax Supply Association for 1881 the number of spindles is estimated in 1881 at 927,295 and of power-looms at 21,177.

In 1880 there were 1182 scutching mills, a decrease of 317 as compared with 1871. The number of persons employed in the jute and hemp factories is over 1000.

Cotton Manufacture.—The cotton manufacture was introduced into Ireland in 1777, and a mill for spinning twist with water-power was erected in 1784. Under the protection of high import duties and bounties the manufacture increased with such rapidity that in 1800 it gave employment to 13,500 workers, chiefly in the neighborhood of Belfast. At the Union it was arranged that the duties, which then stood at 68 per cent. *ad valorem*, should remain unchanged for eight years, when they were gradually lowered by eight annual reductions, until in 1816 they stood at 8 per cent., and were shortly afterwards abolished. According to the statistics given by M. César Moreau, the manufacture between 1804 and 1820 had more than doubled, the cotton, cotton yarn, and twist imported into Ireland for the three years ending in 1804 amounting to 2,244.582 ℔, whereas for the three years ending in 1820 it was 4,787,071 ℔. The value of cotton goods exported from Ireland to Great Britain rose from £708 in 1814 to £347,606 in 1823, and between 1814 and 1826 the value of those exported to other parts of the world rose from £37,569 to £201,196. According to a statement made to the House of Commons in 1817, the number of hands employed in the manufacture was 12,091; and in 1822 they had increased to 17,756. It is evident that the introduction of machinery had prejudicial effects on this industry as well as on the linen trade, for, according to the returns relating to factories for 1839, the number of cotton mills is given as 24, employing 19 steam engines with a horse-power of 517, and 22 water-wheels with a horse-power of 572, the number of persons engaged being only 4622. The manufacture of course suffered greatly during the famine of 1846, and in 1850 the number of factories was only 11, employing 2937 persons. In 1861 the number had declined to 9, employing 2734 persons, and, although in 1870 it had risen to 14, employing 4157 persons, the check experienced during the American war has never been surmounted, the number of factories in 1874 being only 8, employing 3075 persons, and in 1879 declining to 6, employing 1620 persons.

For some time a large manufacture of lace and sewed muslin has been carried on in Ulster and some parts of Munster and Connaught—the sewed muslin trade being much the more extensive of the two. More than 300,000 persons, chiefly females, are employed in it, many of them being girls in the convent schools. Of late the trade has, however, been declining.

Silk Manufacture.—This was introduced into Ire-

land about the end of the 17th century by French Huguenots, who after the revocation of the edict of Nantes settled in Dublin, where great perfection was attained in the fabrication of a mixture of silk and wool called tabinet or Irish poplin. According to Lord Sheffield, who wrote in 1785, 1500 persons were employed in the manufacture. M. Moreau gives the quantity of raw silk imported into Ireland in 1803 as 27,384 ℔, and that of thrown silk as 59,441 ℔, while in 1823 the quantities were 27,869 and 21,195 respectively. He also inferred that in 1823 between 3000 and 4000 persons were employed in the manufacture. In 1825 a company was formed in the south of Ireland for the purpose of obtaining a supply of the raw material by rearing the silk-worm, but after considerable expense had been incurred the scheme was abandoned as impracticable. With the abolition of the protective duties in 1826 the manufacture gradually declined. In 1874 the number of factories was only 2, employing 400 persons, and in 1879 was represented by 1 factory, which employed 152 persons.

Miscellaneous Manufactures.—There is 1 hosiery factory employing 119 persons, and 2 hair factories employing 38 persons. There is a considerable paper manufacture, which since the repeal of the paper duties in 1860 has been increasing. For most other articles in common use, such as glass, hardware, soap, candles, and many clothing materials, Ireland is nearly altogether dependent on England.

Distillation.—For several centuries Ireland has rivalled Scotland in the manufacture of whisky, the spirit of each country having its own special excellences. Camden states that in Ireland usquebagh was much used to stop the fluxes and catarrhs caused by the excessive moisture of the climate, and that the Irish spirit was much "less heating and more drying" than that of England. An excise duty was first imposed on the manufacture in 1661, the rate charged being 4d. per gallon. This was raised in 1715 to 7d., and in 1717 to 8d. In 1719, when a new method of reckoning by the size and number of stills was introduced, the revenue realized was £5785, 9s. 4d. In 1791 the amount produced by a rate of 1s. 2d. was £204,648. Various alterations were subsequently made in the methods of reckoning, and a system of survey was also combined with the old method, but the few capitalists who judged it advantageous to engage in the trade succeeded in baffling all the efforts of the Government to stop the issue of spirits which had not paid duty. The amount of spirits produced by distillation avowedly illicit vastly exceeded that produced by the licensed distilleries. According to Wakefield, stills were erected even in the kitchens of baronets and in the stables of clergymen. More commonly they were placed in retired districts on loose stones, so as to be easily removable on the approach of the revenue officers. In 1685 the number of stills seized was 2974, of heads 2656, and of worms 2378. The duty was gradually raised till it stood at 4s., and, after being reduced in 1811 to 2s. 6d., it was raised in 1814 to 5s. 6d. This addition to the duties added very little to the revenue, while of course it greatly increased the temptations to illicit manufacture. According to M. Moreau, it was the opinion of competent judges that in 1822 the amount produced by the licensed and unlicensed stills was not less than 10,000,000 gallons, while the amount brought to charge in the same year was only 2,950,647. For the six years ending 1818 the number of stills seized was 7233, of heads 5291, and of worms 5109, and for the six years ending 1826 the numbers were 13,017, 9475, and 8014 respectively, the number of prosecutions being nearly 18,000. Since that period illicit distillation has been largely practised up till the present time, the number of cases in 1880 being 685. Table XXVI. gives the amount of Irish spirits brought to charge in various years from 1821.

Breweries.—There are breweries in most of the large towns of Ireland, and Dublin is celebrated for its porter. In 1880 the number of common breweries was 53, and of licensed victuallers 16,686, the malt consumed by the former being 3,965,887 and by the latter 1864 bushels.

Fisheries.—An account of the fisheries of Ireland will be found under the headings FISHERIES, vol. ix. p. 211 *sq.*, and SALMON FISHERIES. The salmon fisheries employ between 11,000 and 12,000 persons. The deep sea and coast fisheries now employ only about 6000 boats and 20,000 persons, whereas the numbers in 1860 were 13,483 and 55,630 respectively. A reproductive loan fund for fishery purposes was constituted by the 12th section of the Act 37 & 38 Vict. c. 86, and the loans advanced up to 31st December, 1880, amounted to £31,079, of which £20,675 has been repaid. The average annual produce of the oyster fisheries is about £50,000.

Commerce and Shipping.—So far as natural advantages for commerce and shipping are concerned, Ireland is scarcely rivalled by any other country. Her coast is not only surrounded by safe anchorages, but the land is so deeply indented by bays and inlets, and so intersected by a network of internal navigation, that no part is more than 24 miles from water communication with the sea. In regard also to situation, it is difficult if not impossible to fix on a country whose circumstances are more favorable. Lying contiguous to the coast of Great Britain, and at some points almost touching it, she is nearer than that country to the West Indies, the continent of America, the west coast of France, the coasts of Spain and Portugal, and the ports of the Mediterranean. There is abundant evidence to show that Ireland was prepared to make use of these advantages, and that only impolitic trade restrictions have prevented her from developing a commerce which would undoubtedly have vied with that of Great Britain, but from which Great Britain would have gained more than she was in dread of losing. These restrictions, however, imposed when the great manufacturing industries of modern times were in their early infancy, not only snatched from her the possibility of commercial greatness, but, operating along with other legislation, doomed her to agricultural stagnation and centuries of poverty and distress; so that in fact contiguity to Great Britain has proved to be to her a bane rather than a blessing, and America, instead of affording her the means of enrichment, has only supplied her with an asylum for her poverty-stricken sons.

From allusions in Strabo, Ptolemy, the northern sagas, Richard of Cirencester, and other old writings, it would appear that Ireland early in the present era had considerable commercial intercourse with various parts of Europe. At the time of the Anglo-Norman invasion, the merchants of Dublin having fled from the city, it was given by Henry II. to merchants from Bristol, to whom free trade with other portions of the kingdom was granted, as well as other commercial advantages. During the reigns of the Edwards, Irish ships were frequently employed in supplying the English armies with provisions, and in the Staple Act of Edward III. Dublin, Waterford, Cork, and Drogheda are mentioned as among the towns where staple goods

could be purchased by foreign merchants. The trade of these and other towns had increased in the 15th century with considerable rapidity, and Sir John Davies, writing in 1612, speaks in commendation of the encouragement then given by the government to the commerce of the maritime towns and cities. The first restriction on the trade of Ireland was an Act passed in 1637 imposing duties on the chief commodities to foreign nations not in league with England. Though included in the Navigation Act of 1660, she was, however, left out in that of 1663, and in the same year was prohibited from exporting her cattle to England in any month previous to July. Gerard Boate, writing in 1652, gives a description of the various havens of Ireland. Sir William Petty estimated that between 1657 and 1672 her foreign trade had doubled, and that before the statute of 1663 "three-fourths of the Ireland foreign trade was with England, but now not one-fourth part of the same." The value of exports he computes at £500,000 per annum. About the time he was writing, the inhibition against exports to Great Britain was extended to include both dead meat and also butter and cheese. A trade was, however, carried on at this time with France, Spain, and Italy, not only in cattle and agricultural produce, but in salmon and herrings as well as various kinds of manufacture; but Arthur Dobbs was of opinion that from the Restoration until 1688 the exports of Ireland never exceeded £600,000 per annum. In 1681 the exports amounted to £582,814, and the imports to £433,040. On account of previous wars the exports in 1695 amounted to only £295,592, the imports exceeding them by £95,932; but owing chiefly to the prosperity of the woollen trade they had risen in 1698 to £996,305, the imports amounting to £576,863. Upon the prohibition of the exports of woollen manufactures to foreign countries, a rapid fall took place in the exports, which, although the value of those to Great Britain remained much the same, did not reach to the amount of 1698 until 1714, the recovery being due in part to the gradual increase of the linen manufacture, the value of whose exports rose between 1700 and 1714 from £14,112 to £313,329. Table XXVII., compiled from statistics given by Newenham, Arthur Young, and M. César Moreau, gives the annual value for 1698, and the average annual value for various periods from 1701 to 1823 of Irish exports and imports from and to all parts of the world, and from and to Great Britain.

1814–1823	6,963,451	5,675,673	6,626,409	4,921,879

A better idea of the commercial progress of the country would have been obtained if space had been available for tables of the different articles of export and import, for, besides giving more detailed information, it would have afforded a more accurate basis for an estimate, since Table XXVII. is so far vitiated by being given in Irish currency, which was altered at various periods, and by the fact that the method of rating at the custom house has also varied. On the latter account it was reported to the House of Commons in 1811 that the augmentation of trade during the 18th century appeared from such valuations to be greater than it really was. The increase has, however, been considerable, for we find that between 1710 and 1777 the quantity of linen exported had risen from 1,688,574 to 19,714,638 yards, while the export of oats, wheat, and barley had been nearly quadrupled, and there was also a large increase in the exports of live cattle, and of beef, butter, and pork. The table shows a large increase, especially in the value of exports, after the peace in 1748, and while there is a diminution shortly before the passing of the Acts granting free trade, there is a rapid revival after that period; and there are also very evident signs of the prosperity Ireland was experiencing during the wars with France. Since the cessation of the shipping duties on the cross channel trade in 1825, there are no data for obtaining accurate details regarding the trade with Great Britain; and, in addition to this, the Board of Trade has ceased since 1870 to give returns of the foreign and colonial trade for each of the separate kingdoms of England, Scotland, and Ireland. Returns are given, however, for the principal ports of each kingdom. Table XXVIII. gives the value of the foreign and colonial trade of Ireland at various periods down to 1870, and of its principal ports for 1875 and 1879.

Another means of estimating the commercial progress of Ireland during this period is supplied by the returns of shipping. Prior in his *Observations on the Trade of Ireland* gives an estimate of the tonnage of the shipping engaged in the trade of Ireland from 1721 to 1727, according to which the number of ships in the former year was 3499 with a burthen of 158,422 tons, while Arthur Dobbs gives their number for the same year as 3334 with a tonnage of 158,414, and their number in 1714 as 3081 with a tonnage of 161,115. The tonnage of the ships belonging to the ports of Ireland in 1727 is given by Prior as 40,469, the total number of ships trading with Ireland being 3494, with a tonnage of 173,193. According to the statistics of M. Moreau the number of Irish ships in 1788 was 1016, the tonnage being 60,776, or a third more than in 1727; and in 1826 they had increased to 1391, with a tonnage of 90,768. Table XXIX. gives the number and tonnage of vessels registered in the ports of Ireland in 1840, 1850, 1860, 1870, and 1880.

According to the statistics of M. Moreau, the number of ships that entered the ports of Ireland in 1795 was 7086, with a tonnage of 630,506, and in 1801 they had increased to 7690, with a tonnage of 711,242. Returns of the trade and navigation of Ireland have since the Union been annually presented to parliament. Table XXX. gives the number of British and Irish and foreign vessels engaged in the foreign and colonial trade that entered and cleared at the ports of Ireland at various periods from 1802; Table XXXI. the number of ships that entered and cleared coastways in various years during the same period; and Table XXXII. the number of ships engaged in intercourse between

Great Britain and Ireland that entered and cleared British and Irish ports at various periods from 1835, the figures in this table of course representing about double the number of ships actually engaged in the trade.

Details as to the several articles of foreign trade will be found in the Board of Trade returns of the principal ports; but without information as to the trade with Great Britain it is impossible to estimate their significance. The returns of the foreign trade are unsatisfactory, inasmuch as they show a great excess of imports over exports. The principal export trade to foreign countries is in linen, spirits, and malt liquors; while the imports embrace large quantities of wheat, wheaten flour, Indian corn, and oatmeal. On the other hand the country is dependent chiefly on Great Britain and foreign countries for its manufactured goods. Much of its trade is, however, an indication rather of poverty than prosperity, for it is the absence of manufactures that causes such large imports of textile fabrics, and the large exports of cattle, dead meat, and butter, which would otherwise be consumed by her town population, while at the same time the large imports of corn and wheat into a country chiefly rural, are undoubtedly due to wrong or insufficiently advanced methods of agriculture.

Shipbuilding.—About nine-tenths of the total shipping of Irish construction is built in Belfast, and the whole amount is very small. Next to Belfast come Dundalk, Dublin, Cork, Drogheda, and Galway,—much in the order named. The number of vessels built in Ireland in 1850 was 25 of 1929 tons burthen; in 1860, 42 of 11,582 tons; in 1875, 16 sailing vessels of 18,655 tons, and 5 steam vessels of 3613 tons. In 1880 they numbered respectively 3 of 1873 tons, and 10 with 7131 tons burthen.

Revenue and Expenditure.—Until the time of Henry VIII. the English rule in Ireland was only nominal, except within a very small district; and, while statistics as to the revenue would thus be of little advantage for comparison with later times, they are not obtainable except in a very fragmentary manner. Henry VIII. levied a subsidy of 13s. 4d. on every ploughland; and, besides reviving the tax upon absentees first enacted by Richard II., he also obtained a considerable sum from the suppression of several of the monasteries. During the first fifteen years of the reign of Elizabeth the expenses of Ireland, on account chiefly of the wars, amounted, according to Sir James Ware, to £490,779, 1s. 6d., while the revenue is estimated by some writers at £8000 per annum and by others at only £6000. In the reign of James I. the customs gradually increased from £50 to £9700; but, although he obtained from wardships and other feudal rights about £10,000 per annum, and a considerable sum also accrued from the plantation of Ulster, the revenue is supposed to have fallen short of the expenditure by about £16,000 per annum, the cost of maintaining the troops in Ireland amounting alone to about £50,000. During the reign of Charles I. the proceeds of the customs were nearly quadrupled, but it was found necessary to raise £120,000 by yearly subsidies of £40,000. According to the report of the committee appointed by Cromwell to inquire into the financial condition of Ireland, the revenue in 1654 was £197,304 and the expenditure £630,814, 9s. 8d. At the Restoration the Irish parliament granted an hereditary revenue to the king, an excise for the maintenance of the army, a subsidy of tonnage and poundage for the navy, and a tax on hearths in lieu of feudal burdens. "Additional duties" were granted shortly after the Revolution. "Appropriate duties" were imposed at different periods; stamp duties were first granted in 1773, and the post-office first became a source of revenue in 1783. In 1706 the hereditary revenue with additional duties produced £394,324, 11s. 3d., and for the two years ending in 1729 the amount was £889,351, 4s. 11¾d. Returns of the ordinary revenue were first presented to the Irish parliament in 1730. Table XXXIII., compiled from the statistics of M. Moreau, gives the annual average amount in Irish currency of net and gross produce of the revenue during every ten years up to 1789, the amount for 1790, and the annual average for the ten years 1792–1801. Table XXXIV., compiled from special and other returns presented to the House of Commons, gives the net produce of the excise and customs at intervals from 1720, and of the other branches of ordinary revenue at intervals from the time when they were first imposed. A special return in *Accounts and Papers*, 1868–69, gives in British currency the annual net public income and expenditure of Ireland from the Revolution to the Union, and Table XXXV., compiled from this return, gives its amount at various intervals between these periods. Table XXXVI., compiled from certain special returns presented to the House of Commons at different periods, gives the net annual income and

expenditure at certain intervals from the Union up to 1868.

Returns of the produce of the revenue were annually presented to parliament up to 1870, and, although they have been discontinued since that period, a special return from 1871 to 1875 was presented in 1876, and special returns were also presented in 1878 and 1879, the latter returns, however, not including the produce of the income tax from the income of officials. According to these returns the net produce of the revenue was in 1870 £7,287,127, in 1871 (not including that of the post-office) £7,291,393, 15s. 4d., in 1875 £7,970,050, 13s. 7d., and in 1879 £6,616,455. The revenue of England in 1879 amounted to £54,456,718, and of Scotland to £7,719,500.

No separate post-office returns have been published since 1870. In 1860 the gross produce of the sale of crown lands amounted to £15,537, and the annual income of land revenue to £48,358; in 1870 they were respectively £1283 and £45,000, and in 1880 £3506 and £41,589. The items of the expenditure of the exchequer of Ireland for 1868 (the last year for which returns are given) are—interest of public funded debt payable in Ireland, £1,188,654; other payments in connection with the consolidated fund services, £278,015; army, £3,560,000; miscellaneous civil services, £1,594,525. Since 1817 the public debt of Ireland on account of the consolidation of the British and Irish exchequer has ceased to form a separate item in the national account. Table XXXVII. shows its progress from 1716 till that period.

Banking.—A notice of the banks of Ireland will be found in the article BANKING, vol. iii. p. 290. The deposits in joint-stock banks amounted in 1840 to £5,567,851, in 1850 to £8,268,838, in 1860 to £15,609,237, in 1870 to £24,366,478, and in 1880 to £29,350,000. The deposits in trustees' savings banks in 1846 amounted to £2,855,827, but in 1850 had declined to £1,291,798; in 1860 the amount was £2,143,282, in 1870 £2,054,907, and in 1880 £2,100,165. The deposits in post-office savings banks in 1862, the year in which they were founded, were £78,696, in 1870 £583,165, and in 1880 £1,229,000. The amount of Government and India stock held in Ireland amounted in 1870 to £36,549,000, and in 1880 to£33,113,000.

National Wealth.—From a variety of circumstances it is difficult to arrive at an approximate estimate of the wealth of Ireland; and there is no proper basis for a comparison with the other portions of the United Kingdom—among other reasons from the fact that by far the largest part of the wealth of Ireland is derived from agriculture. The Tenement Valuation Act, passed in 1846 and amended in 1852, according to which the property of Ireland is rated for purposes of local and imperial taxation, has the disadvantage of having been applied in different parts of the country at different periods, and in the southern and western counties at a time when the value of property on account of the famine had very much deteriorated. No provision except of an optional kind has been made for a revaluation of property other than buildings and similar external additions to the value of the soil. It is probable therefore that the present valuation,

which is a little short of £14,000,000, is deficient by about £5,000,000. The case of Ireland is also exceptional from the large amount of wealth that immediately after it is produced is removed to be spent elsewhere, and of capital invested in Irish undertakings which is held by persons who do not reside in Ireland. The value of the agricultural produce and stock, the chief item of the wealth, is of course variable, and the rise in value is due solely to increase of price and to increase in the number of live stock, which of course represents the produce of more than one year. It is also a fallacious method of calculating its value to add that of produce and live stock together, as a great part of the produce is employed in feeding the live stock. In Ireland a considerable amount of money is probably hoarded privately, and the increase of deposits in banks can scarcely be regarded as altogether a symptom of prosperity, as the money thus deposited might in most cases be more advantageously employed by the farmer in improving his land. On the other hand, since the passing of the Land Act of 1870, indebtedness has largely increased among the farmers. A method of estimating the capital of Ireland has been employed by Dr. Hancock from the amount of capital passing annually under probate of wills and letters of administration, calculating this capital as 2·66 per cent. of the whole. Table XXXVIII., formed according to this method, shows the annual average amount of capital from 1826 at various periods of five years, and the amount of capital possessed by each head of the population, this being reckoned according to the year most nearly corresponding with those for which the average is given.

Railways.—The railway from Dublin to Kingston, which was opened in the end of 1834, was the first and for several years the only railway in Ireland. The progress of the railway system from that period is shown in Table XXXIX. For a comparison with England and Scotland, see ENGLAND, vol. viii. p. 215; it will be observed that the proportion of traffic in relation to population is very much smaller in Ireland.

Vital Statistics.—In the *Transactions of the Royal Irish Academy* for 1865, part iii., will be found an account by W. H. Hardinge of a copy which he accidentally discovered of a manuscript census survey of Ireland arranged in counties, baronies, parishes, and townlands, and in cities, parishes, and streets, and belonging in all probability to the year 1659. The population of Leinster is there given as 155,534, of Ulster as 103,923, of Munster as 153,282, of Connaught as 87,352, making a total for Ireland of 500,091. This is the only census return made by Government previous to 1821. Table XL. gives the different parliamentary returns and also various estimates or returns for previous years, to some extent reliable, but either inferential or made in such a manner as to render a very near approach to accuracy impossible. The Government returns are also deficient in accuracy until 1841, but from the table a fairly correct idea may be formed of the growth of the population up to 1841, while it affords a very accurate representation of its decline from that period. Table XLI. exhibits the population of each province for the years in which Government returns have been made; and Table XLII. shows the number of each sex from 1841.

The great increase of population which began towards the close of last century, and continued during the first forty years of the present one, was due in various degrees to improvements in the political condition of the country, to the creation of leaseholds after the abolition of the forty shillings franchise, and to the prosperity caused by the productiveness of the potato and the high prices of produce during the war with France. The decrease from that period began at first with great rapidity owing to the pressure of famine, and has been continuous up to the present time, chiefly owing to the creation of large pastur-

age farms, Table XLIII. gives the rate of increase or decrease per cent. in the various decades from 1821 to 1881. Table XLIV. gives the proportion of population to the square mile for each county from 1841.

The figures for 1841 indicate a density of population which is unparalleled, considering that it is so largely rural. Table XLV. gives the numbers of the rural and urban population, including the military, for 1841, 1851, 1861, and 1871. The collective population in the parliamentary boroughs was 804,705 in 1841, 878,430 in 1851, 788,866 in 1861, 856,788 in 1871, and 892,505 in 1881. The increase of the urban population between 1841 and 1851, while there was a large decrease in the population generally, was apparently owing to a temporary influx of the rural population into the towns, as in 1861 a large diminution had taken place, the increase of manufactures, however, causing the loss to be nearly recovered in 1871. Excluding the Dublin suburban townships of Rathmines (24,245) and Pembroke (23,184), there were only six towns whose population in 1881 was over 20,000; Table XLVI. gives their population in the census years from 1841 to 1881. The most noticeable features of the table are the rapid rise of Belfast owing to its prosperous linen trade; the steady progress of Londonderry, also situated in the thriving province of Ulster; the almost stagnant position of Dublin; and the decline of Cork and Limerick, both situated in Munster, the province in which both trade and agriculture are in the most backward condition. Table XLVII. gives a classification of the population according to occupation.

The population of Ireland has at various periods been considerably diminished by outbreaks of pestilence and by famine, but its decrease is chiefly attributable to emigration. Since 1847 this has been annually so great as to cause a continuous diminution of the population. The census commissioners estimated the emigration between 1821 and 1831 at 70,000. The total number who emigrated between 1831 and 1841, according to information collected at the various ports, and corrected by comparison with other statistics, was 403,459 (with an addition of 10 per cent. on account of imperfect returns), the number who emigrated from Irish ports being 214,047, and from Liverpool 152,738. Information as to the destination of the emigrants for these years is available only in regard to those emigrating from Irish ports, the numbers who left for British America being 189,225, for the United States 19,775, for the Australian colonies 4553, and for other destinations 494. The census commissioners of 1851 obtained information from the different ports of the United Kingdom regarding the numbers and destination of Irish emigrants from 1841 to 1855. The returns of emigration and immigration from and into the United Kingdom give full information regarding the destination of emigrants of Irish birth from 1853. Table XLVIII., compiled from the statistics of the census commissioners, and from the emigration returns, will show the character of the emigration movement, both as to the number of persons of Irish birth emigrating from the United Kingdom at different periods and as to their destination.

The influence of the great famine is very evident in the numbers emigrating between 1846 and 1852, the average being three times that of the preceding period, and more than double that of the period from 1853 to 1860. Although also the impulse towards emigration had begun even before 1846, and must be regarded as part of a general tendency towards emigration then prevalent in Europe, and especially in the United Kingdom, it was doubtless strengthened in Ireland by special circumstances which are still operating so as to cause an annual diminution of the population. The number who emigrated in 1841 was only 16,376, and in 1847 it rose to 215,444, more than double that of 1846. The highest number in any year was 249,721 in 1852, and the smallest since 1852 was 22,831 in 1877, the numbers increasing in 1879 to 41,296, and in 1880 to 93,641. This table, however, gives the number of emigrants not from Ireland but from the United Kingdom, and of course includes many of Irish birth who had been for some time living in Great Britain.

The Irish emigration returns, which commence from the 1st May, 1851, give the numbers of natives of Ireland who emigrated direct from the country—whether by Irish or British ports—but include those also who emigrated to settle in Britain, and until 1876 gave no information as to the several destinations of the emigrants. Table XLIX. shows the amount of general emigration from Ireland and from its various provinces from 1st May, 1851, to 31st December, 1879. The number of emigrants in 1852 was 190,322, the annual average for the three years 1852–1854 being over 170,000, from 1855 to 1862 the average was about 80,000, but it rose to 110,000 for 1863–65. From 1865 to 1874 it was about 70,000, in 1876 it was only 37,587, in 1879 it was 47,065, and in 1880 it increased to 95,517. There are no direct means of obtaining information as to the numbers who emigrated to settle in Britain before 1876, but a comparison between the numbers who emigrated from Ireland both to Britain and to foreign countries with those who emigrated from the United Kingdom to foreign countries shows that the number who settled in Great Britain between 1852 and 1880 was about 300,000. The percentage of those who have settled in Britain between 1876 and 1880 was 38. Apparently, however, for several years, the deaths of Irish-born persons and their emigration from Great Britain have more than counterbalanced the influx into it of Irish intending to settle, for, while the number of Irish resident in Great Britain, which in 1841 was 419,256, had increased by 1851 to 733,866, and by 1861 to 811,251, it had diminished by 1871 to 778,638. On the other hand, there has been a gradual increase in the number of British-born immigrants to Ireland, as is seen from Table L.

More than two-thirds of those leaving Ireland for foreign countries emigrate direct to the United States, but to these must be added the large numbers who sail to Canadian ports, and journey thence by rail. From May 5th, 1847, to June, 1880, according to records of the city, the arrivals of natives of Ireland direct to New York were 2,042,046, the arrivals from all countries being 5,857,025. The total number of Irish-born persons registered, whether in Ireland or foreign countries, about 1871 was 8,506,511,—that is, a larger number than the population of Ireland in 1841, and exceeding the population of 1871 by more than 3,000,000. The proportion of emigrants from Ireland who were laborers was 52·6 per cent. in 1877, 60·4 per cent. in 1878, 66·1 per cent. in 1879, and 72·1 per cent. in 1880. Until 1864, when the Act for the registration of births and deaths came into operation, no reliable information was obtainable as to the excess of the one over the other, and of course the large amount of emigration to some extent renders comparison with other countries impossible, as to the inferences to be drawn from the proportion of births and deaths to the population. Table LI. gives the yearly average of marriages, births, deaths, and emigrants for the ten years 1870–79, the numbers for 1880, and the rate per 1000 of estimated population.

The usual theory that the poverty of the Irish is due to

early marriages, or to the fact that a larger number marry than in Scotland or England, can be proved by statistics to be wholly unfounded. The average annual number for the ten years ending in 1879 of male minors married was only 2·65 per cent. of the total males married, and in the case of females the percentage was only 12·26, a much smaller proportion than in Great Britain; and in 1871 the proportion per cent. of the unmarried population above fifteen years was in Ireland—males 47·85, females 42·38, the proportion in England and Wales being 38·40 and 36·14 respectively, and in Scotland 44·41 and 42·23. In proportion to the number of married women between seventeen and fifty-five years of age, the number of births is very similar to that in Great Britain. The number of illegitimate births is very small, the yearly average for the last ten years being about 2·5 per cent. The proportion of the sexes born is about 106 males to 100 females.

Table LII. gives the average annual number of deaths from each of the principal zymotic diseases and from all causes for 1870–79, and also the number for 1880. Table LIII. gives the number of deaths from all causes for four decades, and the number from zymotic diseases, with the percentage from these diseases to the total number of deaths; and Table LIV. shows the number suffering from the various kinds of serious bodily or mental infirmities in 1851, 1861, and 1871. The total number of deaths in the decade ending in 1881 was 969,110.

The mortality of Ireland is considerably under that of Great Britain, and at the time of the census of 1871 a larger percentage of the population were over sixty years of age. The rate of mortality is no doubt affected by emigration, but its smallness in Ireland is perhaps due to the large proportion of the rural population. At various periods the mortality has been largely increased by famine, and it is also influenced by the insufficient diet and clothing of many of the inhabitants.

Government.—The executive government is vested in a lord-lieutenant, assisted by a privy council, and by a chief secretary, who is a member of the House of Commons and frequently also a member of the cabinet. In the absence of the lord-lieutenant his functions are discharged by lord-justices, those generally appointed being the lord-chancellor and the commander of the forces. Each county is in charge of a lieutenant, a number of unpaid deputy-lieutenants and magistrates, and one or more resident paid magistrates, all appointed by the crown. The counties of cities and towns and the boroughs are governed by their own magistrates. The judicial establishment consists of the high court of chancery, the courts of Queen's bench, common pleas, and exchequer, the landed estates court, and the probate and matrimonial court, which since 1877 constitute the high court of justice; the court of appeal; the high court of admiralty, which is to be abolished after the death of the present judge; and the court of bankruptcy and insolvency. The decisions of the court of appeal are subject to an appeal to the House of Lords. Assize courts are held in each county by two judges, for which purpose the county is divided into six circuits.

1880	20,390	128,010	102,955	95,517	3·83	24·0	19·3	17·9

Ireland is represented in the imperial parliament by 28 temporal peers elected for life and 103 commoners,—the counties being represented by 64 members, the small boroughs by 25, Dublin, Cork, Limerick, Waterford, Belfast, and Galway by 2 each, and the university of Dublin by 2. In 1850 the franchise in county elections was extended to occupiers of any tenement assessed for poor rates at a net annual value of £12 and upwards, and also to owners of certain estates of the rated net annual value of £5. In 1868 the franchise in boroughs was extended to occupiers rated at and above £4, and a lodger franchise was also introduced, granting votes to occupiers of lodgings of a clear yearly value, if let unfurnished, of £10 and upwards.

In Ireland there are four military districts, the headquarters of these being Dublin, Cork, Curragh, and Belfast respectively, and eight military subdistricts, with depôts at Downpatrick, Omagh, Armagh, Naas, Birr, Galway, Clonmel, and Tralee. The Irish militia consists of 12 regiments of artillery, 21 regiments of infantry, and 14 rifle corps, numbering when embodied over 31,000 men and officers.

The parish constables of Ireland were in 1814 superseded in proclaimed districts by a peace preservation force, and in 1822 an Act was passed authorizing the formation of a constabulary force of 5000 men, under an inspector-general for each province. In 1836 the entire force was amalgamated under one inspector-general. In all, it numbers between 10,000 and 12,000 men. In addition to the usual duties of policemen, the police are entrusted with the collection of statistics, the preservation of fish and game, and a variety of services connected with the local government. The average annual expense is a little over £1,000,000. In addition to this force there is the Dublin metropolitan police, consisting of about 1100 officers and men, who are maintained at an annual cost of over £130,000, the expense born by the Consolidated Fund being over £80,000.

Crime.—Table LV. gives the number of persons in Ireland sent for trial by jury, and the numbers convicted and acquitted, for every fifth year from 1845 to 1875, and also for 1878 and 1880.

These figures show a very rapid decrease of crime between 1850 and 1855, and a gradual and considerable decrease since that period, partly but not altogether attributable to the decrease in the number of the population. The large number of committals in 1850 and previous years was chiefly owing to the distress then prevailing in the country. A very noticeable feature of the statistics is the large proportion of acquittals.

In regard to the more serious crimes, the proportion of offences against the person as compared with that in England is very large, and of offences against property and against the currency very small, the latter fact being doubtless owing to the small proportion of the town population. The proportion for all Ireland of indictable offences not disposed of summarily was 15 in 10,000 of the population in 1879, while in Dublin it was 110 in 10,000.

Table LVI. gives the number of offences in Ireland for 1879 according to three classes, and the corresponding numbers for 1878 in England and Scotland for an equal population.

TABLE LII.—*Annual Average of Deaths from the eight principal Zymotic Diseases and from all causes.*

	Smallpox.	Measles.	Scarlet Fever.	Diphtheria.	Hooping Cough.	Fever.	Diarrhœa.	Cholera.	Total.	All causes.	Percentage of eight Zymotics.

Of the minor offences in Ireland over 99,000 were cases of drunkenness, considerably more than double the number of cases in England or Scotland, which were pretty nearly equal. Table LVII. gives the number of agrarian offences from 1870.

Poor Law Authorities.—The legislation connected with making provision for the poor of Ireland dates from 1771, when an Act was passed by the Irish parliament under which 11 houses of industry were erected, 8 in Munster, and 3 in Leinster. The amount of expenditure sanctioned by the Act was £14,400 a year, and probably it always came short of this by at least £10,000. Additional powers were conferred on county authorities in 1806 and 1818, but according to the select report of the House of Commons in 1830 no addition had been made to the houses of industry up to that period. An Act was, however, passed in 1838, which contained the important provision that if the local authority failed to carry the law into effect they might be superseded by paid vice-guardians. The Act came into operation in 1840, and an Outdoor Relief Act was passed in 1847. Full details regarding subsequent additions to the Act, as well as in reference to the whole subject of Irish local government, will be found in the paper by Dr. Hancock contributed to *Cobden Club Essays*, 1875. Table LVIII. gives the number of unions for every ten years from 1840 to 1870, and for 1878 and 1879, with the number of outdoor and indoor paupers, and the total expenditure. The figures show a much smaller proportion of paupers compared with population than the corresponding statistics of England and Scotland,—Scotland notwithstanding its smaller population having nearly one-third more paupers, while England has actually about twelve times as many. The difference is to be accounted for by the smaller town population of Ireland, the simpler habits of the Irish, and the prevalence of mendicancy. It is only indeed in years of exceptional famine that there is any great demand on the public purse for the support of the poor; the duchess of Marlborough's relief fund, 1879–80, amounted to £135,000, and the Mansion House fund to £180,000, probably over £400,000 being spent directly on relief, in addition to the sums advanced on loan for relief works. By the Medical Charities Act, passed in 1851, boards of guardians were empowered to form the poor law unions into dispensary districts subject to the control of the poor law commissioners. The number of dispensary districts is 720, with nearly 1100 dispensaries and about 800 medical officers. Each district is placed under a committee of management, consisting of the guardians of the unions, the *ex-officio* guardians who reside and have property in the district, and a number of ratepayers elected by the board of guardians, the number of each committee being fixed by the commissioners. The average annual expenditure under this Act during the five years ending 1880 was over £140,000, and the average number of cases very nearly 700,000. The average number of insane in Ireland during the same five years was over 19,000, of which number the average in asylums was over 8000, and in workhouses over 3000. For further information regarding the whole subject of Irish pauperism and lunacy the reader is referred to the Report of the Poor Law Union and Lunacy Commissioners in vol. xxii. of *Accounts and Papers*, 1878–79.

County Authorities.—For purposes of local taxation Ireland is placed under the authority of baronial presentment sessions and juries. The former are for baronies or half-baronies, baronies corresponding to the ancient territories inhabited by distinct tribes or families. The number of these sessions is 326, and they are composed partly of justices of the peace and partly of ratepayers, the number of whom is fixed by the grand jury of each county. Since 1836 they have had the primary decision of all questions as to roads and bridges. The power of imposing county rates is, except in the case of the county of Dublin, exercised by the grand juries either at the assizes in the several counties at large, or at the assizes in the several counties of cities and towns. In the county of Dublin this authority is vested in the Easter term grand jury in the court of Queen's bench, and in the case of the cities of Dublin, Cork, and Limerick it has since 1850 been vested in the town councils. The tax levied under the vote of the grand juries is called grand jury cess, and is employed for the maintenance of roads, and the defrayment of the expenses incurred by the maintenance of laws and the administration of justice. Infirmaries and hospitals are supported by grand jury presentments, aided by treasury grants, and by subscriptions, donations, and bequests. The origin of the grand jury cess dates from the time of Charles I., when the justices were directed to tax the inhabitants for the maintenance of bridges, with the assent of the grand juries. At the beginning of the reign of George III. power was granted to the grand juries to make presentments also for roads. At first the rate was applied only to the maintenance of cross roads, but in 1857 the turnpike system applicable to main roads was abolished. This early accidental legislation in reference to roads has given Ireland at least one solitary advantage over Great Britain which it still retains.

Authorities for Groups of Counties.—These consist of governors of district lunatic asylums and the trustees of inland navigation and arterial drainage. The asylums number 22 in all, and the governors are nominated by the lord-lieutenant. The navigation works in Ireland were executed at the time of the famine of 1846, and their management is placed under a board of trustees originally named by Act of Parliament, the vacancies being filled up by the grand juries.

[1] Including seamen at sea on census night.

[2] Including 453 Jews and 1144 who refused information.

Town Authorities.—The towns of Ireland were under the government of close corporations until 1829, when they were allowed to adopt popular constitutions. By the Municipal Act of 3d & 4th Vict., the towns containing upwards of 12,000 inhabitants are divided into wards, and are governed by a council consisting of a chief magistrate called mayor, that of Dublin being styled lord mayor, and a certain number of aldermen and councillors for each ward. Eighteen towns are governed according to the act of 9th George IV., and more than 80 have adopted the Towns Improvement Act of 1854. Additional powers were conferred on town authorities by the Local Improvement (Ireland) Act of 1871.

Harbor Authorities are distinct from the town authorities, and consist of a board chosen in accordance with certain special acts.

The town authorities, or in counties the poor law guardians, have the power to constitute themselves a burial board for the purpose of levying rates, to be used in the maintenance of old burial grounds or the purchase of new ones.

By an Act passed in 1872 the functions previously performed by the lord-lieutenant, the privy council, and the chief secretary in reference to local government were transferred to a local government board, formed out of the poor law board which it superseded.

Taxation.—The local taxation of Ireland amounted in 1866, the first year for which returns are available, to £2,538,280, in 1870 to £2,728,327, and in 1879 £3,368,113. The following are the separate items for 1879:—grand jury cess, £1,128,192; fees of the clerks of the peace (exclusive of salary), £11,585; fees of the clerks of the crown, £2884; petty session stamps and crown fines, £65,086; dog license duty, £35,945; Dublin metropolitan police taxes, £44,965; court leet presentments, £293; harbor taxation, £380,350; inland navigation, £5679; town taxation under town authorities, £622,871; burial board taxes, £3185; poor rate and local receipts, £1,031,992; light dues and fees, under Merchant Shipping Act, and bridge and ferry tolls, £35,086. The amount of rates on real property was £2,619,183, or 77·8 per cent. of the whole; tolls, fees, stamps, etc., £539,174, or 16·0 per cent.; and other receipts, £209,756, or 6·2 per cent. The amount granted from the imperial revenue in aid of local taxation in 1880–81 was £1,856,743, in addition to which an annual sum, £1,189,461 in 1880, is advanced on loan by the Commissioners of Public Works from the Consolidated Fund, while £883,116 was advanced in 1880 from the Irish Church Fund.

Religion.—According to the census returns of the commissioners of public instruction in 1834, out of a total population of 7,943,940 inhabitants 852,064 belonged to the Established Church, the number of Roman Catholics being 6,427,712, of Presbyterians 642,356, and of persons of other denominations 21,808. Table LIX. gives returns for 1861 and 1881.

The annual average number of marriages according to the forms of the Episcopalian Church for the ten years 1869–78 was 4208 and for 1879 it was 3646,—the numbers according to the Presbyterian form being 2556 and 2214 respectively, in other registered buildings 308 and 338, and according to the rites of the Roman Catholic Church, 18,567 and 16,578.

The Anglican Episcopal Church of Ireland constituted until 1871 an integral portion of one church, known as the Church of England and Ireland, and established by law in the two countries; but the Irish branch was disestablished and disendowed by an Act which received the royal assent on July 26, 1869. According to this Act, which came into execution on January 1, 1871, all church property became vested in a body of commissioners. All the state grants were to be resumed by the state, provision being made for vested interests, but the church was to receive possession of all endowments obtained from private sources since 1660. To all incumbents the income they formerly possessed was secured for life, minus the amount they might have paid for curates; and compensation was also granted to curates, parish clerks, and sextons, to Maynooth Roman Catholic College in lieu of the continuance of the annual parliamentary grant, and to the Presbyterians in lieu of the continuance of the grant called "Regium Donum."

TABLE LX.—*Contributions to Stipend Fund, etc., 1876–79.*

1876.		1877.		1878.		1879.	
Stipend Fund.	All Sources.	Stipend Fund.	All Sources.	Stipend Fund.	All Sources.	Stipend Fund.	All Sources.
£124,424	£212,095	£118,478	£197,739	£115,558	£159,403	£108,272	£165,007

According to the report of the commission appointed to inquire into the revenues of the Established Church, *Accounts and Papers*, 1867–68, the net annual produce and value of the entire property was found to be £616,840, of which the value of the houses of residence and the lands in possession of the clergy was £32,152. The total sum paid or payable by the commissioners of church temporalities as compensation in connection with the operation of the Irish Church Act is estimated at £11,666,518. To meet the demands upon them the commissioners borrowed £9,000,000 from the National Debt Commissioners. The total sum obtainable by sales of church property is £9,794,790, of which £3,362,648 has been received in cash, the balance, except £797,766, which is secured by mortgage, being payable in terminable annuities. In addition to this there is a permanent income consisting of tithe rent-charges and perpetual rents estimated at £293,455. The work of the commissioners has now been practically completed, and according to their report for 1869–80 the estimated value of the estate is now £12,189,728, exclusive of £200,000, the value of uncommuted glebes and uncollected arrears. The annual income at present is £574,219, but by the termination of annuities it will gradually diminish until 1932, when there will still be the permanent income of £293,455. But for additional burdens laid upon the estate its entire debt would at the end of 1880 have been £5,900,000, leaving a surplus of £6,500,000. These burdens are a sum of £1,000,000 for intermediate education, £1,300,000 to form a pension fund for national school teachers, and the interest at 3½ per cent. of £1,500,000 advanced on loan for the purposes of the Relief of Distress (Ireland) Acts, 1880, and involving a loss to the estate of £543,345.

Before its disestablishment the Church of Ireland consisted of 2 archbishoprics, 10 bishoprics, 30 corporations of deans and chapters, 12 minor corporations, 32 deaneries, 33 archdeaconries, 1509 incumbencies, with 500 stipendiary curates. A general convention of the clergy to reorganize the church and to choose a representative body to manage its secular affairs met in February, 1870, and the church is now constituted as the Church of Ireland. The amount received from the commissioners for commutation of life interests up to 31st December, 1879, was £7,577,477, 6s. 8d., chargeable with annuities amounting to £592,075, 5s. 8d., and of this sum there remained at the end of 1879 £2,783,871, 11s. 8d., chargeable with annuities amounting to £201,824, 8s. 9d., the annuities extinguished by composition and advances amounting to £294,054, 9s. 4d. The sums invested by the church in securities amounted to £6,362,433, 17s. 5d., yielding an income of £281,577, 11s. 8d., in addition to which £109,162, 10s. has been advanced to the clergy on policies of insurance. The balance of the general sustentation fund amounted to £194,125, 12s. 8d., yielding an interest of £7753, 7s. 9d., the unappropriated balance of which was £963, 7s. 9d. The sum expended on the purchase of glebes has been £499,589, 16s. 10d. of which £214,900, 10s. 8d. has been subscribed; and the net amount received from the sale of glebes was £45,588, 10s. 3d. The contributions to the stipend fund, and the total contributions from all sources from 1876 to 1879, are shown in Table LX. For fuller financial details the reader is referred to the annual report of the representative body and to the *Irish Church Directory*.

The Roman Catholic Church is governed by 4 archbishops and 27 bishops, the number of parish priests being nearly 1000, and of administrative curates about 1750. The ecclesiastical parishes amount to 1084, and the churches and chapels number nearly 2500. The Maynooth Roman Catholic College, which was founded in 1795, originally

received an annual vote from Government of £8000, but latterly a grant from the consolidated fund of £26,360, which was commuted by the payment of £372,331.

The Presbyterian Church, which has its principal adherents in Ulster, was originally formed in 1642, and in 1840 a union took place of two divisions of the church which had formerly separated. Previous to the disestablishment of the Church of Ireland, the Presbyterians received for the support of their ministers an annual sum, first granted in 1672, of about £40,000, known as "Regium Donum," which was commuted by the Church Disestablishment Act. The church embraces 36 presbyteries and nearly 600 congregations, the number of families connected with the church in 1880 being 79,214, and of communicants 104,769. The total sum at the disposal of the church in 1880 was £139,840, the sum paid to ministers being £44,922. Candidates for the ministry are trained at Magee College, Londonderry, and at the Presbyterian College, Belfast.

The Methodist Church of Ireland was formed in 1878 by the union of the Wesleyan Methodists with the Primitive Wesleyan Methodists. The number of ministers connected with the Conference in June, 1880, was 240, of whom 40 were supernumeraries. The number of principal stations under the charge of ministers was 135, embracing 373 chapels. The number of attendants on public worship was stated to be 60,541, and the membership 24,463. The home mission fund, with an augmentation from the English Conference, amounted to £13,241, and the sum raised for foreign missions to £5533. There is a Methodist college at Belfast for the training of students who have been accepted as candidates for the ministry.

The number of persons connected with the other denominations of Ireland is inconsiderable, amounting in 1881 to only 0·8 per cent.

Education.—Table LXI. shows the proportion per cent. of persons in Ireland who could read and write, who could read only, and who could neither read nor write at the various census periods. The number of persons in 1871 who could speak Irish only was 103,562, the number in 1841 being 319,602, and the number who could speak both Irish and English was 714,313 in 1871 and 1,204,684 in 1841.

TABLE LXII.—*National Schools in Ireland, 1833–80.*

1860	5,632	804,000	270,722	1880	7,590	1,083,020	722,366

According to the census of 1871 the number of schools for primary instruction was 9495 with 615,785 pupils, of superior schools 574 with 21,225 pupils, of universities and colleges 13 with 2945 students. The oldest university is that of Dublin, established in 1591 by a charter of Queen Elizabeth. The course of study includes mathematics, classics, modern languages, English, logic, ethics, astronomy, experimental science, and natural science. The Catholic University, founded in 1854, has in operation faculties of medicine, philosophy and letters, and science. Queen's University, established in 1850, with colleges at Belfast, Cork, and Galway, has faculties of law, arts, medicine, and engineering. Queen's University will be shortly superseded by the Royal University, for which a charter was granted in 1880. A royal college of science was established in 1867, with departments of mining, agriculture, engineering, and manufactures. The higher education of women is represented by Alexandra College, Dublin, founded in 1866, the Governess Association, the Ladies' Institution of Belfast, and the Queen's Institute for the instruction of women. A list of colleges and intermediate schools will be found in the *Intermediate Education Year Book and Directory*. By the provisions of the Intermediate Education (Ireland) Act, 1878, a sum of £1,000,000 of the Irish Church surplus was set apart for the encouragement of intermediate education in Ireland, the money being expended partly in exhibitions and prizes to students, and partly in the payment of results fees. The total number of pupils examined in 1880 was 5561—4114 boys and 1447 girls, the number who passed being 2899 boys and 1111 girls. Exhibitions of the value of £20 a year for three years were awarded to 96 boys and 40 girls in the junior grade; in the middle grade 32 boys and 13 girls received exhibitions of £30 annually for two years; and in the senior grade 16 boys and 4 girls received exhibitions of £50 for one year. In addition to this 558 boys and 726 girls received prizes in books.

In 1811 a society was formed in Ireland for the education of the poor, which from 1819 received the assistance of a grant of public money. This, however, was withdrawn in 1830 on account of the Roman Catholics refusing from religious objections to allow their pupils to enter the schools of the society. In 1833 the money formerly given to the society was vested in commissioners of public educa-

tion, who in 1845 were incorporated under the name of the "Commissioners of National Education of Ireland."

Table LXII. will show the progress of national education in Ireland from 1833 to 1880; and Table LXIII. gives particulars as to school attendance for 1880.

Table LXIV. shows the Protestant and Roman Catholic attendance at the 4175 mixed schools from which returns were received.

The unmixed schools numbered 3331, of which those taught by Roman Catholic teachers numbered 2779, the number of pupils being 441,612, while those taught by Protestant teachers numbered 552, the total number of pupils being 63,983, of whom 26,283 belonged to the Church of Ireland, 34,348 to the Presbyterian Church, and 3352 to other denominations. Table LXV. shows the attendance at the various classes in the national schools in 1880.

The number of district and minor model schools in 1880—exclusive of those of the metropolitan district—was 26, the number of pupils on the roll 16,997, and the average attendance 8971. Table LXVI. shows the relative proportion of attendance at the various classes.

The workhouse schools under the superintendence of the National Board in 1880 numbered 158, the pupils on the roll being 16,945, and the average attendance 8880. There were 52 industrial schools in 1879, the number of inmates being 4979, and the expenditure £117,888. The number of school farms connected with the national schools in 1880 was 94, and of school gardens 19, in addition to which there are a large number of agricultural schools under local management, and a large number of pupils were also taught agriculture in the national schools, the total number of pupils who presented themselves for examination in agriculture in 1880 being 33,648, of whom 15,652 passed. The number of pupils who presented themselves at the results examination in the national schools in 1880 was 461,574, of whom 340,871, or 73·8 per cent., passed. Table LXVII. shows the various classes of teachers under the National Board in 1880.

In addition there were 85 junior assistants, 227 work mistresses and industrial teachers, 90 temporary assistants, and 8 temporary work mistresses. The payment to the teaching staff for the year ending 31st March, 1881, was £737,631, 4s. 3d. The amount of money raised by school fees was £91,300, 5s. 8d., by subscription £40,516, 6s. 10d., by local rates £8324, 6s. 7d. The whole amount received from the Board was £597,490, 5s. 2d. The amount of subscriptions other than local for the four years ending 1880 was £151,698, 16s. 6d., which was devoted to building purposes. The total amount of the parliamentary grant for the promotion of education, science, and art in Ireland for the year ending 31st March, 1880, was £795,351.

For particulars regarding the endowments, funds, and actual condition of the endowed schools of Ireland, including the royal free schools, diocesan free schools, grammar schools, Erasmus Smith schools, and schools connected with the Church of Ireland, the Roman Catholic Church, and the various other denominations, the reader is referred to the *Report of the Endowed Schools (Ireland) Commission*, vols. i. and ii., 1881.

Antiquities.—The principal objects in Ireland of antiquarian and architectural interest are noticed under the various counties.

BIBLIOGRAPHY.

Geology.—The Government geological survey of Ireland, begun in 1832, was completed in 1881, and maps of separate portions have been published, accompanied with explanatory memoirs. Among the geological maps of the whole country may be mentioned that by E. Hull, London, 1878. The chief works on the geology of the country as a whole are Sir Richard Griffith's *Physical Geology of Ireland*, 2d edition, 1838; Hull's *Physical Geology and Geography of Ireland*, London, 1878; and Kinahan's *Manual of the Geology of Ireland*, London, 1878. An interesting notice of the principal features of Irish geology will be found in *Aus Irland*, by Dr. Arnold von Lasaulx, Bonn, 1877. A list of the more important papers on the special points of Irish geology is given in the work of Hull.

Agriculture.—For information regarding the character of the land systems of Ireland the reader may consult Godkin's *Land War in Ireland*, 1870; Sigerson's *History of Land Tenure in Ireland*, 1871; O'Curry's *Ancient Manners and Customs of Ireland*, 3 vols., 1873; the paper on "The Tenure of Land in Ireland," by Judge Longfield, in *Systems of Land Tenure*, published by the Cobden Club, 1876, and with additions in a new edition, 1881; Fisher's *History of Land Holding in Ireland*, 1877; O'Brien's *History of the Irish Land Question*, 1880; Richey's *Irish Land Laws*, 1880. The political-economy relations of the subject have been treated, among other writers, by John Stuart Mill, T. E. Cliffe Leslie, and Professor Cairnes. For general information a first place must be assigned to the evidence given before the Devon Commission, a *Digest* of which by J. P. Kennedy was published at Dublin in two parts, 1847–48, and the Report of the Bessborough Commission, 1881, and of the Commission on the Agriculture of the United Kingdom, 1881. Among other works are—Thornton, *Plea for Peasant Proprietors*, 1848; Duval, *Histoire de l'Émigration*, Paris, 1862; Dufferin, *Irish Emigration and the Tenure of Land in Ireland*, 1867; P. Lavelle, *Irish Landlords since the Revolution*, 1870; H. S. Thompson, *Ireland in 1839 and 1869*, 1870. The agricultural condition of the country has been described by such competent observers as M'Combie, Maclagan, and James Caird; and for minute details regarding it see the "Review of Irish Agriculture," by R. O. Pringle, in vol. viii., second series, of the *Journal of the Royal Agricultural Society of England*, 1872, and "Illustrations of Irish Farming," by the same writer, in vol. ix., 1873.

Manufactures and Commerce.—Lawrence, *The Interest of Ireland in her Trade and Wealth*, Dublin, 1682; *Discourse on the Woollen Manufacture of Ireland*, 1698; *An Inquiry into the State and Progress of the Linen Manufacture in Ireland*, Dublin, 1757; G. E. Howard, *Treatise on the Revenue of Ireland*, 1776; Hely Hutchinson, *Commercial Restraints of Ireland*, 1779; Lord Sheffield, *Observations on the Manufactures, Trade, and Present State of Ireland*, 1785; R. B. Clarendon, *A Sketch of the Revenue and Finances of Ireland*, 1791; Wallace, *Essay on the Trade and Manufactures of England*, Dublin, 1798.

Antiquities.—O'Donovan's edition of the *Annals of the Four Masters*; Weever, *Ancient Funeral Monuments*, 1767; Bush, *Hibernia Curiosa*, 1769; Grose, *Antiquities of Ireland*, 2 vols., 1791–95; Ed. Ledwich, *Antiquities of Ireland*, 1804; O'Brien, *Round Towers of Ireland*, 1834: G. S. Petrie, *Ecclesiastical Antiquities in Ireland*, 1845; Godkin, *Saxons in Ireland*, 1851; Id., *Ireland and her Churches*, etc., 1857; Keane, *Towers and Temples of Ancient Ireland*, 1867; Smiddy, *Essay on the Druids, Ancient Churches, and Round Towers*, 1873; Brash, *Ecclesiastical Architecture of Ireland*, 1874; Joyce, *Irish Names of Places*, 2d ed., 1870, 2d series, 1875; Lord Dunraven, *Notes on Irish Architecture*, 1877; H. Gaidoz, *Notice sur les Inscriptions Latines de l'Irlande*. Paris, 1878.

Miscellaneous.—An account of the condition of the country in the time of Henry II. is given by Giraldus Cambrensis in *Topographia Hiberniæ* and *Expugnatio Hiberniæ*, 1187; and in the time of Elizabeth, by Robert Payne, in "A Brief Description of Ireland," 1590, published in vol. i. of the *Tracts of the Archæological Association of Ireland*, 1841, and by Ed. Hogan in *Description of Ireland and the State thereof in 1598*, first published in 1878. The following works, which are included in *A Collection of Tracts and Treatises on Ireland*, published at Dublin, 1861, are invaluable for the information they afford in regard to the social and industrial history of the country:—*A View of the State of Ireland*, by Edmund Spenser, 1633; *A Discoverie of the State of Ireland*, by Sir John Davies, 1613; *The Political Anatomy of Ireland*, by Sir William Petty, 1691; *The Querist*, by Bishop Berkeley, 1735–37; *A Word to the Wise*, by the same, 1752; Prior's *List of Absentees*, 2d edition, with Appendix, 1729: *An Essay on the Trade of Ireland*, by Arthur Dobbs, Esq., 1729; *An Abstract of the Number of Protestant and Popish Families in Ireland*, 1726. The writings of Swift, especially his *Short View*, cast a variety of cross lights on different aspects of the subject. Among later works a first place must of course be given to the *Tour in Ireland*, by Arthur Young, London, 1780. *The Statistical and Political Account of Ireland*, by Edward Wakefield, London, 1812, is painstaking and accurate; and of similar value are Thomas Newenham's *View of the Circumstances of Ireland*, 1809; the same author's *Inquiry into the Population of Ireland*, 1805; and Mason's *Statistical Account*, 1814–19. The laborious work of M. César Moreau, *Past and Present State of Ireland examined in a Series of Tables*, published in lithograph, London, 1827, gives a comprehensive statistical history of the country for twenty years before and twenty years after the Union. Among more modern works are—*On Local Disturbances in Ireland*, by Sir G. C. Lewis, 1836; Sir Robert Kane, *The Industrial Resources of Ireland*, 2d edition, Dublin, 1845; George Lewis Smith, *Ireland Historical and Statistical*, London, 1844–49; Jonathan Pim, *Condition and Prospects of Ireland*, 1848; Gustave de Beaumont, *L'Irlande, Sociale, Politique, et Religieuse*, 1839 (English translation in the same year, and a 7th French edition in 1863); Hancock, *Report on the Supposed Progressive Decline of Irish Prosperity*, Dublin, 1863; J. M. Murphy, *Ireland: Industrial, Political, and Social*, 1870; Burke's *Letters, Speeches, and Tracts on Ireland*, edited by Matthew Arnold, 1881. Thom's *Irish Almanac* contains admirable digests of the parliamentary returns of the current years, as well as other statistical tables compiled from original sources. (T. F. H.)

PART II.—HISTORY.

Legendary History of Early Races.—Circumstances were favorable in Ireland to the growth and preservation of ethnic legends. Among these favorable circumstances were the long continuance of tribal government, and the existence of a special class whose duty it was to preserve the genealogies of the ruling families, and keep in memory the deeds of their ancestors. Long pedigrees and stories of forays and battles were preserved, but under the necessary condition of undergoing gradual phonetic change according as the popular language altered. During many centuries there had been no conquest by foreign races to destroy these traditions; internal conquests and displacements of tribes confuse but do not eradicate traditions and pedigrees. When the Irish were converted to Christianity and became acquainted with the story of the deluge, the confusion of tongues, and the unity of the human race, the súide (sages) naturally endeavored to fill up the gap between their eponyms and Noah. The pedigrees now began to be committed to writing, and, as they could for the first time be compared with one another, a wide field was opened to the inventive faculties of the scribes. The result has been the construction of a most extraordinary legendary history, which under the constant care of official súide acquired a completeness, fulness, and a certain degree of consistency which is wonderful. In the 11th and 12th centuries this legendary history was fitted with a chronology, and synchronized with the annals of historical nations. We may assume with confidence that a history of a group of tribes admittedly of diverse origins, consisting mainly of names of persons and battles transmitted by memory, must necessarily lack all proportion, not alone as regards absolute, but even as regards relative time; that personages and events may appear in the background that should be in the foreground, and the converse; nay, even that the same personages and events may figure at times and places far apart. Keeping these things in view, the *Lebar Gabhala*, or "Book of Invasions," a curious compilation, or rather compilations, for there are several editions of it, of the ethnic legends of Ireland, will help us to give the main facts of the early peopling of Ireland. Our guide records the coming of five principal peoples, namely, the followers of Partholan or Bartholomew, those of Nemed, the Firbolgs, the Tuatha Dé Danann, and the Scots or Milesians.

Partholan and his people came from Middle Greece, and landed at Inber Sceine, believed to have been the estuary of Kenmare. After occupying Ireland for three hundred years, they died of a plague, and were buried at Tamlecht Muintire Partholain, the plague Lecht or grave of Partholan's people, now Tallaght, near Dublin. This race divided the coast into four parts, their leader having had four sons. Thirty years after the destruction of Partholan's people, a race arrived from Scythia under a leader called Nemed, in thirty ships, each containing thirty warriors. We are not told where he landed, but like Partholan's people Nemed died of a plague at the hill upon which Queenstown in Cork Harbor is situated, and which has on that account been called Ard Nemeid. At this time another people appear on the scene, the Fomorians. It is probable, however, that Fomorian was merely a name for all sea-coming enemies, and that they were not always the same race. The descendants of Nemed's people suffered much hardship from them, we are told, but at length succeeded in destroying the fortress of their leader Conan at Tor Inis, now Tory Island, off the coast of Donegal, and killing himself and his children; but Morc, another leader, having arrived soon after from Africa with sixty ships, a second battle was fought, in which both parties were nearly exterminated. Morc, however, escaped, and took possession of the country, while of the Nemedians only the crew of one ship, having the usual number of thirty warriors—among whom were three descendants of Nemed himself—escaped. Each of the three descendants of Nemed went to a different country, and became the eponym of an important race. The five chiefs of the Firbolgs, the next colonizing race, appear to have landed at different places: one party, that of the Fir Galeons, landed at Inber Slangi, so called from their leader Slangi, whose name is still preserved in the river Slaney; another tribe, the Firbolgs, who gave their name to the collective tribes, arrived at what is now Erris in Mayo; and a third section, the Fir Domnand, landed at Tracht Rudraide in Ulster, so called from their leader Rudraide, or rather Rud. All these tribes seem to have been British, a view which is confirmed by their chief fort being Dind Rig, the dun or fort of the kings on the Barrow in Carlow, afterwards the seat of the kings of Leinster, a province which appears to have always had a close relationship with Britain. The Firbolgs had only effected settlements in the country, but had not brought the whole of it into subjection before the arrival of a new tribe called the Tuatha Dé Danann. According to the Nemedian legend, this new tribe was the race of Ibath, grandson of Iarbonel the prophet, son of Nemed. The new-comers under a king called Núadu demand the sovereignty of the country from the Firbolg king Eochaid Mac Erca, who refuses, and thereupon they fight a battle at Mag Tuired Conga, now Moytura near Cong in the county Mayo, the site of which is still traditionally remembered, and many graves belonging to the period of cremation have been found there. The Firbolgs were worsted in this battle, and, as in all ethnic legends, almost annihilated, and the remainder driven out of the country.[1] Thirty years after the conquest of the Firbolgs, the Tuatha Dé Danann fought a great battle with the Fomorians at another Mag Tuired, which is distinguished from that of Cong by being called the Northern. Its site is placed by tradition near Lough Arrow on the borders of Sligo and Roscommon, at a place where many graves and pillar-stones still exist.

The last of the prehistoric races of Ireland are the so-called Milesians or Scots. The immediate eponym of the new race was Galam from *Gal*, "valor," a name which might be expressed by the Latin *miles*, a "knight," whence came the names Milesius and Milesians. Among the names which appear in the pedigree, which is of course carried back without a break to Noah, are several worthy of the attention of archæologists,—namely, Breogan or Bregán, Eber Scot, Góedal Glas, Fenius Farsaid, Allait, Núadu, Sru, and Esru. Breogán, according to the legend, was the grandfather of Galam or Milesius, who founded Brigantia in Spain.

With all their drawbacks, the Irish ethnic legends, when stripped of their elaborate details and Biblical and classical loans, express the broad facts of the peopling of Ireland, and are in accordance with the results of archæological investigation. At the earliest period the country was well wooded, and the interior full of marshes and lakes; it was occupied by a sparse population, who appear in later times as "forest tribes" (Tuatha Feda), and were doubtless of the aboriginal (Iberic) race of western and southern Europe. The story of Partholan represents the incoming of the first bronze-armed Celts, who were a Goidelic tribe akin to the later Scots that settled on the sea-coast and built the fortresses occupying the principal headlands. They formed with the forest tribes the basis of the population in the Early Bronze age. Afterwards came the various tribes known by the general name of Firbolgs. It is not necessary to suppose that all the tribes included under this name came at the same time, or even that they were closely akin. The legend names several tribes and tells us that they came into Ireland at different places from Britain. The effect of their immigrations now appears to have been that in the north the people were Cruithni, or Picts of the Goidelic branch of the Celts; in the east and centre, British and Belgic tribes; and in Munster, when not distinctly Iberic, of a southern or Gaulish type.

The fertile plain lying between the Wicklow and Carlingford mountains, and especially the part of it south of the Boyne (Mag Breg), was open to tribes coming from the opposite coast, and has accordingly been at all times a landing place of invading tribes. This region was occupied by the tribe of Nemed before the arrival of the Firbolgs, if we believe the legend; but the event certainly belongs to a later period, though still to the time of the movements and displacement of peoples which led to the immigration of those tribes. The Fomorians, with whom the Nemedians fought, may have been merely some of those incoming tribes. The Irish legend brings the Nemedians from the east of Europe, which of course only means that they came from a distance, perhaps from Armorica or some other part of Gaul. Nemed's tribes were probably the builders of the tumuli of Meath, and the introducers of the worship of Dia and Ana, in other words, they were the mysterious Tuatha Dé Danann ("tribes of Dia and Ana"). Nemed was probably only another name for Dia, and his wife was Macha, an appellative of Ana. The name Nemed itself is of great interest, for it is evidently connected with *nem*, heaven, used also in the secondary sense of a sacred object upon which oaths were sworn.

---

[1] They were, however, only subdued, for long after there were Firbolg kings of Olnegmacht (the ancient name of Connaught), and the people were very numerous in Ireland in St. Patrick's time; indeed, it is probable that they then formed the largest element of the population.

The Milesian legend seems to consist of two or perhaps of three events. Eber and Erimon, two sons of Galam, or Milesius, the leaders of the invading forces, fight a battle at Slíab Mis in western Kerry with Eriu, the queen of Ceitheoir or Mac Gréne, "the son of the Sun," one of the three joint kings of the Tuatha Dé Danann, whom they defeat. Eber or Heber then marches to Tailti in Meath, while his brother Erimon or Heremon sails round to the mouth of the Boyne, where he lands and marches to meet his brother advancing from the south. This skilful strategic movement betrays the late invention of the legend. The first fact that underlies the story is the incoming of some powerful and well-armed tribe who seized upon the plain between the Liffey and the Boyne, and made it the centre of an encroaching power. The eponym of this tribe was Erimon, a name foreign to the pantheon of the tribes of Dia and Ana.[1] The new tribes arrived in Ireland towards the close of the prehistoric period, and not long before the beginning of the Christian era, or possibly as late as the first century of it. They were Goidelic, and were related to the dominant clans of Munster, and the Clanna Rudraide or Ulster clans, though perhaps not so closely to the latter as to the former. When the sons of Galam had defeated the kings of the tribes of Dia and Ana, they partitioned Ireland between themselves and their kinsmen. Erimon got Leinster and Connaught; Eber Find, his brother, North Munster; Lugaid, son of Ith, brother of Galam, South Munster; and Eber, son of Ir, son of Galam, the progenitor of Rud or the Rudraide, the immediate eponym of the Ultonians, Ulster. Eber Find, the leader of the North Munster tribes, and Lugaid of the South Munster ones, were grandsons of Breogán, the stem-father of all the new tribes. A long struggle took place between their descendants, in which those of Eber Find ultimately gained the upper hand, and the descendants of Lugaid were gradually pressed into a corner of the county of Cork. This struggle and the position of the tribes of Eber in the plain of Munster seem to show that the latter were, what the legend pretends, a part of the incoming tribes which we shall henceforward call Scots, and which landed, not in Kerry, but in Meath. The places supposed to have derived their names from the forty captains of the invading Scots, such as the plain of Brega, Slíab Cualand, etc., are all in that part of Ireland already spoken of as the landing place of invading tribes, or in the great central plain stretching west and south-west from it. There seems little doubt that these clans of Breogán or Scots were closely related to the Brigantes, perhaps they were even tribes of that great clan. The Brigantes who occupied the basin of the Barrow and Nore, and ultimately the county Waterford, according to Ptolemy, support this view. The clan of Lugaid, grandson of Breogán, is almost certainly that which used the Ogam inscribed stones, the last that came into the country, and with which originated the story of the migration from Spain.

The Scoti.—The opening of the historic period was marked by a great struggle of tribes, which took place about the beginning of the Christian era, and of which Irish annalists have left us but very scanty information, and that confused and misleading. This struggle was brought about by the arrival from abroad of a new tribe, or the rise of an old one. The former view seems the more probable, for at that time great displacements of the Celts were taking place everywhere consequent on the conquests of the Romans, and some of the displaced tribes may have migrated to Ireland. The victors in the struggle appear afterwards as Scots; the conquered tribes are called *Aithech Tuatha*, that is, vassal tribes, because they paid *daer* or base rent. The names of the free and servile clans have been preserved, and were first published by the present writer.[2] The former consisted of forty-six tribes, among them being the Scotraige or Scotraide. This tribe probably took a foremost place in the subsequent invasions of Britain; and, it having thus acquired the leadership of the free clans, the latter became all known to foreigners as the Scoti, a name which was subsequently extended to the whole people. That this was the way in which the name was first given is shown by its not having been used in Irish, but only in Latin documents. The ending *-raige* or *-raide* is a patronymic.

In the struggle between the free and servile tribes the latter appear to have succeeded in throwing off the yoke of the free clans or Scots, but after some time the latter, under the leadership of Tuathal, called *Techtmar* or "the Legitimate" (*ob. cir.* 160 A. D.), recovered their power and took effective measures to preserve it by making some kind of redistribution of the servile tribes, or more probably making a plantation of Scots among them, and building fortresses capable of affording mutual aid. The duns and raths on the great central plain of Ireland to which Tuathal's measure was probably confined appear to have been erected on some strategic plan of this kind, intended to keep up a chain of communication, and prevent the combination of the servile classes. Tuathal in fact founded a kind of feudal system which ruled Ireland while the Scotic power endured.[3]

Another measure of Tuathal was the formation of the kingdom of Meath to serve as mensal land of the Ard Rí or over-king. Before his time there was, according to legend, a district about the sacred hill of Usnech called Mide, that is, "the middle," the religious centre of the Irish; this Tuathal enlarged by taking from each of the four provinces—the two Munsters being reckoned as one—a tract of land. In the Munster portion he built his Dun of Tlachtga, a sacred place of the Druids, now called the Hill of Ward, near Athboy. Usnech was considered to be in Olnegmacht (Connaught). Tailti (gen. Tailtenn, now Teltown) was his Ulster residence, and Temair or Tara the Leinster one. Tuathal made each of those places a religious centre for the province from which it had been taken.[4] He was thus not only the founder of the central monarchy, but also it would seem the organizer of the religious system of the people, which he used as a means of securing the allegiance of their princes by holding their chief shrines in his power, while leaving them the rents derived from them. An act of Tuathal, which marks his power, and the firm grasp which he had secured over the country, was the infliction of a heavy fine on the province of Leinster, a legend tells us, for an insult offered to him by one of its kings. This fine, called the *Boroim Laigen* or Cow-tribute of Leinster, was levied until the 6th century, when at the instance of St. Moling it was remitted by the monarch Finachta. It was a constant source of oppression and war while it lasted, and helped to cripple the power of Leinster. Several attempts were made to reimpose it, among others by the celebrated Brian, who, according to some, derived his surname of Boruma from this circumstance. To carry out his measures of conquest and subjugation, Tuathal is credited with having established a kind of permanent military force which afterwards became so celebrated in legendary story as the Fíann or Fenians. He may have seen Roman troops, and attempted as far as his circumstances would permit to form a military tribe organized somewhat after the manner of a legion. Among the other measures attributed to Tuathal was the regulation of the various professions and handicrafts. The former he must necessarily have done as part of his religious organization, for the various professions were merely the grades of the Druidical hierarchy.

---

[1] Herr Mannhardt connects Erimon with Irinc or Irmin, a god or divine hero of the Germans, and both with Aryamo (Aryamân), the deified ancestral king of the Hindus, who ruled Elysium, and whose path was the Milky Way. He also thinks that these words as well as Eriu contain the same stem as Aryan, and that consequently Aryamo may have been at one time the national god of all Aryans. Some curious particulars might be added here respecting Donn, the brother of Eber and Erimon, which appear to give great interest to this hypothesis.

[2] In O'Curry's *Manners and Customs of the Ancient Irish*, Introduction, vol. i. p. xxvii.

[3] The Aithech Tuatha, or servile tribes, have been identified by some antiquarians with the British tribes known as Atticotti. The ground of this surmise is the resemblance of the names. Although the explanation we have given of the name is satisfactory, it is right to state that among the servile tribes there was one called the Tuath Aithechta, which might have given its name to the whole of the servile tribes, as the Scotraige gave theirs to the "free clans." This tribe was seated on the sea-coast near the Liffey, and there is nothing improbable in the notion that when beaten they may have crossed over to Britain, where they became known as Atticotti, and were associated with the Scots in their devastations of the Roman provinces.

[4] Thus the great Druidical festival of Samuin (now Allhallowtide), on which occasion all the hearths in Munster should be rekindled from the sacred fire, and for which a tax was due to the king, was celebrated at Tlachtga. At Usnech, now the hill of Usnagh in Westmeath, the festival of Beltaine was celebrated in the month of May. The horse and garments of every chief who came to the festival formed part of the toll of the king of Olnegmacht. At Tailti a great Oenach or fair was held at certain intervals on the first of August, at which was celebrated the Lugnasad, the games supposed to have been established by Lugaid of the Long Arm, one of the gods of Dia and Ana, in honor of his foster mother Tailti. Here for the first time Tuathal erected a dun, thus securing possession of the shrine of the Ulaid, to the king of which the rents of the fair belonged. These consisted chiefly in a fine due for each marriage celebrated

The Rival Kingdom of Munster.—If we accept the story of the plantation of the broken Aithech Tuatha, Tuathal's power must have extended over the whole country; but it was practically confined to Meath and Leinster, and perhaps Olnegmacht. Ulaid was independent. In Munster the clan of Degaid had conquered a large tract of country in the middle of the province, and forced the clan of Dergtind or descendants of Eber into the south-west of Cork and Kerry. The origin of the clan of Degaid is obscure; one story makes it Ultonian, and the other Erimonian. The latter is probably the true one, for among the free clans associated with the Scotraige in the war of the Aithech Tuatha was a tribe called Corco Dega, which seems to be the one we are now discussing. The clan of Degaid, having dispossessed a non-Scotic tribe called the Ernaans, were themselves afterwards known by that name. From their peculiar position in the south they must have acknowledged the supremacy of Tuathal and his successors. In the reign of Cond, surnamed "of the Hundred Battles," grandson of Tuathal, the clan of Degaid had succeeded in getting the upper hand of the clans both of Eber and Lugaid; and Munster, now divided into three petty kingdoms, was ruled over by three princes of that family. A chief of the Eberians named Eogan, better known as Mug Núadat,[1] by the aid of his foster-father the king of Leinster, succeeded in defeating the Degaidian princes and driving them out of Munster. The latter asked the aid of Cond the over-king, who took up their cause, and a fierce war arose, in which Cond was beaten and compelled to divide Ireland with his rival. The boundary line ran from the Bay of Galway to Dublin along the great ridge of gravel which stretches across Ireland. The northern part was Leth Cuind or Cond's Half, and the southern part Leth Moga or Mug's Half. By this arrangement the present county of Clare, which had hitherto belonged to Olnegmacht, was transferred to Munster, to which it has ever since belonged. It was about this time too that the former province received the name Connacht, now Connaught, from the name of King Cond. In the wars between Mug Núadat and Cond a considerable number of foreigners are said to have been in the army of the former, among whom are specially named Spaniards. Perhaps these foreigners represent the tribe of Lugaid, and this was really the period of the arrival of that tribe in Ireland out of which grew the Milesian story. The earliest of the Ogam inscriptions are perhaps of this date, and support the view just stated.

Mug Núadat must have been an able man, for he established his race so firmly that his descendants ruled Munster for a thousand years. He seems to have been as politic as warlike, for we are told he stored corn to save his people from famine. He was also enabled to give some to many chieftains who in a tribal community had no such forethought, and thus made them his vassals. His success, however, created a rivalry which lasted down to the final overthrow of the native government, and led to constant war and devastation, and mainly contributed to the final overthrow of the central monarchy. Although Munster remained nominally in subjection to that power, it was thenceforward in reality an independent kingdom, or rather federation of clans under the king of Cashel.

Scotic Conquest of Ulster.—If the Scots failed to subdue the south thoroughly, they succeeded in crushing the Ultonians, and driving them ultimately into the south-eastern corner of the province. One of Cond's successors, Fiacha Srabtine, was slain by his nephews, known as the three Collas, one of whom, called Colla Úas, "the noble," became king about 327; but after a reign of four years he and his brothers were driven out of Ireland. They took military service with their maternal grandfather, a certain Ugari, called king of Alba. After three years in this position they returned to Ireland, and succeeded in making peace with their cousin Muiredach Tirech, who became king after the banishment of Colla Úas. The Ard Rí, in order to give them employment, recommended them to carve out territories for themselves among the Ulaid. Finding an excuse in an insult offered to their grandfather, King Cormac, son of Art, they invaded Ulster, plundered and burned Emain Macha, the ancient seat of the kings of the Ultonians, and made "sword-land" of a large part of the kingdom, which was afterwards known as Airgéill or Oriel. Afterwards the sons of the celebrated Níall of the Nine Hostages, the most powerful monarch of the Scotic dynasty after Tuathal, also carved out principalities for themselves in Ulster which bore their names for centuries:—Tir Conaill, or as it was called in English Tyrconnel, the land of Conall, and Tir Eogain, the land of Eogan, from which has come the name of one of the Ulster counties, Tyrone.

Invasions of Britain by the Irish.—Constant allusions are made in the legends of the prehistoric kings to warlike expeditions to Alba. In the legends of the heroic period an expedition to the Isle of Man forms the subject of one of the tales, in which Cúruí Mac Dáiri, of the clan of Degaid, king of West Munster, accompanied by Cuchulaind, carries off Blathnat, daughter of the king of Man. Crimthand, surnamed Nar's Hero, a prehistoric king just preceding the Aithech Tuatha war, brought back many trophies from abroad which are celebrated in legend. The Annals of the Four Masters, quoting the Annals of Tigernach, tell us at the year 240 that Cormac, son of Art, and grandson of Cond, sailed across the sea and obtained the sovereignty of Alba. This Cormac was a noteworthy king, who ruled with much state at Tara from about 254 to 277 A. D. He is said to have introduced water-mills into Ireland, and to have established schools for the study of law, military matters, and the annals of the country. Laws attributed to him continued in force all through the Middle Ages. A book of moral precepts for the guidance of princes, called *Tecosc na Righ*, is attributed to him, a copy of which occurs in the Book of Leinster, a MS. of the 12th century. Another work compiled under his direction, and containing what may be called the history and geography of Ireland, has unfortunately not survived. He was the enemy of the Filid,

---

there. At Tara, the principal residence, he established the Feis Temrach or Feast of Tara, which was a general assembly of the provincial and other subreguli of Ireland who came to do homage to the ard rí or over-king. This feast continued to be held from Tuathal's time to 554 A. D., when the last was held by Diarmait, son of Cerball. The establishment of this feast is also attributed to the prehistoric king Eochaid Ollam Fotla, which implies that Tuathal merely re-established it.

[1] That is, the slave or servant of Núadu, one of the chief gods of the Góedel.

owing it is said to his having learned something of Christianity in his expeditions. It was, however, during the reign of Crimthand son of Fidach (366–379) and of his successor Níall of the Nine Hostages (379–405) that the Irish invasions of Britain acquired for the first time historic importance. The former was a Munster prince, the most powerful of his race, and the only Eberian prince who was king of Ireland until Brian Boruma (1002). His successor Níall was also the most powerful of the rival race of the Erimonian Scots.

There appear to have been three distinct settlements of Irish tribes in Britain:—(1) of Munster tribes in South Wales, Devonshire, and Cornwall; (2) of Erimonian Scots in the Isle of Man, Anglesey, and other parts of Gwynedd or North Wales; and (3) of the Erimonian Scots, called the Dal-Riada. The Cruithni or Picts of Galloway seem to have been a fourth settlement, but definite evidence on this point is wanting. The first invasion and the extent of the settlement of the Irish in south-west Britain are established by the Ogam inscriptions, and there is other proof besides. The most important piece of Irish evidence is the article "Mug-Éime" in Cormac's *Glossary*, which gives a legend of the introduction of the first lap-dog into Ireland. "Mug-Éime, that is the name of the first lap-dog that was in Ireland. Cairpre Musc, son of Conaire, brought it from the east from Britain; . . . for when great was the power of the Gael on Britain, they divided Alba between them into districts, and each knew the residence of his friend, and not less did the Gael dwell on the east side of the sea quam in Scotica, and their habitations and royal forts were built there. Inde dicitur Din Tradui, *i. e.*, triple-fossed fort of Crimthand the Great, son of Fidach, king of Ireland and Alba to the Ictian Sea, et inde est Glastonbury of the Gael, *i.e.*, a church on the border of the Ictian Sea (the English Channel). . . . And it is in that part is Dinn map Lethain in the lands of the Cornish Britains, *i.e.*, the fort of Mac Liathain, for *Mac* is the same as *Map* in the British. Thus every tribe divided on that side for its property to the east was equal [to that on the west], and they continued in this power till long after the coming of Patrick." The Cairpre Musc here mentioned was son of Conaire, son of Mug Láma, of the Degaidian race of Munster, and his visit to Britain took place during the reign of Cormac, son of Art, and when Ailill Fland Beg was king of Munster. As the latter began his reign about 260 A. D., and the former died about 277, the visit lies between those dates. It appears therefore that the occupation of south-west Britain by the Munster Góedel began at least a century earlier than Crimthand's time. The reference to the occupation of Cornwall is curiously corroborated by the story of Tristan and Yseulte, in which Morault is sent by the king of Ireland to collect tribute from the king of Cornwall. British and Welsh records are equally explicit about this occupation. The earliest edition of the *Historia Britonum* (represented by the Paris MS.) dates from 675, according to the Rev. D. Haigh, who attributes its authorship to Gildas, and gives the date of its composition as 471. If we were certain that we had Gildas's work we should have almost contemporaneous evidence, but, whoever wrote the work in question, the actual MSS. are of such antiquity that their authority on the point we are discussing is of great value. The passage referring to South Wales is as follows:—"But the sons of Liethan possessed the country of the Demetians (Dyfed), and other provinces Guoher (Gower) and Cetgueli (Kidweli), until they were expelled by Cuneda and his sons from all British territories." This statement bears out that taken from Cormac respecting the name of the leaders of the Góedel in South Wales. The name Liathan is of great interest, because it is the eponym of an important Munster clan, the Húi Liathain, whose territory Crich Liathain included the barony of Barrymore in the county Cork. The *Historia Britonum* further tells us that Cuneda and his eight sons came from a region in the north called Manau Guotodin, probably about the end of the 5th century. The Welsh traditions referring to the Goidelic occupation of Britain, though contradictory and irreconcilable in their chronology, confirm all that we have said.

Camden, Edward Llhyd, and others pointed out a Goidelic element in the topographical nomenclature of west Britain, and concluded that the country was once occupied by the Góedel, whence they were driven into Ireland by the advancing Cymri. This was a natural and reasonable conclusion at the time. But our present knowledge compels us to adopt a different view, namely, that, without prejudice to the existence at an anterior period of Goidelic tribes in west Britain, the numerous traces of Goidelic names found there are derived from an Irish occupation in historic times. The Rev. W. Basil Jones (now bishop of St. Davids), who by his valuable book, *Vestiges of the Gael in Gwynedd* (North Wales), has so largely contributed to our knowledge of this subject, came to the conclusion that the Irish occupied the whole of Anglesey, Carnarvon, Merioneth, and Cardiganshire, with a portion at least of Denbighshire, Montgomeryshire, and Radnorshire. The same tribes who occupied Anglesey and Gwynedd also occupied the Isle of Man, which, as is well known, was an Irish possession before the Norse invasion. Its colonization is attributed to Manandán, son of Lêr, a sea-god of the tribes of Dia and Ana, and who is associated in the Mabinogion[1] with Gwydion ap Donn and other deities. It would appear that the first occupation of Man, Mona, and Gwynedd took place before the dominance of the Scots, or was the work of Ultonians. But the subsequent importance of Gwydion ap Donn and Arianrod shows that the Erimonian Scots were afterwards the dominant element. South Wales was undoubtedly occupied by South Munster tribes, so that we have the curious historical phenomenon presented in Wales as in Ireland of Mug's Half and Cond's Half. The explanation of this as well as of the occupation itself is no doubt the pressure of the clan of Degaid and other Scotic tribes upon the tribes of Lugaid,[2] causing the greater part to emigrate. By the aid of these emigrants, who had become better armed, Mug Núadat and his successors on the Munster throne were enabled to recover their possessions in Munster again. It was no doubt by their help that Lugaid Mac Cuind of the South Munster clan succeeded in defeating Art, the son of Cond of the Hundred Battles, and becoming king of Ireland. The occupation of North Wales was probably due to a similar pressure of the Scots upon the Ultonians.
